Addresses

C DAY'S CRUSADE AGAINST CONSUMPTION.*

ALBERT PHILIP FRANCINE, A.M., M.D.
Staff of Henry Phipps Institute, Examining Physician to the White
Haven Sanatorium, Instructor in Medicine and Physician to
the Medical Dispensary, University of Pennsylvania.
PHILADELPHIA.

ophylaxis in pulmonary tuberculosis, that is, its pre-
n, is of such general interest and of such vital im-
ze that the presentation of this subject in a pub-
dress needs no apology. People everywhere are
the preventable character of this disease, and
efore has the interest in this phase of the sub-
n more widespread.

e taking up the subject proper of this paper,
r, I wish to present some interesting figures
he United States Census Reports 11 and 12, and
m certain German reports. In the year 1890, 102,-
people died of consumption in the United States;
proportion of over 12,000 per 100,000 deaths. In
00, 111,059 people died of consumption; a proportion
over 10,000 per 100,000 deaths. It will be seen that
er a hundred thousand lives are lost a year through
s dread disease; or, to put it a little differently, one
ath out of every ten is caused by consumption. In
t, more people die of consumption than of scarlet
er, measles, typhoid fever, diphtheria, whooping
gh and influenza, all together. Fully 80 per cent. of
victims of tuberculosis are in the middle period of
, between the ages of 15 and 50. Let us make a very
servative estimate, which is not as fanciful as it may
n, of the actual loss in cash of this army of sick,
pacitated from earning their daily bread. Putting
average daily wage at 75 cents a day, the loss amounts
$67,000 a day; or reckoning the working year at 300
s, and estimating the individual incapacity as being
six months only, the loss amounts to $10,000,000 a
r. When to this one adds the expenditure necessary
physicians, nursing, medicine and burial, the fig-
s become stupendous.

Cornet of Berlin gives some interesting figures on
berculosis for continental Europe, which it may in-
est you to hear. From 1875 to 1894 the deaths from
berculosis in Prussia alone amounted to 1,669,587
ersons, which is equivalent to the entire population of
Philadelphia. The average is about 80,000 a year. In
Austria, from 1881 to 1892, a period of eleven years,
here were 1,059,300 deaths, or about 90,000 a year.
These figures represent a mortality even greater than
e have in this country.

Tuberculosis is more fatal to humanity than dysentery, cholera or the plague. The ravages of war are insignificant beside it. In the great Franco-Prussian war, according to Prussian statistics, the number of men killed and dying of wounds and disease amounted to 40,951. Twice as many die each year in Prussia of tuberculosis. In our own Civil War there were 70,293 lives lost in battle. This is only a little over half the number dying each year from tuberculosis in this country.

But monstrous as is this showing of the direct ravages of tuberculosis, it is not all nor even the worst half of the picture; for you must know that tuberculosis attacks every organ and tissue of the body and accordingly travels under many other names. For instance, it is called lupus when it attacks the skin; scrofula when it attacks the glands; curvature of the spine, or spinal caries, when it attacks the vertebræ; Pott's disease, when it attacks the hip; white swelling, when it attacks the joints; and so on indefinitely. Who, then, can measure the anguish, poverty, degradation and sin which it causes! Our insane hospitals and orphan asylums, our homes and hospitals for crippled children, our reformatories, prisons and penitentiaries are filled with the indirect results of tuberculosis (Flick).

With such facts and figures before us, there can be little need of discussing the advisability of employing measures to suppress this universal pest. That we should adopt all such measures as lie in our power is a self-evident fact. And when I add that we *can* safeguard against it, and that by certain simple measures we *can* cut down this awful mortality it becomes criminal negligence on our part to neglect them.

The general indications for prophylaxis or prevention in pulmonary tuberculosis may be classified as including two broad aims: first, to destroy the tubercle bacillus and prevent its spread in the dried state; and, second, when once it has gained entrance to the body, to eliminate it as quickly as possible, or inhibit its growth by means of the vital energies (Cornet).

Let us consider, first, the means at our disposal to annihilate the organism. The tubercle bacillus, which is the one and only cause of tuberculosis, is unable, except when cultivated artificially in the laboratory, to increase and multiply outside the body of either human beings or animals. This is partly because it requires high body temperatures, and partly because of its slow growth, as it is crowded out of existence by other micro-organisms which grow more rapidly and luxuriantly. Fresh air and sunlight destroy it. It, therefore, exists among us only from being present in (1) the secretions and excretions of tuberculous human beings, and (2) in the milk and meat of tuberculous animals. The breath of tuberculous patients does not contain the bacilli; it is sterile and harmless.

---

* An address given under the auspices of the Henry Phipps Institute, in Carnegie Hall, Pittsburg; and to the students of the Medical Department of the University of Pennsylvania.

The bacillus gains entrance to the human system, first, and most frequently, from tuberculous matter given off by consumptives after it has become dry and pulverized, and the bacilli, diffused in the air, are then either directly inhaled or taken into the gastro-intestinal tract; and, second, from the use of infected meat or milk. Tuberculosis is very rarely transmitted by heredity.

Infection from the use of tuberculous meat or milk is not likely to occur where there is careful inspection of dairies, slaughter houses and herds. It is also guarded against by cooking the food. The great omnipresent danger lies in the inhalation of tubercle bacilli as they float in the atmosphere of contaminated places, halls and rooms of dwelling houses, factories or other poorly ventilated buildings, which have become infected by expectoration of tuberculous material. Other excreta may contain tubercle bacilli. It may be given off from the drying of feces, of pus from areas of tuberculous suppuration, from particles thrown out in the act of coughing; but these are all negligible quantities compared with the all-important source of infection in dried sputum.

Before proceeding, however, with the prophylaxis of the individual, let us for a moment consider the interest of the state in tuberculosis. We have seen from the statistics which have already been given that this matter is of such vital interest and of such widespread importance that, without aid from state and municipal authorities, the profession, even seconded by an intelligent public, is powerless to stop the spread of this scourge. We, therefore, turn, as we have every right to do, to those bodies politic which assure to each and every one of us life, liberty and the pursuit of happiness. The only question to be asked is, How can the state help in this crusade? It can help in three most important and effective ways: (1) By establishing sanatoria for the segregation, treatment and employment of those cases which are too poor or ignorant to take care of themselves and in whose carelessness, squalor and filth lies the chief source of infection. (2) By rendering effective financial assistance to free, private or corporate sanatoria already in existence. (3) By requiring the registration of every case of tuberculosis within its confines.

The state sees and performs wisely its duties in protecting us from the spread of smallpox, scarlet fever, diphtheria, typhoid fever and other contagious diseases, the yearly ravages from which are not individually one-tenth of, and in the aggregate do not equal, the mortality of tuberculosis. Why, then, should it not in certain simple, timely and reasonable ways see its way clear to these more urgent measures. There should exist in all states adequate sanatoria accommodation for the tuberculous poor of the commonwealth. Whether this can best be done by free institutions founded and maintained by the state, or by free private institutions fostered by state aid, is an open matter of dispute. These free sanatoria should be placed in suitable localities in different sections of the state, and should, of course, be under expert medical and sanitary control. There are at present in Pennsylvania, counting city institutions as well as those in the country, at the most 1,000 free beds for consumptives. The present need is for at least five times that number.

One has only to turn to the records of existing sanatoria, of which the free hospital for poor consumptives at White Haven may be taken as a model type, to see the splendid results achieved. Both private and state aid should be freely given to such institutions; f their expenses are always very great. Their cottag and tents are always filled, and they have demonstrate that this is the best and most effective treatment w have to-day for a large class of cases.

In public or state sanatoria, did they but exist, or i free sanatoria supported by private charity, could they b enlarged and given increased means, the afflicted poo who infest our slums and die miserably by the hundred could receive the care and treatment they require. Wha a gain to them! What a gain to humanity a large! It is these overcrowded lodging houses and tenements in the poorer sections of our cities, plague spots which furnish the ever-present foci and source of th disease!

For tuberculosis is pre-eminently a house-bred disease. It is not contagious in the ordinary acceptance o that term. In the vast majority of instances it is contracted from living in a room or a house which has been previously contaminated or is being contaminated i the carelessness of a consumptive. It requires a pr longed exposure for a successful implantation or inoc lation with the tubercle bacillus. There is little if an danger in transient association with consumptives, transient exposure to contaminated places. Physicia are in little or no danger from their examination of an attendance on the tuberculous sick. You can not contract consumption from riding in a street car, nor eve from sleeping a night or two in a berth on a railroa train or boat which has been previously occupied by consumptive. All such ideas of the danger of consumption come of ignorance and exaggeration.

But it is the plague-invested areas of the slums which keep the disease continually alive; the filth and overcrowding, the squalor and starvation, which furnish the fertile soil for the disease. Many of you know, no doub the small tumbledown houses and the dirty tenement in which the really poor live; the cheerless, ill-ventilate rooms, the dark,narrow halls. There was a filthy, contaminated house, not unlike many others, which I happen to recall bcause it was so near the Phipps Institute There were six or eight deaths a year from tuberculosi from this place alone. The average number of occupant to a room was four. I knew of two families of seven in two rooms, five of whom had consumption. How long would it take these five people, even if there were no other cases, to contaminate that whole house! The average length of residence in one place among the poor is about two or three months. How long would it take anyone coming into such quarters to contract the disease! Is it any wonder that with these ever-present foci of infection, tuberculosis numbers its victims by the tens of thousands, and that the ranks of this great army of death are always filled?

The period at which consumptives are most dangerous to their families and to the community is when they are far advanced in the disease and are very ill. Then it is that, while expectorating a great deal, they are too ill or careless to take the precaution of destroying their sputum and so guarding others from its dangers. It is especially at this time that they should be removed from their squalid surroundings and placed in city institutions. Sanatoria are necessarily limited to incipient or moderately advanced cases, which will get better in from three to six months, and they must be supplemented by city hospitals for advanced dying cases.

It is in this latter way that the wards of the Phipps Institute are doing such a great work, not only in arresting the disease in apparently hopeless cases, but in taking these cases away from their filthy surroundings just at the time when they are most dangerous to others.

In this connection dispensaries for out-patients or ambulatory cases should also be mentioned. They, too, are most potent factors in the restriction of the disease, because, aside from the benefit patients receive from treatment in dispensaries (and this is very great), they are also taught how to take care of themselves and protect others from infection.

Finally, just a word about registration. It is absolutely essential for the authorities to know the location and distribution of these cases in order that they may carry out disinfectant measures where such are necessary. It is not with the idea of making outcasts of these afflicted poor, but rather with a view of preventing them from becoming such. These cases among the ignorant should be protected from the isolation and neglect to which an unreasonable fear of their condition often subjects them. Registration would not mean municipal interference with private rights or personal liberty, but would enable urgent measures to be taken to clean and disinfect the houses and localities in which the disease is thickest, and to educate the householders themselves as to the real source of the danger.

Let us now take up the question of private prophylaxis or prevention. The interest or duty of the individual in prophylaxis concerns us even more vitally than the duty of the state in this regard. It is here that each and every one of us has the opportunity, and our duty is plain, to help along this great crusade. The keynote of what I shall say in regard to individual prophylaxis lies in the fact that the tuberculous person is himself the origin and source of the danger, and that it is well within his power, by the exercise of a little care and a few simple rules of hygiene, which will in no way interfere with his comfort, to control absolutely the spread of the disease from himself (Cornet).

As I hinted above, the most important element in private prophylaxis is the absolute destruction of tuberculous sputum. It is absolutely essential that it should not become dry and pulverized, thus permitting the bacilli to be disseminated in the air. Tuberculous sputum is, as a rule, enveloped in a viscid bronchial mucous, which contains the bacilli in enormous numbers and retains them as long as it remains moist. When it dries, however, and becomes pulverized, as is apt to occur when it is expectorated on the floor or into handkerchiefs, or rags, millions and millions of bacilli, death lurking in their presence, are disseminated in the air. The danger from the drying of sputum is much more imminent in closed or poorly ventilated places. The bacilli may be directly inhaled as they float in the atmosphere of the infected room or house, or may settle in the dust to be later stirred up and inhaled or carried directly to the mouth by contaminated hands or food and so ingested into the stomach.

Is it possible to guard against this prolific source of infection? The answer is *yes*, and very simply and easily, viz., the absolute destruction of sputum. This can be accomplished just in one way, by the use of paper spitboxes and paper handkerchiefs. In this way, and only in this way, can the consumptive absolutely control the danger. When indoors, patients should without fail expectorate into these. For the street, they should carry paper handkerchiefs and a small paper bag, into which the former are placed when used, the whole being burned as soon as the house is reached. Subjects of this disease should absolutely avoid spitting into rags or ordinary handkerchiefs, as the sputum dries quickly, and this is not only a source of infection for others, but of reinfection for the patient himself. Inasmuch, too, as during the act of coughing, particles of sputum are thrown forcibly out, a paper handkerchief should always be held over the mouth when coughing.

The use of spittoons should be avoided, because absolute control of the sputum and its sure destruction is not possible under these circumstances. Spittoons lead to carelessness and are very difficult to disinfect. Unless the greatest care is used in burning the contents and the vessel is subsequently sterilized in boiling water, the spittoon is more apt to be a source of menace than of security. Another objection lies in the difficulty of expectorating precisely into a spittoon and not on to the rim or surrounding floor or carpet. One has only to note the condition of cuspidors in public places frequented by men to appreciate the significance of my remarks. Indeed, they are worse than useless and rather predispose to infection than protect against it.

The importance of destroying the sputum can not be exaggerated. Cornet says: "According to my experience, bacilli are found in the immediate environment of consumptives, only in case they make use of handkerchiefs or spit on the floor, and never under other conditions." This is an important statement when one considers that Cornet is one of the greatest authorities in Germany on tuberculosis and was the first to demonstrate the presence of tubercle bacilli in rooms and wards occupied by tuberculous patients. It might interest you to hear how he did this. He placed plates in the places which he had reason to believe were infected, and allowed the dust of the room or factory to settle on them. He then collected this dust and inoculated guinea-pigs with it, with the invariable result that from the dust of infected places the pigs developed tuberculosis and died.

A consumptive's sputum is not only dangerous to others, but to himself. By inhaling fresh tubercle bacilli or swallowing his sputum, fresh foci of infection are set up, on the one hand in the lungs, and on the other in the intestines. He can not be too careful on his own account, and it is a good plan for him to wash his mouth and hands thoroughly before taking food, in order that no stray particle of sputum may be carried into the stomach. On this point Cornet says: "The tuberculous person lives at the center, as it were, of the infectious circle which he himself creates, and so imperils himself more than any other. He really commits a slow suicide by carelessness."

Physicians should discourage the marriage of tuberculous persons. A wife, or child occupying the same room with a tuberculous husband or father, is almost sure to contract the disease. An individual, the subject of tuberculosis, should occupy a room alone.

Physicians and others should wash their hands thoroughly after examining or being about tuberculous patients. Nurses who have to do with these sick can not be too careful not to carry their hands to their lips. It is a good plan when in an infected room or house to breathe as much as possible through the nose.

The bedding, towels and clothing of tuberculous patients should be frequently changed, and when soiled put into boiling water or disinfected by live steam. The vessels of the toilet or table articles should be thoroughly disinfected in boiling water.

The use of disinfectants other than fire, boiling water and steam is unsatisfactory and incomplete. Powdered lye may be used to put on sputum which has been expectorated on the floor. It does not destroy the bacillus, but dissolves and disintegrates the sputum mass and enables it to be taken up with soap and water. The best disinfectant for the hands is soap and water and a stiff scrubbing brush. In a general way it may be said that solutions of carbolic acid or corrosive sublimate are useless for the hands, as they are when applied directly to the sputum. They serve only to incase the bacillus in a firm albumin coagulum from which they eventually emerge on drying as lively as ever. Chlorinated lime and the milk of lime are useful to mix with contaminated excreta, and whitewash is a good disinfectant applied to the walls of a cellar. For the purpose of disinfecting rooms, however, the best agent is, first, thorough cleansing, followed by formaldehyd gas. Formaldehyd in solution, while inferior to lime, is also useful. We are thus reduced, briefly, to the following measures or solutions:

(a) General measures—fire, boiling water, steam, formaldehyd gas; (b) local measures, absolute cleanliness, soap and water, lye, chlorid and milk of lime and formalin.

Bedrooms and sitting rooms should be frequently aired and have all the sunlight possible admitted. They should not be dusted, but the walls and furniture should be wiped down moist. They should not have curtains at the windows, nor unnecessary hangings nor drapery of any kind. The floors should be bare or only covered by rugs, and the windows, except in very cold or wet weather, should be kept open both day and night. A room or house in which a consumptive has lived and died should be disinfected with as much care, according to established methods in such cases, as if he had died of smallpox or diphtheria.

Perhaps it would interest you to hear how we practice prophylaxis at the Phipps Institute. Each patient is given a sputum cup as soon as he enters the hospital and is instructed in the importance of its use. He is also carefully instructed in other details of personal cleanliness. The hospital building itself, floors, walls and stairways from garret to cellar are wiped down every morning with moist mops and cloths. Each bit of furniture and woodwork is treated in the same way, even the doorknobs are not forgotten. All bed linen, towels, wearing apparel after being used are put immediately into large bags and immersed in boiling water.

Not the least part of the prophylaxis relates to the out-patients to the daily clinics. At the first visit of each patient he is given a sputum cup and paper handkerchief and bags for the street. In his history he replies to the following questions: How many persons in the house? How many sleeping rooms? How many beds? Do you sleep alone? Where do you expectorate when home? When in the street? etc. Then he is carefully instructed as to personal cleanliness and the right manner of living.

Subsequently the home of the patient is visited by an inspectress from the institute, who examines into the conditions as they actually exist and makes a report. She reinstructs the patient and his family and posts the rules of the institute on the wall.

In regard to the second indication in prophylaxis as indicated above, i. e., to inhibit the growth and destroy the bacillus after it has gained entrance to the body, by means of stimulating the vital energies, or the natural immunity of the individual, we must here trespass a little on the domain of the cure or treatment. You must know that all animals, including man, enjoy a certain amount of natural immunity against tuberculosis; in other words, have a certain amount of natural resistance against its invasion. If this were not so, many more would have the disease than do, for there can be little doubt that the seed of infection is often sown when it does not thrive. This resistance to infection may be increased or diminished by the circumstances of the patient's life. For instance, confinement and overwork, mental worry or strain, loss of sleep and poor food, all contribute to reduce the natural resistance; while a healthy, out-of-door life, with plenty of fresh air and exercise, long hours of rest and good food, all tend to increase the natural resistance of the organism. It is by the application of this principle in the treatment of tuberculosis that we obtain such happy results to-day. The percentage of cures is much greater than it has ever been before.

Tuberculosis is not, as a rule, hereditary in the sense of being directly transmitted from parent to offspring. Rarely, however, it is congenital through the mother. But, on the contrary, the view held by Dr. Flick is that children of tuberculous parents when born after the parents, one or both, have had the disease, enjoy to a much higher degree this power of resisting the infection than do others. So firm a believer is Dr. Flick in this theory that he says he is always relieved to find such a family history in a patient. In other words, he thinks that you have inherited in your organism and blood a greater resistance if your father or mother or your grandfather or grandmother have had consumption before you. The reason why children of tuberculous parents so often develop the disease and die is that throughout their early childhood they are subject to such a constant source of infection in their homes.

You will reply that even when taken from home and the environment of their parents early and brought up elsewhere such children frequently die of consumption. This is true, but the answer is that they have been infected early, not with the disease itself, but with the cause of it, the tubercle bacillus; and have carried in their bodies for years, frequently in tuberculous retroperitoneal or bronchial lymph glands, the germ of the disease. This has only awaited a favorable opportunity to break forth and infect the lungs through the lymph channels or the blood. Such an opportunity is furnished by ill health, or a bad cold, an attack of the grippe or pneumonia, and eventually they perish.

RECAPITULATION.

Let me, then, briefly recapitulate and I am through. The most general and fatal disease of mankind is tuberculosis (consumption). One-tenth of all people fall victims to it. In America alone over 110,000 people die of it annually. The disease originates through the inspiration or ingestion of the germ of the disease, the tubercle bacillus. Infection usually occurs through the sputum, which contains millions and millions of these bacilli. It is only dangerous when it dries and becomes pulverized and the bacilli are thus disseminated in the air. This most frequently happens when it is spit on the floor or into handkerchiefs. The drying of sputum is a source of danger not only to those who come in contact with consumptives, but also to the invalids themselves, as they are apt to reinhale or reingest the bacteria which they themselves have expectorated and thus infect portions of the lungs or other tissues which were previously healthy. Public measures for the restriction and prevention of tuberculosis are:

1. The establishment of free sanatoria in the country

for the treatment of incipient and moderately advanced cases, and also farms for convalescents.

2. The establishment of city hospitals for the treatment of advanced cases in the wards, and of dispensaries for ambulatory cases.

3. Registration of all cases and thorough disinfection of all houses in which tuberculosis has occurred.

4. Government inspection of dairies, slaughter houses and herds.

5. The organization of societies for the prevention of tuberculosis.

Measures for the prophylaxis of the individual are:

1. The absolute control and destruction of the sputum. This can only be done if the patient spits into paper spitboxes or paper napkins, which are subsequently burned. Spittoons should not be used.

2. Care and cleanliness in the home, in respect of dust and dirt, and in disinfection of articles contaminated by use.

3. Tuberculous persons should sleep alone. The room should have no unnecessary drapery or furniture and the windows should be kept open both night and day.

Personal prophylaxis is inspired by the fact that the consumptive, if scrupulously clean, is not a source of danger even to his immediate environment. If the above directions in regard to sputum are strictly observed, association with consumptives and the care of them is ordinarily without danger (Cornet).

In conclusion, permit me a word of exhortation. There is nothing done without faith, and you must have faith that these things are so, and that the end for which we are striving will be brought about. Remember that it is not a lost cause or a forlorn hope I am offering you. This is a scourge which can be practically eradicated. Believe me, that time will come.

The bloody war in Manchuria is only more terrible in idea and not in fact. The tens of thousands of human beings given over to slaughter for cause which few of them understood is only more appalling in its barbarity and its futility. But here is a grand cause in which you may all fight without injury to yourselves or loss of life, where you may display a greater and a grander heroism, and where the end and reward is a priceless heritage to yourselves, your children and humanity forever. The civilized world to-day stands aghast at the welter of blood in the far east. At our very doors is a greater depth, whose victims are as a hundred to one, which decimates humanity year by year and century after century.

1404 Spruce Street.

LED ASTRAY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PHARMACOLOGY, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

HEINRICH STERN, M.D.

NEW YORK.

A cat, who had lived for years with a family and was beloved by it, on one of his nightly strolls, met an owl. "Oh, bird of wisdom," exclaimed the cat, "how I wish that I had some of your learning! I pray you take me with you on your explorations and be my instructor." "Hoot, hoot," answered the owl; "and what will be my reward?" "I will give you all the mice that I catch," responded the cat, "and I am deemed an able hunter."

From that time on the cat accompanied the owl, sat at its feet and listened to its wise sayings. But with the newly acquired wisdom the cat grew arrogant; his former associations, his simple life, the fireside where he had so long been welcomed, the gentle care of the housewife, were forgotten by him or disdained.

"I am no longer your pupil, owl," said the cat; "learning has made me your equal; take me into the midst of your wise consorts." "Ta, ta," sneered the owl, flapping his wings; "my consorts can fly; can you?" And away he flew.

The disconsolate cat wearily wended his way back to his old home, but the housewife did not recognize him, and at his place on the hearth another cat was warming himself. Left without a home and without companions, the old cat sighed: "Oh, what avail is my wisdom now?"

The moral of this fable in its relation to medicine of to-day is pertinent. In the cat, before he strayed, we may recognize the medical practitioner of old, beloved by his patients who admired his unflinching devotion to his vocation. The owl, the personification of learning, lures the practitioner from well-trodden paths of duty and leads him astray into unexplored regions. There the old ties which bound him so lovingly are sundered, he loses his identity and henceforth must walk apart. He occupies an isolated position now; the old associations are discarded, and when he yearns to take up his duties of yore he must see, to his chagrin, that his place at the hearth of family affection is occupied by a stranger. Thus he strays aimlessly about, disdainfully regarding humble efforts of others, blaming fate for his misfortunes and failing to see in his shortsightedness that he himself is the cause of his passing. He ascribes his political impotence to social ostracism, and his financial débacle to an overcrowded profession, to the proliferation of healing sects, to the craze of self-medication and to a score of other causes, while in reality he is the author of his own ill-fortune, because he has ceased to be a true physician.

The one who addresses you has always worked in the scientific field; he has for years maintained his own laboratories for biologico-chemical study, and he is now the head of an institute for medical research in the city of New York. With all unbiased experimenters he deeply deplores the trend of modern pathology and the meager, definite and employable data furnished to practical medicine by the laboratory. He has no delusions as to the "science of medicine;" he knows that it is still unborn. Moreover, he is aware that medicine, devoid of its religious, mystic, philosophic, sophistic and so-termed scientific embellishments, resolves itself into the art of recognizing disease, predicting its course and ameliorating its various symptoms. Medicine is an art requiring no innate talent and differing from painting and sculpturing inasmuch as it demands no creative force, but may be acquired and practiced by any one possessing clear understanding and common sense. Firstly and lastly, the object of the healing art should be the alleviation of the physical and mental distress of the patient—the true physician is the comforter of the patient. The prognosis takes the second place in practical medicine—the patient and his family are anxious to learn what course the disease will run and how much hope there is for recovery. Thirdly, the diagnosis follows. The least important in practical medicine is the pathology, for which the patient evinces hardly any interest. The patient is really only concerned about the treatment and speedy recovery. How his disease is termed and of what nature the pathologic processes are that take place, these are questions which the patient, as a rule, considers only when the treatment has proved of no avail. To make a correct diagnosis, of course, requires not a little proficiency, and to this fact, no doubt, the widespread customary expression "the science of diagnosis" may be ascribed. But in all earnestness is it not at least as much an art as a science to recognize a disease? Is it not in most instances the personal experience, bedside experience, by which we differentiate the many symptoms and recognize the disease? Take it all in all, how rarely does the general practitioner resort to test tube and microscope, and still, if he be a master in the art of observation, he will know whether he is dealing with a case of typhoid fever or gastric ulcer or pneumonia.

While diagnostics have taught us many new forms of disease and the discrimination of the various forms, it offers no enlightenment as to the causes and conditions which give rise to a symptom-complex, except perhaps those of infectious diseases.

Again, two physicians may have gone through the same course of instruction; they may have seen an equal number of patients affected with similar diseases; they may both be equally well versed in the system of recognized diagnostic principles, but one may be endowed with a finer touch, with a finer ear and a keener perception—faculties which make the artist. He thus becomes a more clever diagnostician. He is the greater artist of the two.

Even the foremost of diagnosticians would not claim that his special branch was a perfect science. He is fully aware how much depends on the personal equation. He has very little real use for one-sided laboratory diagnosis, and only in doubtful and disputed cases will he accept the verdict of the fledgling of the laboratory. He is the artist and is, therefore, impressed with his own importance. He surpasses his colleague, not on account of his greater learning, but through his greater skill, the result of his finer sensory perceptions. If diagnostics were really a complete science in itself, then all clinicians possessing the same amount of experience would be equally good diagnosticians. But we know the fallacy of this presumption.

And what obstacles do we, who strive to make diagnostics a science, encounter! What an enormous amount of clinical material we must have observed, what a mass of pathologic and chemical studies mastered ere we can boast of having attained even the minutest progress in the method of diagnosis which serves to perfect the recognition of but a single characteristic symptom! And, finally, how often, after all, can a perfectly positive diagnosis be made when an organ whose situation makes it unreachable by ear or eye is involved? If all diseased organs could bear witness—I mean not only those which have been subjected to necropsy, but also those which again have become sound—what would remain of our glorious science of diagnostics? We who work in laboratories, in clinics and at autopsy tables must concede, if we are sincere, that the greater part of the diagnostics of to-day really belongs to the sphere of art and not to science.

Let us linger for a moment in the domain of pathology and ask what service, if any, it has ever rendered to the common every-day practitioner of medicine, for it is of him and not of the different specialists I speak. If we come to the point, it is in reality nothing else than the antitoxin for diphtheria which pathology has furnished him. Everything else emanating and taking its root from the science treating of the nature of disease for the purpose of curing the latter has proved ephemeral, in vain, illogical and unscientific.

And now to the prognosis, which, in my estimation, is next to the treatment, the alpha and omega of every patient. Of course, it should be based on the diagnosis of the disease, as has again been stated by Dr. Dock[1] last year in his excellent oration before the American Medical Association. It goes without saying that this would be the desideratum. The case can not always be accurately diagnosed, however, especially at the onset, and not every individual practitioner who is an optimist and a fair therapeutist is endowed with the proper amount of precise reasoning. In the same address, on the other hand, is advocated the principle that "in practical prognosis we must individualize, just as we have to in therapeutics, with the patient's welfare ever the object of our activity." Avowedly, prognosis thus must be looked on and fostered as an art primarily and not as a science.

And therapeutics—what has this main branch of medicine to do with *de facto* science? Very little, indeed. It is true, we presume, we know at this day why quinin acts in malaria; still the drug was prescribed with the same good results and millions were amassed in its manufacture many, many years before Lavaran's discovery of the plasmodia; we also pretend to be acquainted with the specific activity of a number of other drugs, but our forefathers in medicine, not knowing their specific qualities as we suppose we do, have employed them for similar purposes as we on the threshold of the twentieth century. It is certainly most gratifying to understand the pharmacodynamics of a drug—I mean the physical and chemical alterations it elicits in the organism—to know why it exerts a beneficial influence in a specific case. The practitioner, as a class, has never evinced a special craving for this sort of knowledge. He has always been content to know that a certain remedial agent was effective in reducing a certain symptom or set of symptoms. Why this should be so was little concern of his.

All peoples at all times have endeavored to mitigate disease. The sick were nursed and treated ages before one had the slightest conception of the structure of the human organism, not to speak of the various functions. The ancient priest-physicians, though, were adepts in the art of healing, for the people confided in them and the temples of antiquity were resplendent with the gifts of the grateful patients. Systems of medicine have come and gone; one school, one sect, has superseded the other. In principle and theory they might have differed widely; in practice they might have employed discrepant means; their object, however, was always the same; to relieve the unnatural, the distressing phenomena. Internal therapeutics, at all times, in spite of occasional attempts at rational medication, has always been aimed at the symptoms and not at the underlying factors of the disease. And how could or can it be directed against the cause of the disease when this was and is not understood? In this, the bacteriologic era in medicine—an epoch solely due to the perfection of the microscope, the introduction of stains and the methods of pure culture—the subject of rational medicine is again foremost in the mind of the medical fledgling. But what about his rational treatment? Well, for that cough he prescribes codein or some expectorant, for that fever some coal-tar product, for gastric indigestion

---

[1] The Journal A. M. A., June 11, 1904, p. 1540.

(and almost every case of gastric indigestion which I ever encountered was due to carbohydrates) pepsin, and for constipation—well, once in a while cascara sagrada, because one can not always keep the patient on cathartic pills or calomel.

We are not at all justified to speak at this day of our rationalism in the practice of the healing art, for what we are practicing is everything else but rational medicine. The treatment afforded by surgical measures may be rational in as far as it is directed against the cause of the affection. Internal medicine, on the other hand, is still helpless and has to combat the symptoms or the condition. Of course, the adherents of the modern medical fetiches, bacteriology and serumtherapy, if at all, will admit this with great reluctance only. The new graduate recognizes these facts instinctively when he wants to pose as a surgeon. I can not concur with the prevailing opinion that the young physician takes to surgery or to one of the surgical specialties merely on account of the probably greater pecuniary benefit he may derive from their practice. Besides apishness, the feeling of grandeur, the illusion of a resplendent social position and a mediocre intellect, I think it is nothing else but the therapeutic uncertainty and agnosticism fostered especially by the modern pathologic school in which he has grown up that prompts him to cast his lot with quick-results-yielding surgery.

Almost the entire science of therapeutics is nothing else but more or less refined and varnished empiricism, all protests to the contrary notwithstanding. The better a practitioner has trained himself to administer to the immediate needs of the patient the better a physician he is. Those who are adherents of the Vienna School of Medicine, the cunctators in therapy, may have a proper conception of the futility of influencing the course of disease by remedial measures. They may be close observers and shrewd diagnosticians, which by no means stamps them better practitioners, practitioners in the sense of alleviating the patient's mental and bodily discomfort. Is it not quite inhumane to follow to the letter the dictum of Skoda, who said: "We are able to diagnose, describe and understand a disease (when it runs a well-known typical course, I would add), but we must not believe that we are able to cure it by any of our remedies?" Of course, we can not materially influence disease in the great majority of instances, but we can mitigate its symptoms very frequently. The followers of Skoda wanted to be rational, and consequently did not even make an attempt to treat the patient. Was not Boerhave, with all his shortcomings, the greater physician who treated symptomatically and who, when presenting a case at his clinic, could exclaim to his audience: "Hear ye, and admire the power of the medicaments; we have conquered all the symptoms!"

Skoda, on the one, and Boerhave, on the other side, represent the extremes in school-therapeutics of all times. And yet not quite a century and a half intervened between the advent of the two. On both sides consciousness of the ignorance concerning etiologic treatment; on the one side, in consequence, therapeutic despair, lethargy and nihilism; on the other, overestimation of therapeutic influence, drug delusion and enthusiasm and polypharmacy, and on both sides a good deal of credulity, unjustified hope and mysticism.

We know now that most, if not all, the so-called infectious diseases are self-limited. The effect of remedial measures on the underlying condition is nil, or almost so, in every instance. But is this any reason why we should leave the patient suffer? Should not we try to relieve his pain, his fear, his dyspnea, and the many other distressing phenomena? As a matter of fact almost every one of us follows the precept of symptomatic therapy; the very moment, however, we play the good samaritan we are decried by the so-called medical scientists on account of our empiricism, for we employ drugs of the ultimate action of which—in the light of our day—we know but very little.

Possibly I have painted somewhat too darkly, possibly I discriminated too sharply between science—real science—and the healing art. Yet it must be plainly evident to everybody who cares to see that the light of universal science, notwithstanding all radium fanaticism, thus far does not shine, and may never penetrate, into the depths of life and disease, and that the practice of medicine of to-day differs only in degree and not in character from that of our immediate predecessors.

The naive practitioner does neither know nor would he believe this. He imagines himself a man of science and chases after phantoms just in vogue. He weaves theories which can not be proved and swallows everything of a pseudoscientific character as long as it bears the stamp "made in Germany." If a theory, and be it ever so abstruse, absurd and incomprehensible, hails from the land of Virchow, Koch and Billroth, we on these free shores receive it with profound respect, reverence and open arms, and soon become interested in it, more converted to it than its propounders. Verily, another case of being more catholic than the pope.

In his search for that which he considers science—hypothesis and a series of mostly misinterpreted facts which are utterly useless to him in his practical work—the physician of to-day forgets that he is, above all, the confidant and the comforter of the patient and his family. He forgets that his purpose should be to help the sick and that he must be up and doing. He forgets that the sick individual cares little for the bacterium babble and his numberless theories, but that he desires to get well and to be relieved from aches and pains as speedily as possible—at once. He forgets that he is dealing with an individual and speaks of him as his case only. In his ardent quest for that putative science he has lost the most potent charm of the physician—sympathy, that eternal sympathy for the suffering which is often more effective in alleviating the patient's condition than all pain-soothing remedies. He has become coarse-grained and does not seek to hide his callousness from the patient; on the contrary, he tries to impress the patient with it, for is this not the surest way to inspire him with awe and reverential respect for himself, the master of the situation who has deeply quaffed of "science," with which he is saturated?

Can we marvel, then, that his practice dwindles from day to day? Is it thus surprising that we hear of "the passing of the family practitioner" from one end of the country to the other? Small wonder that the refined and sensitive public shuns him by degrees, delving instead into mystic lore and seeking admission into mystic sects! Need we wonder why the lower classes do not consult their physician any longer and buy their patent medicine trash wherever they can procure it cheapest? The patient probably does not doubt the physician's learning, perhaps he would have himself treated by him and pay the (alas!) too modest charge if but a little sympathy, a little mental comfort, were thrown into the bargain.

Sympathy and the skillful execution of his profession make the successful practitioner. Where the physician who is endowed with common sense and humanitarian instincts puts up his tent—there mystic sects and their systems of healing find little following, there the manufacturer of patent medicines reaps no benefit. Such a physician still enjoys the confidence of his patients; he is the father-confessor of the entire family, he is a member of the town council, collects his bills and is a man among men. What a different picture unfolds itself where the fetich of science with its concomitant huffishness, airs and disregard for the patient's welfare has taken possession of the pupil of Æsculapius! There we find a few professors riding in automobiles, drinking champagne and having the pecuniary means to imbibe annually at the fountain the wisdom of Teutonic phantasts, but there we find domiciling in the unfashionable quarters lean and round-shouldered individuals with empty pockets and stomachs waiting for patients in whom they want to inject imported serum; they vegetate and become paupers, or make a dash for liberty and turn book or medicine or insurance agents, or anything else, but hardly ever become true and ideal physicians, because it is not in the nature of the beast. These are the men who in youthful idealism have embraced what they thought to be a definite science, but it proved a fetich which estranged them from their real calling and spoiled their useful career.

For the sake of argument, let us for a moment waive the question whether that which is considered scientific medicine is a real or pseudo science. Unfailingly we will come to the conclusion that too much hypothesis in medicine is averse to the calling of the physician, as it is averse to the devoted exercise of religion. A physician need not, nor should be, the possessor of much complementary or theoretical knowledge; if he has the gift of[2] quick and intelligent observation, together with the ability of associating ideas, if, in short, he is a man of shrewd common sense, it is by no means necessary for him to possess high erudition and scientific attainments to become an excellent practitioner of medicine. A physician of that caliber, even without marching in the limelight of scientific supremacy, may be an ornament to his profession. On the other hand, the physician as a so-called scientist may contribute the most learned (though abstruse and highly hypothetical) dissertations on the special subject of explorations which he has chosen as the task of his life; his presumed, scientific attainments may far exceed those of his humble confrère, the common-sense practitioner; and yet, for that matter, there is no conceivable reason why he should be a greater or even as great a factor in the real progress of medicine. On the contrary, it is more than likely that he so binds himself up with that comparatively narrow circle of vision that pertains to his special branch of science that he is likely to approach everything from his own narrow standpoint, look at everything through spectacles clouded by personal prejudice, try to explain matters of general import—so far as he attempts to explain them at all—from his own special point of view. He may, in fact, dote with the greatest possible application and fervor, with the zest and enthusiasm of the true scientist, on minute details, but fail in the rudimentary principles of the common-sense practitioner. He lacks the power of initiative and force of creation. If nature had ever bestowed these priceless gifts on him he is almost certain to lose them through one-sided study, through concentration on one more or less theoretic subject.

Representatives of theoretical medicine, such as these, will but scantily contribute toward genuine progress in spite of the isolated discoveries which may, at distant intervals, light up their monotonous plodding like an unexpected shooting star in the dreary black of a dismal autumn night. When these hypothetists have once enshrouded themselves in their pet theories and notions, for the nursing of which they may have spent the best part of their lives, it is very difficult and almost impossible for them to give the same up in favor of results attained by the genius of others, faulty though their own researches have proved. In this respect they are veritable champions of retrogression; they obstinately cling to their own doctrines in which alone, they think, salvation lies ensconced, and thus produce a stagnation on the very field the cultivation of which they profess to have elected as their special domain. They thereby brand themselves as representatives of a doctrinary science—a science which has ceased to live, and which in reality is no longer a science from the moment that it is recognized to be false. Essentially great questions which have a true bearing on the health of the individual, the health of the nation, the health of the human race, have never been asked by these representatives of theoretical knowledge, but rather by those practical men who have no time for specifically theoretic pursuits. From this point of view it would appear that the general practitioner who mixes with the people, who looks into the houses, into the beds, and into the stewpan, who knows the world at large, and also the particular world in which he moves, who not only observes things, but also associates them with surrounding circumstances, can contribute far more food for the solution of human problems than his brother who works with microscope and test tube. It is no cause for wonder, then, that the really great questions affecting the natural sciences have never been asked by professional scientists, nor is it cause for wonder that so many medical discoveries have been made—not by those who have devoted their lives to the confines within which the discoveries ranged, but by the unknown practical men who can not boast the highest scientific education, and whose names are not always chronicled on the scroll of fame.

And now you know whom I consider the ideal, the true physician. It matters not to me what he prescribes to accomplish his immediate end, so long as he knows what he is prescribing. I don't care whether the drug which he employs is made in Germany or whether it is compounded in this country, whether it is patented and trade-marked or whether it is simply trade-marked. In this respect, all coons look alike to me. If he finds it convenient to prescribe or dispense a combination of known composition bearing a copyrighted name, that is simply his concern and nobody's else. It is a peculiar taste, I avow, to order something which is trade-marked and which could be dispensed for a small fraction of the price the patient has to pay for the copyrighted article. However, this is the individual practitioner's concern and not mine. He may have weighty reasons for preferring the put-up preparation. Again, will the patient be the financial gainer by obtaining a combination of the doctor's specification, will the dispenser not charge about the same amount for, say, twelve powders whether they contain the copyrighted or a similar article compounded in his shop? To me, the entire question of patented and proprietary medicines of known composition is a contest between the manufacturer and the dispenser, whether the one or the other shall pocket the profits. It is a humane trend to sympathize with the under dog, and thus we offer our moral and material suport to our friend, the druggist at the corner.

---

[2] Part of the following has already been published elsewhere.

We physicians are mighty queer people. Up to the brim we are full of inconsistencies. We may be starting in practice and get along with two meals a day, but we fail to send our bill to the well-to-do father of a colleague, or to the political boss; we are timid and shy, but agitate with all our energy for the erection of new dispensaries and hospitals; we dismiss our colleague's diagnosis of a case with a shrug of the shoulder, and are ourselves supersensitive what others think and say about us; we tear to pieces our fellow practitioner's literary attempts, but we are staunch believers in the moloch of medical authority. We are going astray because we are inconsistent in our daily life, because we have ceased to believe in ourselves. We may live to see our débacle because we are misconceiving our calling, because we have lost our understanding for the real needs of the patient, because we leave the drying of his tears to a nurse, because we make our night calls by telephone. We have so little time for the patient, in the morning we have to make an examination in the laboratory, must be in the surgical amphitheater in the afternoon, must not fail to discuss our neighbor's paper—for he is our good friend—at the district meeting in the evening, and then we must not forget to see the boss, the senator, on account of that job with the railway company.

Orthodox medicine of to-day, with its shallow doctrines—masquerading as "science"—has estranged us from our real calling. Let us tear off that orthodox yoke! Let us preserve our individuality! Observe for yourselves, think it out for yourselves, give your sympathies to your patient and give him your help and don't wait for a specific curative serum. Drop that which medical autocrats have presented to you as "science"; it is an encumbrance on your energy as true physicians, it makes you uncertain in your therapeutic activity, it destroys your belief in the efficacy of your symptomatic procedures without bringing you nearer to the goal of rational medication.

I respect the heroes of the microscope and the biologic test; they, of course, are in deep earnest about their work; they are optimists and Don Quixotes, but their little field is narrow and entirely devoid of paramount stabile facts. The meager results which they have obtained to this very hour are absolutely insufficient to build thereon the superstructure of medical treatment. Will ever their microscopic and biologic testing create for us a new paradise where disease finds its alleviation and cure? Does not the true man of science feel rather sceptical about this? Is not the true man of science a good deal less hasty in proclaiming to a credulous world a new-found fact, is he not one who refrains from enunciating vague speculations thereon?

The more hasty such professional investigators, the more insincere and unscientific they are. Those in subordinate positions, as a rule, are the more conservative ones; they work and are in earnest. It is different with a great number of inflated pygmies in the professorial chairs. Comments made by the *Electrical World and Engineer*, May 27, 1905, anent hasty scientists fit their case admirably. Says this editorial:

> It is now near two and a half centuries since Isaac Newton, in one of the flashes of intuition that form man's best title to mortality, saw disclosed to him the key to the mysteries of space. It was a half lifetime later when, through years of patient study and waiting, data enough had come to his hands to clear his conscience in announcing his discovery. For very truth's sake he gave to the world no half-baked hypothesis nor ventured to exploit with specious arguments a doctrine which did not quite meet all the facts. We do things differently nowadays. How would the great discoverer have fared had he occupied the chair of physics at ——— University, where a monthly blank is forwarded to heads of departments to be filled out with reports on the "researches" they have completed and the number of lectures they have given before women's clubs? Would he have held his peace, or would he have sent for a reporter of the *Daily Saffron* and have filled him full of speculations on the bounds of space and the origin of life? Would he have cut up his great hypothesis into stove-lengths, as it were, to furnish his hustling pupils fuel for frying their theses? Would we have had Prof. I. Newton and Thomas Snoobs, B.S., on "Gravitation in Jupiter," and Prof. I. Newton and Richard Roe, A.B., on "Gravitation and Saturnian System," and so on *ad nauseam*? And would the president have sacked him for insinuating that something in the universe had a more consistent pull than the chief benefactor?

These remarks, called forth by a number of articles on the characteristics of radium, are continued, thus:

> We are far from denying the possibilities of the working hypothesis assumed by Rutherford and his confrères, but what would Newton have done? Would he have left, before developing the results of his hypothesis, any stone unturned that might give him light on its fundamental correctness? Profoundly interesting as are theories of the genesis of the so-called elements, they furnish no adequate excuse for neglecting to examine the elements at hand. Take, for example, the substance radium itself. There is good reason to assign it a definite place among the other elements, and a rational set of chemical and physical properties quite apart from its radioactivity. *Who, of all those who have theorized about its radiations, have any knowledge of the physical properties of the metal,*[3] with the bromid of which they are daily working? *Is there anybody, indeed, who can affirm from actual knowledge that the metal radium is radioactive at all?*[3] Radium salts are, unhappily, costly, the latest newspaper quotation being $3,000,000 per ounce, but the subject is surely of sufficient importance to justify some one in trying to produce a few milligrams of the metal. Again, it seems to be well established that radium salts give off heat spontaneously and steadily, as an accompaniment to their radioactive activity. But there has not yet been any adequate investigation of the actual cause of this thermal energy.
>
> We have had any amount of speculation based on the assumed endothermic properties of radium, including a voluble explanation of the source of the sun's heat and the interior temperature of the earth, but there has not been yet a really serious attempt to determine whether the phenomenon itself is primary or secondary—due to disintegration or to the return of energy received from exterior sources. Everybody seems to have jumped at the former conclusion as the striking and sensational one without further discrimination. Likewise, in the case of radium emanation, we have on good authority the appearance of helium as a decomposition product. Radium has a definite spectrum and so has helium, but, although the spectroscopic study of this mysterious evolution of helium ought to show clearly and certainly the whole progress of atomic disintegration, no word has yet come to enlighten us. The true and faithful student of radioactivity seems to hold old-fashioned chemistry as anethema, and the spectroscope, that magic wand that has turned back the veil from interstellar abysses, as a deceit of the devil. Now the subject is a tremendously important one—we began this comment intentionally with a reference to gravitation—and it deserves the best efforts of the greatest investigators. The

---

[3] Italics mine.

thing which we would impress on them, however, is that hypothesis needs to have its wings clipped a bit just now. It is well to remember Newton's immortal lesson in scientific self-restraint, and to make sure of one's foundations, before building a new heaven and a new earth from anything so elusive as radium emanation.

Yes, hypothesis needs to have its wings clipped a bit just now, especially when it springs from shallowness and is conceived in insincerity. Hypothesis, masquerading as science, is the fetich to force you in the bondage of those who like to have themselves called authorities, but who are too indolent and too sterile intellectually to do original work, to do anything for which cash is not forthcoming immediately. These are the drones in the domain of medicine who arrogate for themselves the meat and magnanimously leave for you the bones. These are the men who have invented for you the worship of the new fetich, "medical science;" these are the men who have led you astray. Like hornets disturbed in their nest, they will resent the intrusion and with the poison of their stings will seek to render futile the purpose of this address.

And once more I implore you: Away with the fetich, down with the false gods!

SINUS THROMBOSIS.

A REPORT OF TWO CASES, WITH MASKED SYMPTOMS.*

HILL HASTINGS, M.D.
LOS ANGELES, CAL.

In presenting these two cases of sinus thrombosis, I desire to call special attention to the following points:

1. The thrombosis in each case, although of otitic origin, was masked by the symptoms of the other diseases,—in the first case by coexisting typhoid; and, in the second case, by a history of malaria.
2. The so-called classical symptoms of sinus thrombosis, namely,—chills, fever and sweats, were not present in either case.
3. The thrombosis in each case was suspected by certain irregularities in the history which led to uncovering and carefully examining the sinus, after the mastoid ablation.
4. The thrombosis was demonstrated in the first case by purposely opening an apparently normal sinus.

Case I.—E. H., a sailor aged 38, was admitted to the Los Angeles Infirmary Feb. 21, 1904, with a temperature of 104.2 and the general symptoms and signs of typhoid fever.

History.—The course of the disease after the patient's admission to the hospital was typical. He was irrational at times and gradually lost his weight and strength. On March 15 a sudden rise of temperature to 104 called for an examination of the ear, from which there had been a purulent discharge. The temperature for the preceding two weeks had been regular, from 101 to 102 in the afternoons and from 99 to 100 in the mornings. The aural suppuration dated back two and a half weeks and followed earache of a few hours' duration. There had been a little pain off and on in the affected ear. The discharge continued and the ear was being carefully syringed. The patient had complained very little of the ear, and it was considered a doubtful factor in the rise of the temperature.

The notes made at the time of my first examination, March 15, are as follows:

"Temperature, 104; pulse, 74; general condition bad; emaciated and weak; answers questions rationally when aroused, but soon relapse into a typhoid condition. The examination of the ears shows a purulent discharge from the left ear, sagging of the posterosuperior canal wall and an inflamed bulging ear drum, with a small insufficient perforation. The mastoid shows no edema or redness. Very slight tenderness is elicited on deep pressure over the antrum and tip of the affected side. The right ear is normal. The nose and throat are in good condition. The eyes are normal. There are no motor or sensory disturbances."

The quantity of the middle ear discharge and the sagging of the posterosuperior canal wall rather indicated mastoid involvement, in spite of the lack of pain or marked tenderness. The drum membrane was freely incised on the following morning to obtain better drainage, in the hope that a mastoid operation could be deferred until there was some improvement in the typhoid condition. During the next three days the temperature fluctuated, the morning temperature being from 99 to 100 and the evening temperature as high as 105. There were no chills or sweats, no vomiting, and the rise in temperature was regular and occurred in the evening hours. The discharge from the ear was profuse. A mastoid operation was finally considered necessary.

First Operation.—Mastoid, March 19, four days after the first aural examination. The mastoid cortex was found hard and not perforated. The superficial cortical cells were full of granulations, but contained no pus. The deeper cells, especially those of the tip, were full of pus. When the antrum was opened several drops of pus welled up. The zygomatic cells contained pus and granulations. A complete ablation of the cellular structure of the mastoid was made down to the hard bone covering the sinus and to the inner plate of the middle cranial fossa. The cells over the sinus groove contained mucopus. The bony plate covering the sinus was found to be hard and intact from the knee downward. Behind the knee it was found somewhat softened, and at this point the sinus was purposely uncovered and examined. It was blue in color, soft, and except for a slight capillary injection of the dural coat, it was apparently normal, and, therefore, was not opened. The mastoid cavity was packed with iodoform gauze and the usual dressing applied.

Postoperative History.—During the next three days the temperature varied from 99 in the morning to 103 in the afternoon. The mastoid wound was dressed and found clean on the second day. On the fourth day the evening temperature again rose to 105.5 without any chill, vomiting or other disturbances, except pain in the opposite shoulder. This pain had been complained of for several days and was so intense as to require morphia. There was no pain in the head, and no pain or tenderness on either side of the neck. Careful examination excluded pulmonary, cardiac or abdominal complications as possible causes of the irregular fever. As the fever indicated septic absorption, it was determined to open the lateral sinus, which, in spite of its normal appearance, might contain a thrombus. On account of the weak condition of the patient the sinus was opened without moving him from the bed. The usual precautions were taken to prevent infection and to control the bleeding. The sinus, where previously uncovered at the knee, was opened with a knife and found thrombosed.

Second Operation.—Resection of the lateral sinus and internal jugular vein. March 24, under ether anesthesia. The bony plate covering the sinus was rapidly removed from the knee downward, as close as possible to the bulb, and behind the knee for about one inch. The sinus wall was thin, not inflamed, and would easily pass for normal. The wall was incised from the opening made at the knee, downward as far as possible and soft clots gently removed. The upper end of the sinus was then curetted of soft clots until a fresh gush of blood occurred from the torcular end. This was controlled by pressure. An attempt was then made to establish a return flow from below by gently curetting the clots from the bulb end of the sinus. Failing in this, it was imperative to ligate the internal jugular. The vein was rapidly exposed and ligated above the omohyoid muscle, and resected from this point upward and ligated about one inch above the facial branch. The part of the vein removed was not thrombosed and no effort was made to resect the thrombosed portion at the jugular bulb. The pulse became so weak during the operation that it was necessary to give an intravenous injection of hot saline solution (130 F.) at the elbow. Hypodermic injections of adrenalin were also given. The neck incision was partly sutured, the usual dressing applied and the patient returned to bed.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Result.—The reaction from the operation was fairly good. The temperature, however, continued high and irregular, but without chills or sweats. Rather as an experiment, antistreptococcic serum was used by hypodermic injections, 20 c.c. at a dose every twenty-four hours during the next four days. No benefit was observed. Low, muttering delirium was more or less constant. Death occurred on March 29, six days after resection of the thrombosed sinus and vein.

Autopsy.—The notes made at the autopsy are as follows: "The body is considerably emaciated. There is a large bedsore over the sacrum. The mastoid wound is clean; the torcular end of the sinus is plugged by a small, firm clot at the cut end. From the jugular bulb a soft clot is pulled out; it does not show septic disintegration. The dura is normal except for some congestion. The cerebrum and cerebellum are normal. The neck wound is clean and free of pus. The ligated upper end of the jugular vein, near the bulb, contains a soft clot. The lower end of the jugular is securely closed by ligature and is normal. The small intestines show several typhoid ulcers, each the size of a dime, near the ileocecal valve. There is no perforation of the intestines and no evidence of hemorrhage."

Microscopic examination of the clot from the jugular vein by Dr. Stanley Black, Medical Department of the University of Southern California, was negative; the examination of the typhoid ulcers showed them to be of several weeks' duration and without any apparent tendency toward healing.

Remarks.—The cause of death was septicemia, resulting from the sinus complication. The septicemia probably had commenced, judging from the temperature chart, as early as March 15, when I first saw the patient. The active typhoid symptoms and the weak condition of the patient obscured the sinus symptoms. The sinus was probably thrombosed at the time of the first operation, when it was uncovered and examined, but not opened. That the sinus wall showed so little evidence of its true condition is possibly due to the fact that the thrombosis did not result from direct infection of the wall by continuity, but through some of the venous channels of the mastoid opening into the sinus.

The second case of sinus thrombosis presents a very different history in nearly every respect and the thrombosis would not have been discovered except for an exploratory mastoid operation rendered necessary by reason of a vague malarial history following an acute aural suppuration.

CASE 2.—A. G., a man, aged 20, was referred from the medical to the ear clinic of the Medical Department of the University of Southern California on account of aural discharge and some mastoid tenderness. He had sought and received medical treatment on account of chills and fever, the ear complication being a complication of secondary importance.

Examination.—At his first aural examination, March 20, 1904, Dr. W. D. Babcock, in charge of the ear department, found some tendencies on deep pressure over the mastoid and turned the case over to me, his assistant, for treatment. The patient stated that his ear trouble dated back two months and a half. It began by buzzing noise and deafness in the right ear. The discharge began six weeks later, without much pain, and still persisted, although gradually diminished in quantity. He claimed to have had a chill three or four weeks before seeking treatment and thereafter a chill every day or two. The examination notes made April 1, are as follows:

"The general condition is good except for some pallor. Temperature, 99; pulse, normal. He complains of attacks of chilly sensations and sweats, and severe pains in the mastoid during the past few days sufficient to prevent sleep. Examination of the right ear shows a scant purulent discharge; a dull red drum membrane, with an oval perforation in the lower anterior segment, no bulging of Schrapnel's membrane; no sagging of the postero-superior canal wall; no granulations. (The appearances were those of an acute purulent otitis media that was subsiding). The hearing is considerably affected in the right ear,—watch, negative, conversation is questionably heard, stage whisper 6 inches; speech 1 inch. The mastoid shows no redness or edema; slight tenderness over the antrum and tip, but acute tenderness on pressure over the emissary vein. The left ear is normal."

The history of chills and sweats for which the patient was being treated in the medical clinic, was then looked into. He stated that the first chill occurred three or four weeks before, while in Mobile, Ala., and that the chilly attacks and sweats had occurred irregularly since then. The attacks were not well marked. There were no sharp paroxysms. He had been taking quinin for several weeks. The tongue was pale and flabby; skin and conjunctiva anemic and spleen slightly but palpably enlarged.

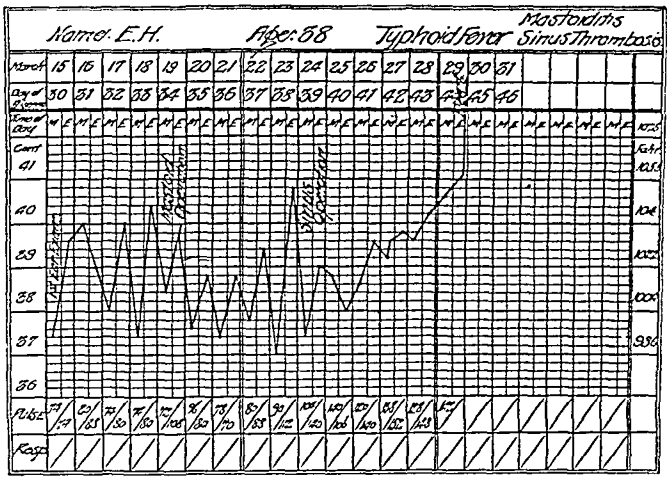
Blood Examination.—Blood smears were made and sent to the laboratory for examination for malarial organisms, and the patient told to report on the next clinic day. The laboratory report stated that blood smears from this patient had been sent in from the medical clinic and malarial organisms recorded as present.

Course of Disease.—By April 19 there was no change in the condition. Vague pains in the mastoid and head persisted. Several examinations failed to show any fever. The aural discharge had about ceased, but the tenderness at the posterior border of the mastoid was quite acute. For this reason, a mastoid operation was advised, after consulting with Dr. Babcock. It was explained to the patient that much or little might be found; and his consent was obtained in writing.

Operation.—April 10, mastoid ablation; resection of the sigmoid sinus. The mastoid cortex was found hard and normal. The subcortical cells were almost obliterated. Hard bone was removed with a gouge for a considerable depth before any mastoid cells were found. These were small, and full of granulations that bled freely. Deep in the tip a cell of some size was opened and contained cheesy material. The antrum was opened through partially sclerosed bone and found to be small and to contain some granulations. A posterior straight incision was made and the flaps reflected. The cortex over the sinus was hard and thick and was removed with a gouge, exposing a small cavity of cheesy material about one inch behind the bony canal. A complete ablation of the mastoid was done down to the hard bony plate covering the sinus and above to the bony plate of the middle cranial fossa. The latter was normal and the dura was not exposed. The cavity was dried and examined. Except for a dark discoloration of the bony plate covering the sinus, deep in the tip, there was no evidence of any diseased structures not already eradicated. The findings had proved to be those of resolving mastoiditis, sufficient to account for the mastoid pains and tenderness. It was remarked that the pathologic changes were those that tended to, and would likely have resulted in, sclerosis of the mastoid.

The history of chills and sweats, however, prompted us to uncover and to examine the sinus in order to be assured that it was normal. The cheesy mass that was found and cleaned out at the tip and the dark color of the bony groove behind this cavity pointed to this region of the sinus for examination. The overlying bone was carefully removed, whereupon some little pus escaped. The sinus was then uncovered from this spot upward to the knee. The wall was found to be covered with a thick, yellow exudate. Below, where the pus came from, there was a small protuberance. At this point the wall was ulcerated, and some of the pus evidently came from the lumen of the sinus. The outer table of the skull was removed along the horizontal limb of the sinus backward from the knee to the extent of 1¾ inches, before there was any appreciable decrease in the amount of fibrino-purulent exudate that covered the sinus and adjacent dura. This exudate and thickening of the dura was so great that it was difficult to make out the margins of the sinus. The sinus was collapsed, as was also the emissary vein, which could be made out. The descending limb of the sinus was incised from the ulcerated perforation below upward to the knee, and found empty. The horizontal limb of the sinus was gradually incised on a grooved director to the extent of 1½ inches. The walls were thick, collapsed, and seemed, as it were, glued together. A grooved director, followed by a curette, was passed backward and toward the torcular to the extent of 1½ inches further, without any flow of blood resulting. It was evident that the lateral sinus was obliterated, probably, as far as the torcular; and it was considered unwarrantable to open the sinus further in this direction. As the pus was in and about the descending part of the sinus, an effort was then made to obtain a flow from below. The sinus' outer wall was cut away and opened as near the jugular bulb as possible. A small curette was gently passed into the bulb end. No clots were found, but a welling up of blood followed the removal of the curette. The curette was again inserted and a better flow of blood followed, and was controlled with a gauze plug. It was not the strong gush that usually follows a return flow from below. It was evident that the lumen at the jugular bulb had been obliterated by the same pathologic changes found above, and been partially opened with a curette. Believing that there was no thrombus in the bulb, it was not considered necessary to ligate and to excise the jugular vein. Both ends of the sinus and the mastoid were packed with iodoform gauze, the posterior straight incision sutured completely and the curved incision left open.

Postoperative History.—The subsequent history was uneventful. The temperature was 101 the day after the operation, 100 on the following day and normal by the third day. No quinin was given after the operation. Investigation showed that the blood examination for malaria, heretofore recorded, was made by a student and was likely unreliable, for there was no further complaint of chilly attacks, fever or sweats. The posterior skin incision over the sinus healed by primary union. The mastoid wound filled in gradually with firm scar tissue. The patient was up and dressed on the tenth day, left the hospital on the twentieth day and went to work at the end of five weeks. There was a slight mucus discharge from the ear thereafter. The small perforation did not heal. The drum membrane became dull white in color.



While I was ill the patient left the city for his home in the East. At that time, May 31, he still had a small funnel-shaped mastoid wound at the bottom of which was the aditus, from which there was scanty discharge. It was kept open in the hope of more quickly healing the middle ear and drum membrane. There was no bare bone and a retaining patch of gauze was worn to hold the loose dressing in the wound. A report from his physician six months later stated that there was still a small, dry sinus behind the ear and a scanty ear discharge. The patient wrote that his hearing had improved rapidly. A letter eleven months after operation stated that he had remained in good health in every way, but that a small sinus and scanty aural discharge had persisted, in spite of frequent curettements, and that a radical operation had been advised in order to heal this.

REMARKS.

A case similar to the second case which I have reported was described by Dr. J. E. Sheppard, at the New York Academy of Medicine, Nov. 21, 1898. In his case, the symptoms likewise simulated malaria and the sinus was opened and found thrombosed as far back as the torcular.

In the first case here reported I regret that I did not open the sinus at the first operation, in spite of its good appearance.

The temperature chart indicates that septic material was then entering the circulation.

I have been able to follow up twelve cases of sinus thrombosis—nine while house surgeon at the New York Eye and Ear Infirmary, and three in my own practice.

It was a striking fact that the thrombosis of the sinus in five patients who recovered was not diagnosed before operation, but discovered by purposely opening the sinus wall on account of its suspicious appearance. This experience is in accord with the statement made by Whiting in 1898, that "the diagnosis of sinus thrombosis in the first stage (thrombus not having undergone disintegration) is, with rare exceptions, consequent on operation for mastoiditis."

I have seen the sinus uncovered purposely or unintentionally 115 times in 198 consecutive mastoid operations, without any bad result. In 69 cases the sinus wall was found to be normal.

I have seen the sinus opened purposely or accidentally, 24 times in this series. In 12 cases thrombosis was demonstrated. In the remaining 12 cases, no harm resulted except in one case which terminated fatally from thrombosis. It is possible that this complication would have resulted, independent of the accident, as it was a badly inflamed sinus wall. The danger from delay in opening the sinus until symptoms of chills, fever and sweats appear, was shown in this series, for all of the seven patients who presented a history of these symptoms died. Many such patients, of course, do recover, but this experience emphasized the fact that the so-called cardinal symptoms of thrombosis are symptoms of a late and dangerous stage, namely, of septic disintegration. I believe that the tendency to terminate the mastoid operation in a case of long standing, or much mastoid destruction, without uncovering the sinus sufficiently to relieve one's mind of doubt as to its condition, is not in accord with good surgical judgment.

DISCUSSION.

Dr. George F. Cott, Buffalo, said that these cases occur from time to time and are often overlooked by the general practitioners. The symptoms are often masked so that it is almost impossible to determine whether or not there is sinus thrombosis. When there is a discharging ear, a phlebitis or thrombus may be suspected; when, however, it occurs in other diseases, the practitioner's attention may not be called to it, because the symptoms may be completely masked. Sometimes in typhoid fever or some other zymotic disease there may be quite typical symptoms of sinus thrombosis that will be overlooked. In case there is no history of ear trouble, it is very readily overlooked. Sinus thrombosis may be caused not necessarily or directly by ear trouble and yet be due to that indirectly. For instance, in a case of chronic ear trouble from which the patient had recovered years ago, acute infectious sore throat may set up an inflammation of the bone, not necessarily affecting the middle ear, and in that way affecting the sinus and causing a thrombus to form without the septic symptoms. The otologist may cut down and mistake the thrombus for a pus sac or something else in the brain. In such cases it pays to explore; one may find some fluid or a little pus. Such patients almost invariably die from septic trouble. When the phlebitis first begins, it depends on the extent of the infection from its source in the ear; if the disease is not checked in some way, by Nature or otherwise, the inflammation extends along the vein and the thrombus gradually forms. That thrombus may extend from the torcula herophili down to the bulb and possibly down the jugular vein. Dr. Cott has seen one that filled the sinus entirely from the torcular to the bulb. The patient had absolutely no symptoms but those of secondary suppuration of the middle ear, with some little irritating feeling and a slightly irregular temperature. Another condition of importance is that there may be phlebitis without the formation of a thrombus. It does not follow that one is justified in operating because this peculiar typical temperature is present, no matter whether there are three or four degrees difference in 24 hours or in 12 hours. Dr. Cott's experience is that it is not necessary to open the lateral sinus unless there are other symptoms present. Less than a week before going to Portland he did a radical operation on a little girl 7 years of age, and following the operation he watched the temperature, which is still quite typical of sinus thrombosis. He did not and does not intend to operate on that child. He turned the case over to another otologist with the intention of having him operate if the child showed other distinct symptoms. She sat up and ate and felt well in every way.

Dr. C. F. Welty, San Francisco, said that the picture drawn in most cases of sinus thrombosis is so characteristic that it is downright negligence not to make a diagnosis at once. Again, the diagnosis may be so complicated that one can not say with any degree of certainty what the pathologic lesions may be. By a process of elimination the physician arrives at conclusions as to probabilities, and in most instances makes a correct diagnosis. The case that was diagnosed typhoid fever, with a temperature varying from 99 to 104 and with discharge from the ear, gives almost certain evidence of sinus thrombosis, because it is very seldom that such variations come in typhoid, and they are quite characteristic of sinus thrombosis. To make the diagnosis absolutely complete, the sinus must be uncovered and it must be incised, because the thrombus may not be complete and fluid blood may be obtained by use of the puncture needle. The physician must judge from the amount of blood that flows from the incised sinus as to the presence or absence of a thrombus. Dr. Welty has seen several cases in which the thrombus was not demonstrable by the use of the needle, but by incision it became so apparent that there was no room for doubt. It must be remembered that the patients who are operated on early are those who have the best chance for recovery, and when a physician is dealing with life-saving measures he is justified in more radical procedures. In the second case of chills and fever a diagnosis was made of malaria associated with a suppurating ear. This picture is so characteristic that a specialist should not hesitate to open the sinus if malaria has been demonstrated by microscopic examination. It was found on more careful examination, however, that the microscopist had made a mistake, and necessarily a great deal of valuable time was lost. Dr. Welty has not seen bad results follow the incision of a healthy sinus, and declared that if the operative field is surgically clean no harm has been done and the physician has eliminated a possibility that might have cost the patient's life. In this connection Dr. Welty mentioned a new operation that has been perfected by Professor Grünert of Halle. He removes the whole of the venous channel from one end of the thrombus to the other. Dr. Welty saw four such operations, and the patients all recovered.

Dr. W. H. Roberts, Pasadena, Cal., said that to those who are in the habit of waiting for the cardinal symptoms of sinus thrombosis, namely, chills, fever and sweats, before opening the sinus, the stand taken by Dr. Hastings may seem a little radical, but in cases of sinus thrombosis it is necessary to be radical. It is a mistake for physicians to wait for these cardinal symptoms, which are really symptoms of disintegration of the clot and absorption of the septic material. Operation is distinctly called for in all long-standing mastoid cases. The sinus should be thoroughly uncovered and examined carefully and, if necessary, opened, under proper precautions, to see if there is a free return of blood from both ends. By doing this physicians certainly save more cases by far than they lose.

Dr. H. Stillson, Seattle, emphasized two personal equations. The first has reference to the operator and the other has reference to the patient. It seems to him that the personal equation of the operator has not been sufficiently dwelt on. It is a very easy matter to open a mastoid, but to know what one finds is another thing. It is perhaps a comparatively easy matter to open a sinus, but to open it in a most dexterous way and recognize what one sees without undue manipulation is another question. Dr. Stillson thinks the position taken will depend largely on the skill of the operator. If he is to operate as a barber or blacksmith would, Dr. Stillson would decidedly oppose his opening the sinus. If, however, he has the skill of Dench, who may go into almost any brain with comparative safety, then let him perform the operation on these cases. The personal equation of the patient should be considered. There are patients who do not stand any operation with safety. Since this operation of opening the brain is a very important one for the patient, the surgeon should see to it that the condition of the patient is such that he will best stand the operation. There are many questions to be taken into consideration when contemplating operation in these cases.

Dr. G. A. Leland, Boston, mentioned a case which he reported in 1897 to illustrate the cause of death in these cases. It was a case of sinus thrombosis, with the classical symptoms and with a white blood count of 50,000 to the cubic millimeter. At operation the sinus was opened and the clot cleaned out as far above and below as seemed justifiable; on the eighth day the whites were found to be 10,000. A stiffness of the neck occurred on the eleventh day with very little swelling behind the sternomastoid. Suddenly a leptomeningitis developed and death occurred in two days, the fifteenth day after the operation. In this case the autopsy showed that the clot had been cleared out very well, but that there was a collection of pus below the bulb in the jugular vein. The point Dr. Leland wished to make, which may throw light on the cause of death in some of these cases, is that there was a migration of the micro-organisms with consequent infection of the sinus on the other side of the torcular herophili. The right side being the one operated on, a small antemortem adherent clot was found in the left. If this patient had not died of leptomeningitis, there might doubtless have supervened a septic phlebitis or a pyemia from disintegration of the thrombus on the other side; so that in some of these cases, unless the surgeon can cut off the head and scrape out all the sinuses, Dr. Leland does not see how he can be sure that he will not have deaths. Even though one analyzes the symptoms to the uttermost limit, he may still be unable to save some patients. Dr. Leland mentioned another hospital case in which the patient was being treated for malaria by large doses of quinin. Consultation slips were sent to the throat, the second surgical, and to the aural services because of a marked swelling on the right side of the posterior pharyngeal wall. The two former diagnosticated deep cervical abscess, and transfer to the surgical side was ordered. Briefly, the findings were as follows: A boy, medium height, slim but well nourished, had suffered several years with right purulent otitis media with almost entire obsence of drum-head; lately with suppression of discharge followed by severe headache, chills, pyemic temperature fluctuations; the left shoulder and the right knee were red, swollen and tender, evidently the result of metastases. The outside of the neck was slightly swelled on the right, but on the pharyngeal wall there was a circumscribed tumor, longest in vertical diameter, which did not fluctuate. The diagnosis was obviously sinus thrombosis with embolism and epidural abscess originating in chronic otitic suppuration with involvement of the deep cervical vein. On further consultation operation was decided on. Dr. J. C. Munro ligated the internal jugular near the clavicle, posterior to the sternocleidomastoid attachment. The respiratory blood movements were very marked. Dr. Leland then opened the mastoid process and found the sinus blue, soft, glistening, perfectly normal in appearance, but much distended. Doubt in the minds of the medical men associated in the case began to develop into adverse criticism, felt if not voiced. Yet a small collection of sero-pus—the epidural abscess—was found inside the sinus, inside and posterior to the bulb, at the base of the skull down toward the foramen magnum.

No thrombosis of the lateral sinus could be made out, even down to the bulb, but there was a thrombosis or a phlebitis of some of the communicating veins, and possibly of the inferior petrosal sinus; this morbid process later extended up into the cavernous sinus and caused exophthalmos of the right eye with some involvement of the ocular nerves, and still later even slightly affected the left eye. No further operation was necessary. The patient recovered. Mural thrombi certainly may cause even more grave and far-reaching trouble than those completely occluding the vein. So that there is a great deal to be gained by studying all these little points and making observations as accurate as possible. Special attention should be directed to the number of white blood corpuscles. An important point is the difference in the percentage of the polymorphonuclear leucocytes. If there is a high proportion of polymorphonuclear leucocytes, there is pus in the circulation.

DR. JOHN F. BARNHILL, Indianapolis, declared that in a discussion of this kind, where there enters so much of the experience-meeting character, there is a good chance for presenting the discouraging side of operative work, and the possibility, therefore, of hindering its legitimate progress, yet it must be remembered that otologists have appropriated to themselves a field of surgery that is most difficult. It is to be expected that many of our operative cases will result fatally because of their serious and otherwise incurable nature. There are so many brilliant cases of cure as the result of definitely applied surgical skill that otologists ought at least to take from it a good deal of encouragement. Later they will doubtless have much better reports to make. The point as to where these blood clots may form is worthy of emphasis. The petrosal veins may be thrombosed just as the larger veins. A thrombus may be found in the sinus extending as far as the knee, and yet such thrombus does not constitute the entire trouble. The surgeon is not always permitted to examine fatal cases after death, and, therefore, one does not always know whether he has gone far enough in the operative work. Results must depend on accurate diagnosis, and otologists should in no case fail to go to the limit of their skill in diagnostic efforts. Any aid in making a diagnosis will aid in giving better future statistics. In this connection it might also be stated that physicians are entirely too ready to attribute certain symptoms, or groups of symptoms, to malaria, rheumatism or la grippe. The otologist and rhinologist who thoroughly and skillfully investigate the condition of the open sinuses that lie adjacent to the ear and nose, and practically surround the base of the skull, will frequently find that the symptoms attributed to those diseases can be proved to be caused by sinus suppuration and absorption. The term la grippe has been so engrafted on the mind of the profession that any patient who has some chilly sensations, aching muscles and a tired feeling is said to have la grippe. By most careful investigation of cases, otologists may improve their diagnostic abilities, and through better diagnosis will most certainly result a more hopeful prognosis of lateral sinus and other intracranial ear complications.

DR. ROBERT C. MYLES, New York, said that here is a case that will probably puzzle the supreme court of the United States to determine, and there is no attorney for the defense. No one is interested in the prosecution, except the public, and they will not let physicians help them by making an autopsy. The insurance companies have probably twenty cases of brain abscess to-day where they had one ten years ago. The cases are more frequently recognized at the present time. Dr. Myles has had patients who have laid moribund for weeks with phlebitis, and they are well to-day; patients with obliterating conditions of the veins and sepsis frequently recover. It is rather common in the lower limbs to have a phlebitis from which the patient will recover. It is a question whether a blood clot that is not septic causes so much trouble. Dr. Myles is strongly in favor of operating when there is direct evidence calling for operation; but the brain should not be torn to pieces *ad libitum* on a mere suspicion or guess. His attention has been called to so many cases in which an exploratory incision of the brain has been followed by death that it is evident that surgeons should be more careful.

DR. HILL HASTINGS said that otologists should receive encouragement from the fact that it is only about 18 years since Lane, of England, cured a patient with sinus thrombosis by operation. The case mentioned by Dr. Richards is extremely interesting. The fact that he could not get an autopsy makes the diagnosis uncertain. It was one of those confusing cases that some of the best men worry over. Dr. Cott's case of extensive thrombosis shows that the "cardinal symptoms" are rather unreliable. Dr. Hastings has not seen a case like Dr. Leland's; it was a striking case and teaches much. The problem that confronts otologists in these cases is much like that of appendicitis some eight or ten years ago. A large number of the patients he has seen operated on for mastoid disease should have been operated on earlier. He thinks that is due to the reluctance of the patients and the absence of the swelling and the redness that seem to be regarded as the indications for the opening of the mastoid. When an early mastoid operation comes into vogue it is probably safe to predict that there will not be so many cases of sinus thrombosis; until then there will always be cases that may puzzle physicians a great deal. There are two classes of these cases. In one class belong those cases in which one is reasonably certain, on inspecting the sinus, whether it is thrombosed or not. That class contains the larger number of cases, but there always will be the second class of cases in which the physician will be uncertain whether or not there is a thrombus in the sinus, judging from the appearances. When the physician leaves such cases without opening the suspicious sinus he is uncertain whether he has done the best for the patient. All otologists have seen many mastoids of extensive involvement operated on, but in which the condition of the sinus was not determined, and death from pyemia follows. Many more of these cases in which thrombosis undoubtedly existed at the time of operation are not reported. Dr. Hastings, therefore, is decidedly in favor of opening the sinus in such doubtful cases. The incision should be done under proper precautions. It should be opened with a clean cut with the knife instead of using a needle for the purpose of diagnosis. In some cases sepsis has terminated in recovery without operation on the sinus; but such cases are conceded to be in the minority. He has seen several patients die from thrombosis who he is certain would have had good chances to get well if the sinus had been opened a few days earlier. Whiting has aptly stated that "the time for operation is in the first stage of sinus thrombosis" before the septic disintegration of the clot occurs; and he follows that up with the rather discouraging statement that we can not tell without operation when we have to deal with the first stage of sinus thrombosis. So we must uncover the sinus in bad cases and determine whether it is thrombosed. If in doubt, Dr. Hastings believes it is wise to open it and not to trust to luck. In reply to a question, he said that one can not expect in every case to decide by looking at the sinus; although the cases are comparatively few in which the appearance of the sinus would be as misleading as in the first case mentioned. The "feel" of the sinus, the evidence from the thickness of the wall, and the presence of purulent granulations as a rule help in the diagnosis. He does not believe that any one can tell absolutely without opening the sinus.

THE CARE OF INFANTS IN PUBLIC INSTITUTIONS.*

H. M. McCLANAHAN, M.D.
OMAHA.

It has long been recognized that the care of infants in public institutions presents peculiar difficulties. The mortality is greater among these, in any given disease, than in private practice. The reason why the institution infant has less resisting power is, no doubt, because of its impaired nutrition; and faulty nutrition is probably the result of poor food, bad air and lack of maternal care. It can not fail to have been noticed by all doing hospital work that all infections are more severe among numbers, as in a ward, than among isolated individuals.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The observations on which this paper is based were made in the Child's Saving Institution, Omaha, Neb., and covered a period of four years. This is an eleemosynary institution, supported by public-spirited citizens. It receives infants and children for care and adoption. During the years of 1902-3 the nursery was not in charge of a trained nurse. The women were kind, and did the best they could, but during the summer months of those two years the mortality was unduly large. At the close of 1903 the board of directors gave the superintendent authority to employ a trained nurse to have charge of the infants' ward. I was given absolute authority to make and enforce rules governing the care and feeding of the infants. The death rates for the years 1903-4, from preventable diseases, were very much less than for the two preceding years. This lessened death rate was due wholly, I believe, to the employment of skilled help.

My purpose in presenting this brief paper to the Section is to demonstrate the importance of prevention of disease, rather than to add anything new in the way of treatment. In this connection I wish to make a plea for greater authority for the consulting physician in the internal management of hospitals, particularly for children. He should have knowledge and control of the milk supply. He should have authority to discharge nurses when proven incompetent. The reports which follow are not nearly as complete as they should have been, or as they will be in the future.

During the year 1901, 62 infants were cared for. There were 11 deaths during the year, and of this number 10 died from diarrheal diseases during the summer months. During the year 1902 there were 106 infants cared for. There were 32 deaths in that year. Of that number 26 died during the summer months from diarrheal diseases. During the year 1903 the total number of infants cared for was 92, with 15 deaths. In this year there were no deaths in July, August or September. Almost the entire mortality was in the months of January, March, April and May. Seven deaths were due to pneumonia, four to congenital syphilis, one to purpura, one to congenital heart disease, and in the two others the cause is not given. In the year 1904, 110 babies were cared for, with 15 deaths during the year. Nine of these were due to gastrointestinal diseases, but of the nine dying from this cause eight were admitted already sick with some form of diarrhea, five of the eight dying within twenty-four hours after admission. Of the infants in the institution June 1, 1904, but one developed any intestinal trouble during the summer. I make this explanation in justice to the institution. Of the six other deaths during the year, two were due to pneumonia, two to congenital syphilis and in the other cases no cause was given. The prevention of diarrheal diseases during the past two years was due, in my opinion, to employment of skilled nurses and the rigid enforcement of certain rules which will be given later in this paper.

The infants' ward is a room 29½ feet long, 13½ feet wide, 8¾ feet high, and contains 3,482 cubic feet. As there are never less than twenty-five babies in the ward, each baby has 142 cubic feet of air space. When there are thirty babies in the ward, as is often the case, then each infant has only 110 cubic feet. As we could neither decrease the number of infants nor increase the size of the room, we have been forced to make the best of the situation, and the following expedient has been adopted: There is another ward in the building of the same size. This is used as a sleeping room for the older children. The children are removed from this room at 7 a. m., the bedding is changed, all the windows are opened, and then about 10 o'clock the infants are taken to this room. This gives an opportunity to ventilate thoroughly the infants' ward. During the summer season we have a large tent out on the lawn, open at either end, and the infants are kept here for several hours a day. Twice a week the nursery is fumigated with formaldehyd candles. The floors are wiped daily and the walls brushed down.

Another important matter with me was the care and disposal of soiled napkins, and during the last two years the following method has been adopted. Two five-gallon galvanized iron buckets, with closely fitting lids, are provided. These contain a solution composed of four ounces of common salt and two ounces of sulphate of zinc to each gallon of water. One is used for wet napkins and the other for soiled napkins. The napkins are deposited in this solution as soon as removed, and the buckets are taken to the laundry and emptied once or twice a day. The nurse is not permitted under any circumstances to leave a soiled napkin on the floor. As soon as it is removed it is taken at once and deposited in the bucket. After changing the napkin and before handling another baby or bottle, each nurse washes and then disinfects her hands in a 1 to 3,000 solution of bichlorate of mercury. This rule is rigidly enforced. I am satisfied that in an infants' ward there is more danger from this source of gastrointestinal infections than from the bottles or the milk; that is, a napkin containing the ordinary colon bacillus from a healthy child by careless handling may be the means of infecting another infant, and thereby inducing an intestinal infection.

All our infants are fed on modified milk. During the last two years we have not had a package of infant food in the house. We procure fresh milk in glass bottles, which is kept in porcelain-lined ice chests, at a temperature of 40 degrees. We also procure 20 per cent. cream. During the summer months all the food is Pasteurized. It is a standing rule that when infants receive Pasteurized food they are to receive orange juice once a day. Another rule is that one nurse prepares all the food for a given time. If there is any error, we know where to place the blame. All feeding bottles are labeled with the name of the infant. The bottles are washed with hot soapsuds once a day and then thoroughly rinsed in an alkaline solution. The nipples are thoroughly rinsed after each feeding, and are kept in a boric-acid solution.

Another rule that I have found of great value is this: An infant as soon as it is observed to be sick, whether it be a cough, a rise in temperature or offensive bowel movements, is at once isolated. In this way during the last year we have been able to prevent the spread of any contagious disease through the nursery. During the summer the head nurse is given authority to stop the milk of any baby having an offensive movement. Such an infant is given a dose of castor oil and fed on barley water until it can be examined by the physician.

DISCUSSION.

Dr. John C. Cook, Chicago, said that the education of the nurses for the care of the children is one of the most important, and, perhaps, one of the most neglected subjects in the training schools of the United States. In an institution in which he has a service, cultures from the mouths of children were made and the colon bacillus was found in so many that they stopped the nurses who were giving medicine and food from removing napkins, and ordered that a set of nurse girls take charge of the napkins and cleanse the babies. Unless one has done some bacteriologic work in this line he has no conception of the damage done babies by the unclean hands of nurses. There is no one thing that physicians as a class neglect so much as they do instruction of mothers and nurses. Not only would a large number of the bowel troubles of children be prevented, but many of the other diseases, if this instruction were carried out. Much good would be done to the general public and to the nursing babies.

Dr. Arthur W. Fairbanks, Boston, said that in his city, in a small hospital where they have a large number of the severest form of bowel infection, and formerly a number of cases of apparent reinfection, they have studied the problem and concluded that the nurses' hands have something to do with it. They have instituted a procedure of thorough cleansing of the hands of the nurses, even in changing the napkins of different children, and they have noticed since this has been put into effect a decided diminution in the reinfections. Coincident with this cleansing of the hands they have paid attention to the exclusion of flies, and the results have been most excellent. The nurses who change the napkins do not have anything directly to do with the feeding.

Dr. Alice M. Smith, Tacoma, Wash., finds that many mothers and nurses will put things into their own mouths and then transfer them to the mouths of the children; for instance, the nipple of the bottle is put into the mother's mouth and then into the child's—a most pernicious habit. The fumigation of the rooms and the washing of the floors where children are congregated can not be too much insisted on.

Dr. Kate Lindsay, Boulder, Colo., thinks that there is only one solution of the problem and that is in thorough education. She has found it impossible to get mothers to follow instruction, and her only hope is in educating a nurse and having her go from house to house where children are ill and educate the mother by doing the work before her. Nurses ought to be specially instructed for that purpose.

Dr. C. F. Wahrer, Fort Madison, Iowa, said that physicians should be almost pedantic in teaching the rules of antisepsis and cleanliness. He was recently called to attend a case of abortion in a family whose physician had died during the attendance and he was astonished to find in that isolated farmhouse that they had prepared sterilized water protected. The physician who had preceded Dr. Wahrer had done his duty well. Dr. Wahrer said that he has no sympathy with those men who claim that antiseptic measures can only be carried out in well-appointed hospitals and are impracticable in country districts. He has spent very little time in metropolitan hospitals; he has been mostly in small towns and in country practice, and he has found antisepsis quite practical wherever soap and boiling water can be obtained.

Dr. H. M. McClanahan declared that the point which impressed him in taking charge of an institution was the probability of infection of children from nurses in changing napkins, and some bacteriologic work was done by a young physician there which showed that there was no question as to the source of infection. It is well to remember that there are other sources of infection than that of impure milk. The thorough ventilation of the rooms which was systematically carried out he feels was very important. They did not use any of the patent milk foods and found no necessity for them. Sometimes in children from two days to six weeks of age it was found that the simple whey mixtures, with the addition of cream, were preferable to modified milk.

English as She Is Wrote.—The liberties taken with rhetoric under the banner of science are a source of never ending amazement. This license is particularly glaring in the splitting up of sentences. It appears to be assumed that a succession of adjectives and nouns without prepositions, conjunctions or verbs, is sufficient to convey an idea, and that the precious time of physicians need not be wasted in the reading of a complete sentence. Instances of this are so numerous, especially in reports of cases, that illustrations are not needed. Punctuation is fast becoming a lost art.—*Albany Medical Annals.*

A FOURTH DETAILED REPORT OF THE SUPERIOR AND LASTING RESULTS OF MY BI-INGUINAL OPERATION FOR SIMPLE AND COMPLICATED ASEPTIC RETROVERSION OF THE UTERUS.[*]

A. GOLDSPOHN, M.S., M.D.
Professor of Gynecology Post-Graduate Medical School, Senior Surgeon and Gynecologist to the Evangelical Deaconess Hospital and Attending Gynecologist to the Post-Graduate and Charity Hospitals.
CHICAGO.

Since Professor Kossmann[1] of Berlin has designated this operation by my name in a paper before the Berlin Medical Society, I may be excused for naming it so also, although I have so far applied to it its anatomic name only, notwithstanding that the combination of an extended Alexander operation, with bi-inguinal celiotomy and the Bassini hernia technic in closing the wounds with anchorage of the round ligaments to Poupart's ligaments, was made by me completely and solely in 1893, and performed in at least 75 cases, of which 47 were published, before I learned that any one else also was doing it.

This operation owes its origin and persistent growth, in the face of much opposition, to the mandates of several stern anatomic facts: (1) The round ligaments of the uterus are the only structures connected with it that, as a part of it, are composed sufficiently of nonstriated muscular fibers to undergo growth with it during gestation, and involution also after labor. Striated muscle, no matter from where it is brought, can not be expected to do that; and certainly no other soft tissues will do anything of this kind, but will stretch, at best, during gestation and frequently without this, and will remain long and useless.

(2) The round ligaments of the uterus taper from within outward, so much so that their uterine origins are at least six times as strong as they are at their extraperitoneal, but intra-abdominal portions, which compose their most vulnerable parts.

(3) These weak parts that call for reinforcement or elimination, however, are readily accessible only via the inguinal canals from without, and not advantageously by any vaginal or ventral incision. Accordingly, the operations which shorten the ligaments by these routes, especially those of the Mann, Ries,[2] and Webster[3]-Baldy[4] types, are anatomically wrong, because they shorten them by doubling up their thick, accessible ends and leave the outer feeble and inaccessible portions as weak and liable to stretch as before. Far preferable to these are a numerous class of intramural transplantations of the round ligaments, most of them proceedures advocated during recent years, respectively, by Ferguson,[5] Gilliam,[6] G. H. Nobel,[7] H. T. Byford,[8] F. F. Simpson,[9] E. E. Montgomery,[10] McGannon,[11] Sperling[12]

---

and C. H. Barrett.[13] In these commendable operations the round ligaments are separated intra-abdominally from the broad ligaments to a sufficient extent and are then drawn into the median ventral incision or into stab wounds near it and fastened, or with a suitable curved and slender forceps they are passed subperitoneally forward and around the bladder to the internal abdominal rings and stitched fast there to the muscular part of the abdominal wall. Or they are drawn, with a similar forceps, beneath the peritoneum or between muscular layers at or near the internal rings and from there into the median ventral incision or into the ends of a transverse fascial (Pfannenstiel) incision, and fastened there. All these kindred methods of transplanting the round ligaments into the abdominal wall are anatomically consistent: (1) Because they discard the useless outer portions of the round ligaments and place their inner strong portions to do the work, either of suspending the uterus or holding it forward, or partly both, and (2) because all of them, except the Ferguson and Gilliam methods, avoid making transperitoneal bands or bridges.

During the last several years I have treated more patients by one of these methods than by my own operation, for the following reasons: (1) Simple, movable retroversions with healthy appendages are, by me, *largely treated* by pessaries with regular monthly or bimonthly revision and adjustment; (2) in the complicated cases the majority of the patients either have active infectious elements, or strong suspicions of such, still remaining, so that they demand preferably a median ventral section with sight to supplement touch (which I have always chosen for this class); or they have some other disorder like a chronic appendicitis, a widened linea alba, or a ventral hernia that should be eliminated also, or an incidental palpation of a supicious kidney, gall bladder, stomach or bile ducts, determines the choice of a ventral incision; (3) during the very systematic and searching reviews in which my surgically treated patients with retroversion together with the results of pelvic peritonitis have been afterward studied by me to find out the real merits and demerits of my bi-inguinal work, during the last ten years, I have learned incidentally that in the cases of marked general pelvic peritonitis with bilateral salpingo-oöphoritis the infectious elements will frequently die out or become innocent; but quite firm and general adhesions of the uterus and particularly of the adnexæ remain, with follicular, cystic, or sclerotic ovaries and closed and deformed tubes. By liberation of all adhesions, by removing the worst parts of the adnexæ and reconstructing the remainder, chiefly by salpingostomy and resection of ovaries and by securing for the uterus a favorable position and also a better condition by an effective curettement and amputation of a pathologic cervix, when needed, these patients, with few exceptions, can be made well, with or without a subsequent course of general medical treatment, combined sometimes with local massage and a galvanic current, as, for instance, for an old metritis—but they rarely become pregnant.

Before I knew this I treated this class of patients mostly by my own operation, in view of the supposed capacity for conception that they might retain. The Alexander operation is pre-eminently the one to be chosen for fruitful women: and the urgency of its indication is directly proportionate to the reproductive capacity of the patient. This operation stands in the vanguard, practically without a competitor, in the vast amount of anatomic and clinical evidence which it has furnished that it not merely supplies to the uterus favorable conditions for conception and increases its productive capacity, but that it is also able to cope with its critical metamorphoses during parturition and the period of involution. But when this highest function of the uterus has been lost, some one of the above-mentioned methods of utilizing the thick ends of the round ligaments through a ventral incision is good enough to correct the displacement and better for the other indications.

It is the prevailing sterility among this class of patients who are otherwise restored to fair or perfect health by conservative surgery, that induces me not to continue to treat them via the dilated inguinal rings. The surgical indications in these cases of retrodisplacement with adhesions and deformed appendages can be very safely and successfully, although not so conveniently, carried out in that manner, provided that active infectious elements are found no longer present by repeated, careful bimanual examination with properly educated fingers. That this is true I have demonstrated on at least one hundred of such patients with adhesions and other marked complications in the adnexæ who were treated by that method with a mortality rate of 1.5 per cent., with no hernia following, with at least 99 per cent. of anatomic cures (of position of the organs) and 87 per cent. of subjective cures, aside from the predominating sterility. The objection which some men raise to the matter of separating adhesions of the uterus and adnexæ without sight is hardly valid, nor well taken, because these same adhesions in such cases they themselves would liberate usually through a ventral incision of two or three inches, which would usually preclude sight of the adhesions deep down in the small pelvis beneath and around a retroverted uterus. Only after the adhesions have been severed and the parts have been separated is sight really admitted, to assist in repairing some possible damage, it is true, but scarcely to prevent it.

While I *concede that the additional* care, labor and inconvenience of bi-inguinal celiotomy are misplaced when offered up in patients with displacement of the uterus who retain *merely* a nominal reproductive capacity, or none at all—because they will never be in a position *to realize its superior* benefits—I must, however, contend more earnestly than ever, that bi-inguinal celiotomy, *on account of its completeness* and thoroughness, should be made to supplant the old *superficial*, extraperitoneal Alexander *operation* in all cases, at least to the extent of a careful and intelligent digital exploration of the uterus and adnexæ through both inguinal rings, *in order that* certain peculiar conditions and otherwise undiscoverable complications like the following *may be successfully dealt* with, even in the seemingly simple cases:

First: Adhesions of the ovary and abdominal end of the tube are of much more *frequent occurrence* than of the uterus itself, because, in their vicinity, infections *enter the* peritoneal cavity first through its most frequent channel, the endometrium, and the tubes. Adhesions of these small structures are very difficult to discover and are often not suspected *when the uterus* is free and reducible. They were formed on these adnexæ in their descended position, to which they sank in consequence of the retroversion *of the uterus*. When the uterus is brought into anteversion these, its wings,

---

[13] Barrett, C. W.: Proc. Chicago Med. Soc., June 21, 1905.

Patient.	Symptoms.	Anatomical Diagnosis at operation.	Additional to bi-inguinal section and date.	Result and convalescence.	Postoperative condition.
1. Mrs. D. F., aged 34 years; iv-para and two abortions; housewife.	Extremely nervous and anemic; menorrhagia and dysmenorrhea; very dyspeptic diffuse pelvic pains.	Extreme retroversion, movable, descended adherent left ovary; cervix with deep laceration and ulceration, with many Naboth follicles.	Curettement; amputation of cervix; resection of both ovaries. Jan. 11. 1902.	Patient died 27 hours after operation, of cerebral embolism.	Left round ligament was traced from the broad ligament outward. Both round ligaments very small; for twenty-six hours after operation patient's condition was very satisfactory, pulse of from 68 to 100, and temperature from 99.2 to 101.2 by rectum; general condition very good, aside from nervousness. Patient suddenly became cyanosed: failure of respiration and death followed within twenty minutes.
2. Mrs. A. R. C., aged 34; multipara; conductor's wife.	Constant pain in left ovary. backache; much headache. almost unable to walk.	Movable retroversion, metritis, endometritis; pathologic cervix; lacerated perineum, prolapse of left ovary and of vaginal walls.	Curettement; amputated cervix; perineorrhaphy; resection of both ovaries. Feb. 1, 1902.	Almost afebrile, course. primary union of inguinal wounds.	Examination June 5, 1905. (Dr. R. L. James). Uterus was anteverted, but sacrouterine ligaments elongated, permitting cervix to slide down, thus taxing round ligaments above. Patient is very corpulent, and has slight descensus of vaginal wall, but is quite well.
3. Mrs. W. B. B., aged 21; 0-para; mechanic's wife.	Anemic; very nervous and hysterical; much heart palpitation, and dyspnea, dysmenorrhea and neurasthenia; marked languor and backache.	Mobile, extremely retroverted uterus; catarrhal cervix, descended left ovary with numerous large follicle cysts.	Curettement, resection left ovary, exploratory incision and suture of right ovary. Feb. 3, 1902.	Afebrile, very comfortable course: complete primary union.	Examination, May 12, 1905. Patient was feeble and nervous for a year after operation, then she became pregnant; normal birth of large child a year ago, with puerperal fever five weeks. Position and condition of organs are now ideal, aside from a little cervical catarrh and occasional backache; nurses big baby and does housework.
4. Mrs. C. S., aged 31, iv-para; laborer's wife.	Fairly nourished but anemic, severe general pains and backache; headache: dyspnea and precordial distress.	Severely pathologic cervix, with adenoma of anterior lip; very large metritic uterus, in extreme but mobile retroversion; descended cystic very tender left ovary; lacerated perineum.	Curettement; high amputation of cervix; intrapelvic, infravaginal perineorrhaphy; resection of one ovary. Feb 10, 1902.	Twelve hours after operation patient very restless almost maniacal, with pulse 106, temp. 103; afterward normal; primary union.	Examination, June 9, 1905. Position of appendages and uterus perfectly normal. Former disabilities all gone, works regularly as scrubwoman, says "I am real well."
5. Mrs. H. B., aged 32; seamstress; widow.	Back and side aches and severe dysmenorrhea.	Extreme retroversio-flexion, fixed by cohesion; endometritis, and descended cystic left ovary.	Curettement, resection of left ovary. Feb. 4, 1902.	Smooth convalescence. primary union.	Report by intimate friend that patient moved away six months ago, was then, and is now, in very good health.
6. Mrs. E. M. W., aged 43, multipara; saloon-keeper's wife.	Constant pains in side and back, headaches; palpitation; intercostal neuralgia; excessive and painful menses.	Metritic, retroverted mobile uterus, severely pathologic cervix lacerated and relaxed pelvic floor and perineum. double femoral hernia; right floating kidney; hemorrhoids.	Curettement, amputation of cervix; perineorrhaphy; 3 hemorrhoids removed by cautery; radical operation for bilateral femoral (omental) hernia, in conjunction with the bi-inguinal operation. March 1, 1902.	Complete primary union: very prompt recovery.	Examination, June 7, 1905. Perfect position and condition of all organs, normal and painless menses: good, robust health, and thinks examination hardly needed.
7. Miss M. W., aged 21; virgin; farmer's daughter.	Disabling severe dysmenorrhea; constant backache; leucorrhea; dyspepsia.	Mobile retroversion and endometritis; close cervical canal; cystic right ovary; very slender right ligaments.	Curettement, resection of right ovary; left round ligament traced from broad ligament outward. March 1, 1902.	Complete primary union; nearly afebrile course.	Examination, June 3, 1905. Married, normal gestation ended six months ago; uterus now in ideal anteversion, and good involution. She has no pelvic or other symptoms aside from profuse menses without pain. She is in good vigorous health and nurses baby.
8. Miss A. P., aged 26, domestic, single, 1-para.	Disabling pain in right side of pelvis and groin; right intercostal neuralgia, backache, leucorrhea, dyspepsia, constipation.	Anteflexed but retroverted and retracted mobile uterus; endometritis, erosion of os; right tube much enlarged, and occluded by ovary with follicle cysts, both markedly adherent.	Curettement, resection of left ovary, removal of right adherent tubo-ovarian conglomerate. March 25, 1902.	Primary union: normal convalescence aside from temperature 102, for a few days.	Examination, May 11, 1905. Anatomic and functional status is normal: no complaint, aside from sterility so far; has been married two years.
9. Miss M. W., aged 16½, domestic; virgin; very large girl; menses at 12 years.	Constant disabling left-sided pain and backache; leucorrhea. menorrhagia and metrorrhagia.	Anteflexed but retroverted and retroponated uterus; catarrhal cervix; left ovary large with follicle cysts.	Curettement, resection of both ovaries; late superficial suppuration of one wound; severe ether (inhalation) bronchitis, with pulse 130, temperature 102.5, respiration 30, as maximum for three days' pain in chest.	Convalescence prolonged by burns of legs from hot water bags.	Examination, May 23. 1905. Normal position of all organs. Was well until a year ago; catarrhal endometritis evidently since then, with excessive and painful menses. She is working regularly as domestic, has severe nasopharyngeal catarrh.
10. Mrs. C. W.; v-para; laborer's wife.	Anemic, poorly nourished woman; constant pain right side and back; dyspeptic, very nervous, dysmenorrhea.	Metritic retroverted uterus: mobile pathologic cervix: both ovaries adherent; right one cystic; right kidney descended.	Curettement, amputation of cervix; removal of right ovary and tube; resection of left ovary. April 14, 1902.	Comfortable convalescence: complete primary union.	Examination, June 15, 1905. Uterus and ovary in excellent position. She is in normal condition also until recent gonorrheal (?) infection. She now has endometritis, and pain in ovary, but does washing and housework.
11. Mrs. N. O. H., aged 39; iv-para and 6 abortions; tailor's wife.	Large, flabby, anemic woman, poorly nourished: intense backache, dysmenorrhea, dyspepsia, nervousness and headaches.	Metritic, retroverted, adherent uterus; ovaries both cystic and adherent; lacerated perineum.	Curettement, perineorrhaphy: removal of right ovary, resection of left ovary. May 1, 1902.	Very smooth convalescence and primary union complete.	Examination, Sept. 10, 1904. Position and condition of uterus good; now in good health. During the first eight months tincture of iodin was applied to endometrium several times, and galvanic current to ovary more frequently; medical treatment, for renal insufficiency and rheumatism.

12. Mrs. T. S. M. aged 32; I-para housewife.	*Intense pain in back and left side; dysmenorrhea, dyspepsia, constipation.*	Uterus broadly adherent; severe endometritis; firm adhesions of both tubes and ovaries, the former closed.	*Curettement; freeing adhesions* throughout; resection of both ovaries; right salpingostomy. May 20, 1902.	Primary union; normal convalescence.	Examination, June 13, 1905. Position and condition of all organs normal, aside from some tenderness of fundus. She has backache sometimes; menses normal; she does housework. Sterile so far.
13. Miss M. B., aged 25; virgin seamstress.	Right-sided pain constantly; severe disabling dysmenorrhea, during entire period; leucorrhea since puberty.	Anteflexed retroverted and descended metritic uterus, mobile; patulous cervical canal; cirrhotic right and cystic left ovary prolapsed.	Curettement; little resection of left ovary; extensive resection of right ovary. May 24, 1902.	Primary union; normal convalescence.	Examination, May 15, 1905. Anatomic condition and position of organs good, but has tenderness of right ovary; former disabling backache, etc., all gone. She has worked almost constantly as seamstress during the last two years.
14. Mrs. R. D. L. aged 21; 0-para one abortion; *office attendant.*	Large robust woman, constant disabling pain in left hip and side; dysmenorrhea and menorrhagia; dyspepsia and extreme nervousness.	Large retroverted mobile uterus; endometritis; left large cystic ovary badly descended.	Curettement, resection and suspension of left ovary. June 4, 1902.	Primary union; nearly afebrile and comfortable convalescence.	Examination, Dec. 15, 1904. Uterus and appendages in good position and fair condition. She has required medical treatment for rheumatism, and at times local galvanism to left ovary for a year, otherwise she is *robust and an efficient office manager.*
15. Mrs. W. T., aged 30; 0-para, one abortion; tailor's wife.	Strong plethoric woman; constant back and left-side ache, dysmenorrhea; sterility chief complaint.	Metritic uterus, in adherent retroversion; large left cystic ovary; descended and adherent, relaxed perineum.	Curettement; perineorrhaphy; resection of left ovary; July 26, 1902.	Smooth convalescence; primary union throughout.	Examination, May 12, 1905. Had good health directly after operation; became pregnant in nine months; normal gestation and labor, normal condition and position of organs two months later; she is now pregnant again six months and in "too good health."
16. Miss A. C. W. aged 30; virgin bookkeeper.	Constant right-sided pain; backache, dyspepsia, severe dysmenorrhea.	Large uterus, in marked retroversion, flexion, mobile; endometritis; descended left ovary; floating right kidney.	Right nephrorrhaphy; curettement; resection of both ovaries; Aug. 4, 1902.	Nearly afebrile, quite comfortable course; complete primary union of wounds.	Examination, June 18, 1904. Uterus anteverted, but also anteponated, from relaxation of sacrouterine ligaments in normal condition. Right ovary now quite painless, after six months' treatment by galvanism; she has some dysmenorrhea, otherwise is well and holds important office position.
17. Mrs. W. H. R. aged 25; I-para; housewife.	Flabby adipose woman, marked dysmenorrhea; constant backache, right-sided pain; dyspepsia and palpitation.	Extreme retroversion; uterus mobile, endometritis; ovaries descended; right one large with follicle cysts; relaxed pelvic floor.	Curettement; perineorrhaphy, resection of right ovary. Aug. 15, 1902.	Complete primary union; normal course.	Examination (Dr. Barnard), May 22, 1905. Normal position and condition of all organs; painless menses; perfectly well, and does full domestic duty.
18. Miss R. G., aged 21; virgin nurse.	Persistent left ovary pain; backache; dyspepsia, dysmenorrhea, menorrhagia, constipation.	Mobile retroversion; fungoid endometritis; cystic left ovary.	Curettement; resection of left ovary. Aug. 15, 1902.	Complete primary union; afebrile, comfortable convalescence.	Examination, June 26, 1905. Position and condition of organs ideally good; menses painless; no pelvic symptoms; robust health, great gain in weight; married two and a half years.
19. Miss M. N., aged 28; virgin; farmer's daughter.	Constant left-sided pain; extremely severe dysmenorrhea, with hysterical paroxysms.	Extreme retroflexion; uterus mobile; large descended, tender left ovary; right ovary less so; long, hard catarrhal cervix; endometritis.	Curettement; internal os constricted, wide dilatation of same; resection of ovaries. Sept. 25, 1902.	Almost afebrile, comfortable course; primary union.	Examination, Sept. 19, 1903. Fundus uteri well to front, but cervix too far anteriorly, owing to too much elongation of sacro-uterine ligaments; she also has marked bearing down discomfort still; right ovary cystic; now ventral section, *and removal of right ovary and tube,* and appendix, round ligaments, suspension of uterus.
20. Mrs. F. M., aged 37; II-para, one abortion; musician's wife.	Anemic, poorly nourished, woman; constant left-sided pain; marked dysmenorrhea; backache, leucorrhea, dyspepsia.	Retroverted, adherent uterus, endometritis, indurated surface after former trachelorrhaphy; cystic and cirrhotic ovaries; buried in adhesions; lacerated perineum. (Dr. Zinke thought he would have removed left ovary.) Sept. 25, 1902.	Curettement; perineorrhaphy; liberating of all parts; suspension of right ovary and tube; resection of left ovary.	Nearly afebrile course; primary union.	Examination, June 15, 1905. Normal position and condition of uterus, tenderness and occasional pain from ovaries; she does all her housework.
21. Mrs. F. K., *aged 36; II-para, one* abortion; housewife.	Nervous, emaciated woman; *constant left-sided pain,* general pelvic aches; menorrhagia and gastric pain.	Large metritic uterus, retroverted, *mobile; pathologic* cervix; endometritis; adherent right ovary and tube.	Curettement, amputation of cervix, liberation and resection of right ovary; removal of left tube and ovary by electric thermocautery. Sept. 29, 1902.	Some temperature; much *nervous disturbance;* primary union.	Examination, Nov. 1, 1903. Normal position of uterus and ovary; has required several strong intrauterine iodin cauterizations for recurring hemorrhagic endometritis; good position of organs, but complains still of backache, dysmenorrhea, and thoracic neuralgia; she is a pronounced neurasthenic.
22. Mrs. H. W. H. aged 30; multipara; working housewife.	Well-nourished, strong woman, severe and constant leucorrhea; constant left-sided pain.	Mobile retroversion, with endometritis; pathologic cervix; painful left ovary; lacerated perineum.	Curettement, amputation of cervix; perineorrhaphy; resection of left ovary. Oct. 2, 1902.	Complete primary union; catheter required for ten days and bladder irrigation afterward.	Examination, June 12, 1905. Perfect position and condition of uterus and adnexa; menses normal, painless; has no pelvic nor other symptoms; gained 20 pounds. Robust health.
23. Miss C. S., aged 36; virgin; dressmaker.	Anemic, very nervous woman; intense backache, constant left-sided pain, dysmenorrhea, dyspepsia.	Extreme retroversion; uterus mobile, with severe catarrhal endometritis; descended, very tender ovaries, cystic and cirrhotic; catarrhal left tube.	Curettement; resection of right ovary; removal of left tube and ovary. Oct. 25, 1902. Bad ether narcosis.	Moderate temperature for several days; primary union but induration of wound.	Examination, June 20, 1904. Position of uterus and ovary very good, but chronic metritis continues; has bearing-down sensations; has digestive disorder, headaches, dysmenorrhea and marked neurasthenia; half capacity as dressmaker.
24. Mrs. A. K., aged 28; widow.	Fairly nourished woman, vigorous frame, backache, dysmenorrhea, menorrhagia.	Mobile retroversion, with endometritis; lacerated perineum; adnexa descended but normal.	Curettement; perineorrhaphy; intraperitoneal palpation of adnexa. Oct. 31, 1902.	Comfortable convalescence; primary union complete.	Examination, October, 1904. Dr. Barnard. Uterus in good position, but patient is pregnant and bleeding from an induced abortion. In good health until now.
25. Mrs. M. M., aged 31; IV-para; working housewife.	Anemic, poorly nourished woman; somewhat neurasthenic; constant right sided pain and backache; leucorrhea, dyspepsia and melancholia.	Extreme retroversion, of subinvoluted uterus; free, endometritis; right ovary very large and partly cirrhotic.	Curettement; resection of right ovary. Nov. 10, 1902.	Little temperature for two days; patient comfortable and cheerful; primary union.	Examination, May 30, 1905. Normal position and condition of all organs, aside from endometritis, since an induced abortion; is in greatly improved spirits since operation; feels well; has full working capacity.

Patient.	Symptoms.	Anatomical Diagnosis at operation.	Additional to bi-inguinal section and date.	Result and convalescence.	Postoperative condition.
26. Mrs. B. W., aged 25; multipara; working housewife.	Slender frame, anemic, very nervous: constant back and side aches, with bearing down feeling; left intercostal neuralgia, dyspepsia, diarrhea, palpitation.	Extreme retroflexion; uterus movable; endometritis, subinvolution; lacerated perineum; ovaries partly cystic and cirrhotic.	Curettement; perineorrhaphy resection of both ovaries Nov. 12, 1902.	Almost afebrile course anxious for solid food primary union.	Examination, December, 1903. In good health during last half year; was nervous and feeble for six months; had one application tincture iodin to endometrium for excessive menses; also general medical treatment; organs now in good position and condition.
27. Miss A. Z., aged 22; virgin; schoolgirl.	Slender build, anemic, nervous; constant backache and right-sided pain; dyspepsia. severe disabling dysmenorrhea.	Extreme retroversio-flexion uterus mobile; large corpus luteum; cyst in adherent right ovary; sclerosed left ovary; two small parovarian cysts in tubal left mesentery.	Curettement; liberating and resection of right ovary; removal of left parovarian cysts. Nov. 20, 1902.	Afebrile, comfortable convalescence; primary union.	Examination, May 8, 1905. Anatomic status and function of all organs fully normal; former irregular menses now regular every 26 days; formerly dysmenorrhea (cramps), now no pains with menses; formerly constipation, now regular bowels, appetite good, no dyspepsia; occasional rheumatism; works regularly.
28. Mrs. C. H., aged 26; i-para; working housewife.	Slender, fairly nourished woman; constant side and back ache; dysmenorrhea, menorrhagia.	Moderate retroversion of subinvoluted uterus; endometritis; ovaries partly cirrhotic, partly cystic.	Curettement; resection of both ovaries. Dec. 15, 1902.	Afebrile, comfortable convalescence; complete primary union.	Examination, May 10, 1905. Normal position of all parts; entirely well until a few months ago; now uterus and left ovary a little tender; slight dysmenorrhea and leucorrhea; does full housework.
29. Miss D. B., aged 22; virgin; domestic.	Slender, anemic, poorly nourished woman; constant left sided pain and backache: leucorrhea; dysmenorrhea: dyspepsia, suspicions of stones in bile passages.	Extreme retroversion; movable uterus; large right femoral ring; endometritis descensus of left cystic ovary.	Curettement, resection and suspension of left ovary ligaments slender and fixed in broad ligaments, requiring careful dissection to develop them. Nov. 25, 1902	Normal recovery; late suppuration on one side.	Examination, Aug. 19, 1904. Position of uterus and ovaries normal, the latter are tender, some dysmenorrhea and diffuse pelvic pains. The patient is anemic, poorly nourished, hysterical and has dyspepsia and more marked disorder of bile passages; only half working capacity.
30. Mrs. J. W., aged 29; 0-para; sterile; housewife.	Vigorous frame, well nourished; severe dysmenorrhea. constant pain in back and left side.	Retroverted, mobile uterus, left ovary and tube extremely adherent; right tube and ovary less so, and cystic; fistula in ano.	Curettement; operation for fistula in ano; difficult but complete liberation of left tube and ovary, also of right adnexa; resection of both ovaries, suspension of left tube and ovary; right salpingostomy. Jan. 8, 1903.	Little temperature; very comfortable convalescence and primary union	Examination, May 18, 1905. Perfectly normal position and condition of all organs in pelvis; menses normal and painless; no symptoms but sterility; robust health.
31. Mrs. H. Y., aged 24; iii para, two abortions; housewife.	Anemic, fairly nourished woman; constant backache and left-sided pain; dyspepsia, constipation.	Metritic retroverted mobile uterus; both ovaries enlarged; right ovary adherent; endometritis.	Curettement; removal of left tube and ovary; liberation and resection of right ovary	Comfortable primary union	Examination. Patient became pregnant after nine months; gestation normal and comfortable, aside from little pain in left scar; labor fourteen hours; normal; child 11½ pounds. Examined March 22, 1905. Position and condition of all pelvic organs normal; robust general health (Dr. Bernard).
32. Miss L. S., aged 39; virgin, nurse.	Fairly nourished; constant left-sided pain and back ache; severe dyspepsia; dysmenorrhea and menorrhagia.	Mobile retroversion and endometritis; very large cystic left ovary, extremely descended; right ovary less so.	Curettement; removal of left tube and ovary and resection and suspension of right ovary. appendectomy with electrothermic forceps through small separate wound, made bluntly, appendix buried behind cecum April 2, 1903.	Primary union and normal course aside from intestinal obstruction for which appendiceal wound was opened and small intestine liberated 30 hours after operation.	Examination, May 22, 1905. Position and condition of uterus and ovary normal; little backache and headache at menstrual time; flow two days; good general health.
33. Mrs. J. A. W., aged 27; 0-para; housewife.	Fairly nourished, severe left-sided pain and backache: dyspepsia and headache: dysmenorrhea; very nervous.	Mobile retroversion and metritis; globular extremely descended left ovary; both ovaries contained follicle cysts.	Curettement; resection of both ovaries: reinforcement of round ligaments with peritoneal envelope. April 9 1903.	Primary union; very comfortable convalescence.	Examination, June 1, 1905. Position and condition of uterus and appendages ideal; no symptoms anywhere except sterility; marked gain in flesh.
34. Mrs. B. K., aged 24; 0-para; working housewife.	Well-nourished woman; severe pain in back and right side; dysmenorrhea; gastralgia and headaches.	Uterus retroverted and firmly adherent; ovaries likewise; marked endometritis; cystic ovaries.	Curettement; liberation of uterus and adnexa; resection of both ovaries; extensive dissection of round ligaments out of broad ligaments. May 25, 1903.	Temperature 102.5 on second day, quickly subsided; fairly comfortable convalescence; ligature abscess on right side after second week.	Examination, May 10, 1905. Condition and position of pelvic organs normal; some backache at menses; sterility only complained of; does full housework.
35. Mrs. T. A. L., aged 21; 0-para; housewife.	Strong, well-nourished woman; constant right-sided pain and backache; painful and irregular menses; headaches.	Retroverted uterus; left tube and ovary firmly adherent; severe endometritis; left hydrosalpinx size of finger; both ovaries cystic.	Curettement; resection of right ovary; removal of left ovary and hydrosalpinx. July 17, 1903.	Afebrile, primary union; sat up in one week.	Examination, Jan. 30, 1904 (Dr. James). Position and condition of pelvic organs very good.
36. Miss I. F., aged 23; virgin; clerk.	Somewhat anemic woman; constant left-sided pain; backache, dyspepsia, constipation, headache, irregular painful menses.	Uterus retroverted and anteflexed, movable; stenosis of cervical canal and internal os; left ovary corpus luteum cyst.	Difficult dilatation and curettement: slight incisions within internal os, cauterized. resection of left ovary; difficult dissection of distal portion of right ligaments. July 20, 1903.	Afebrile, primary union.	Examination, June 4, 1905. Perfectly normal position and condition of pelvic organs; no symptoms; menses now regular, three days and painless; no leucorrhea.
37. Mrs. H. B., aged 22; 0-para; manicurist.	Slender, fairly nourished woman; constant left-sided pain from ovary; severe dysmenorrhea.	Mobile retroversion; descensus of cystic left ovary; left inguinal hernia.	Curettement, resection of left ovary; radical cure of left inguinal hernia. Sept. 21, 1903.	Very smooth and afebrile; complete primary union.	Examination, June 12, 1905. Perfectly normal position and condition of uterus and adnexa; menses painless; no pelvic or other symptoms; is in good health and works regularly.

38. Mrs. D. W., 0-para; working housewife.	Poorly nourished, anemic woman; constant pelvic pains; dyspepsia, gastralgia, extreme nervousness.	Mobile retroversion and endometritis; firmly adherent adnexa; cystic and cirrhotic ovaries; closure of both tubes, left one a hydrosalpinx.	Curettement; freeing of adnexa; resection of right ovary; opening right tube; suspension of both; removal of left hydrosalpinx and left ovary. Sept. 25, 1903.	Temperature 101 for three days; complete primary union; very nervous.	Examination, May 21, 1905. Patient was nervous; had various pains during first six months; received general medical treatment; uterus and ovary in good position and fair condition; great gain in weight; normal working capacity, but bemoans sterility.
39. Miss A. K., aged 30; virgin; cashier.	Stout, well-nourished woman; constant side and back aches; dyspepsia.	Mobile retroversion; catarrhal uterus; cystic left ovary.	Curettement; formalin cauterization; stitching wound of corpus luteum cyst. Sept. 28, 1903.	Afebrile, comfortable; primary union; unusual amount of uterine discharge from cauterization.	Examination, Dec. 24, 1904. Position and condition of uterus normal; right ovary tender and often source of pain; she had amenorrhea five months after operation, with discomfort; in very good health otherwise since marriage six months ago.
40. Miss A. C. V., aged 20 virgin; stenographer.	Fairly nourished woman; constant left-sided pain; severe dysmenorrhea; dyspepsia.	Movable retroversion; cystic descended left ovary; catarrhal uterus.	Curettement; resection of left ovary; removal of hydatid cyst from right tube. Nov. 9, 1903.	Very comfortable, afebrile course; primary union.	Examination, May 13, 1905. Position and condition of pelvic organs normal; menses regular and painless; little leucorrhea; good health; works regularly.
41. Mrs. O. B., aged 22; II-para; working housewife.	Anemic, poorly nourished woman; diffuse pelvic pains, worse on right side; dyspepsia, headaches, nervousness.	Mobile retroversion and endometritis; large and follicular ovaries; lacerated perineum.	Curettement; resection of both ovaries; perineorrhaphy. Jan. 4, 1904.	Smooth afebrile; primary union.	Examination, Oct. 10, 1904. Position of uterus and ovaries normal; excessive menstrual flow; leucorrhea; otherwise well; intrauterine iodin application with syringe applicator.
42. Mrs. S. H., aged 35; III-para; working housewife.	Fairly nourished woman; little anemic; constant backache and dyspepsia; dysmenorrhea.	Uterus extremely retroverted metritic, movable; lacerated perineum.	Curettement; perineorrhaphy. Jan. 7, 1904.	Afebrile; primary union; catheter required one week.	Examination, March 15, 1905. Normal position and condition of adnexa; after four months' medical treatment for rheumatic conditions and local treatment of metritic uterus by massage and galvanism, she has quite good health and strength.
43. Mrs. W. P., aged 23; 0-para; married five years; housewife.	Well-built and nourished woman; constant right-sided pain and backache; dysmenorrhea and menorrhagia.	Retroverted, metritic movable uterus; adnexa both sides adherent; left ovary cystic, right hydrosalpinx.	Curettement; liberation of adnexa; removal of right tube and ovary. Jan. 30, 1904.	Normal; primary union.	Examination, May 23, 1905 (Dr. White). Condition and position of pelvic organs normal; menses normal, painless; normal general health.
44. Mrs. J. L., aged 32; III-para; working housewife.	Patient with rugged muscular frame, constant backache; dyspepsia and great nervousness; obstinate neuralgias in chest and head; menorrhagia.	Metritic movable uterus in marked retroversion; severely pathologic cervix lacerated perineum. Right ovary cystic (corp. luteum).	Curettement, amputation of cervix; perineorrhaphy; resection of right ovary; removal of three hemorrhoids by ligatures. Feb. 4, 1904.	Smooth; primary union.	Examination, Sept. 3, 1904. Position of uterus and adnexa very good and in fair condition, but has required massage and galvanism of uterus for continued metritis for about four months. Patient has renal insufficiency, with some dysmenorrhea and rheumatism.
45. Mrs. W. A. L., aged 31; 0-para; housewife.	Fairly built and nourished woman; melancholic disposition, extreme nervousness, disturbed sleep; pelvic pains not prominent; dysmenorrhea.	Extreme retroversion; uterus mobile, large; ovaries descended and cystic.	Curettement; resection of both ovaries (at patient's house). Feb. 18, 1904.	Some febrile movement stitchhole abscess on one side; almost total intestinal obstruction for two days resolved spontaneously	Examination, Feb. 7, 1905. Uterus rather large in fair not marked anteversion; menses normal; local massage and galvanism of metritic uterus for several months after operation and tonics for a longer time; has gloomy moods still at times, but no pelvic symptoms.
46. Mrs. F. S., aged 37; IV-para and 2 abortions; minister's wife.	Anemic woman; melancholia with maniacal paroxysms; dysmenorrhea; constant backache; intercostal neuralgias; dyspepsia.	Mobile retroversion; marked metritis; lacerated perineum; cystic right ovary.	Curettement; perineorrhaphy: resection of ovary; right ligaments thin and soft; left ligament tore off but stump was caught and anchored in the wound against Poupart's ligament. March 10, 1904.	Comfortable; no nervousness, but late suppuration on one side.	Examination, May 17, 1905. Position and condition of uterus and adnexa very good; no pelvic or other symptoms; former marked melancholia, neuralgia and dyspepsia gone; has quite robust health; took tonics about a year.
47. Mrs. T. C., aged 33; multipara; housewife.	Well-built woman; constant left-sided ovarian pain and neuralgias of leg, loin, chest and arm of same side; backache; dyspepsia; constipation and dysmenorrhea.	Large, metritic, retroverted mobile uterus; left tube and cystic ovary prolapsed and adherent; lacerated perineum.	Curettement; perineorrhaphy: liberation of left adnexa: electric cauterization of follicles in left ovary. July 14, 1904.	Smooth, afebrile; primary union.	Examination, May 30, 1905. Normal position and condition of all pelvic organs; several applications tincture iodin required to endometrium; massage and galvanism of uterus to overcome chronic metritis; robust health; former persistent ovarian referred neuralgias gone.
48. Miss M. R., aged 23; virgin; dressmaker.	Poorly nourished, anemic woman; diffuse constant pelvic pains in sides and back, aggravated during menses; no colicky pains; marked dyspepsia; generaly feebleness and nervousness.	Movable retroversion, with apparent retroflexion; catarrhal endometritis; left ovary cystic.	Curettement; electrothermic cauterization of left ovary; special dissection of right ligaments from broad ligaments. July 23, 1904.	Comfortable; primary union.	Examination, June 12, 1905. Position and condition of uterus and adnexa ideal; menses normal and painless; no pelvic or other symptoms; little leucorrhea; good general health.
49. Miss T. D., aged 25; virgin; domestic.	Feeble build; somewhat anemic; constant left-side and backache; dysmenorrhea; dyspepsia; headaches; unable to work.	Small, extremely retroverted, mobile uterus; catarrhal endometritis; cystic left ovary; imperfect development of organs.	Curettement; resection of left ovary; very feeble right ligaments, strengthened by adjacent peritoneum. Oct. 15, 1904.	Afebrile, comfortable; primary union.	Examination, May 16, 1905. Position and condition of uterus and appendages normal, but patient was too feeble to work for about six months, and required one application tincture iodin to endometrium; galvanism to left ovary several times; tonic remedies all the time; she is now in fair health.
50. Mrs. M. I., aged 25; I-para; working housewife.	Fairly nourished, very nervous woman; neurasthenic since railroad injury six months ago; back and side aches constantly; dysmenorrhea; leucorrhea.	Extreme retroversion, movable; adnexa adherent; endometritis; lacerated cervix; cystic left ovary.	Curettement; Emmett cervix operation; resection of left ovary. Oct. 18, 1904.	Normal; primary union.	Examination, April 1905 (Dr. Bernard). Normal position and condition of uterus and adnexa; normal pelvic functions; patient has ophthalmic goiter.

can not ascend with it, as they should, being fixed at a lower plane. The enforced tension on these sensitive structures entails discomfort on the patient; and the direction of this traction is opposed to that of the extraperitoneal (often imperfectly) shortened round ligaments, which endangers their integrity and tends to induce return of displacement of the uterus. Such adhesions of an ovary and tube are severed with the greatest ease by a finger within the internal inguinal rings, because their natural position, fortunately, is just in front of them.

Second: The round ligament does not always slide extensively enough within the broad ligaments without some special intraperitoneal dissection, to impart forward traction to the uterus directly enough; but by the exclusively extraperitoneal technic it is left to pull from the point of its entanglement in the broad ligament, several inches away from the uterus, which manifestly predisposes to a recurrence of retroversion. This condition will be found once in every four or five individual ligaments dealt with, even in simple cases, according to my observations in at least 130 cases, if the effect on the uterus of traction on the shortened ligament be noted each time by a finger introduced alongside of it. This condition is readily corrected by a little dissection around the ligament when this is drawn into the slightly dilated inguinal ring.

Third: In the rather frequent cases of retroversioflexion with a heavy fundus the center of gravity of the body of the uterus is often posterior to a line joining the points of origin of the round ligaments, while the posterior cervical attachments are relaxed and allow it to rise forward. In this condition traction on the round ligament will raise the cervix still more forward quite as often as it will raise the fundus, unless it is quite completely dissected out from the broad ligament on each side and is given a new course almost directly forward. Koenig and Feuchtwanger[14] have also observed this. This dissection and development of the round ligaments in such cases is readily done through the merely dilated rings.

That such intraperitoneal exploration and manipulation needs to be added to the simple Alexander operation, even in the simple cases, is indicated by results of that operation as reported, for instance, by Longyear,[15] who in 58 cases had five recurrences of displacement, even without any test of pregnancy affecting them at all. In consequence of his working outside of the inguinal canals likewise, he did not find either round ligament in one case, and only one in another case. Such inability to find the ligaments is a worse failure of such superficial technic than is a recurrence of displacement after the operation. It is certainly not unfair, therefore, to count such failures with the recurrences of retroversion. These two added to the five recurrences in the Longyear report makes 12.5 per cent. failures in all. This is about equal to the results of the simple Alexander operations as reported by a number of German operators, particularly those who aim not to open the inguinal canals according to Alexander.

Such results are not satisfactory when it is considered that the operation is never a life-saving one, never done for grave indications, and that non-surgical means could largely have been substituted; and, in view of the fact that I have now 155 examined cases, the majority of which were complicated, so much so that pessaries, etc., were out of the question and surgery was positively the only resource. The patients were all carefully examined, on an average nearly two years after operation and only one case of return of displacement was found among them; no hernias, while some fifteen hernias, at least, were incidentally cured; and twenty-one patients who bore one or more children, all passed the double test of pregnancy successfully. Among those gynecologists who, on account of such considerations, have been induced, like myself, to extend the bounds of the Alexander operation, and to give the larger class of complicated cases of this kind the superior benefits of a more thorough bi-inguinal shortening of the round ligaments, are the following: Professor Fritsch of Bonn removed a tubercular tubal tumor through the inguinal ring, and canal incidentally. Barth[16] of Danzig says that an adequate technic for the Alexander operation was only secured when Kocher opened the inguinal canals in doing it. Barth does this and also opens the peritoneum to sever adhesions and to prove the position of the uterus. Rosinski[17] of Koenigsberg opens the peritoneum to get the ligaments dissected out sufficiently. Heinrich[18] of Bremerhafen advocates opening the peritoneum for similar reasons and says that Professor Zweifel of Leipzig does so also. Professor Kossmann[1] of Berlin, last year reported about twenty cases in which he had performed what at that time he baptized as "the Goldspohn operation." Sigmar Stark[19] says that he has been doing this bi-inguinal celiotomy by a little different technic and claims not to have known until two years ago of any of my seven articles on this subject that were out then. McKay[20] of Sydney, Australia, does by this bi-inguinal celiotomy substantially what I do and says, "I found out later that Goldspohn anticipated me; but I can from my experience in the procedure fully endorse his remarks on this innovation, and I have no doubt that it will be only a matter of time when this addition to the Alexander operation will be adopted on all sides . . . Such an easy matter is it to explore the ovaries and tubes through the internal ring, that I am now adopting this method in preference to the median incision when I wish to remove a small ovarian cyst or hydrosalpinx" (in connection with a retroversion, of course).

During the years 1902, 1903 and 1904 I performed this operation on 55 patients. One patient died after 36 hours of very satisfactory condition, from all the signs of cerebral embolism, which suddenly developed, and ended inside of 20 minutes. Of this number five were not accessible for examination, but 49 were examined by me or one of five other physicians after an average interval of twenty-two and one-half months after operation, and are reported in the detailed table. In five of these the uterus was adherent. In nine cases the adnexæ of both sides were adherent and in five of those on one side only. Three hernias were cured incidentally. The tube (five times a hydrosalpinx) and ovary were removed through the dilated rings on the right side four times and on the left side six times. Cystic follicles and corpora lutea or hard cirrhotic portions of ovaries were excised from the right ovary 26 times and from the left ovary 31 times. In a few, this was done by thermocautery. Lateral suspension of tube and ovary was made twice on the right and four times on the left side. Salpingostomy was done twice. Small parovarian cysts were removed twice. Primary union of the inguinal wounds occurred in all but five cases in which a stitch hole abscess or late catgut suppuration ensued on one side. As collateral operations at the same sitting the following were performed: Currettements 49, amputation of cervix 7, Emmett operation 1, my intrapelvic infravaginal perineorrhaphy 15, hemorrhoids by cautery 6, appendectomy by separate small wound made bluntly 1, right nephrorrhaphy 1. Among this group of cases three confessedly induced abortions were reported, and four cases of normal labor at term. In addition to the latter, six cases of normal gestation and labor were also found among the group of cases previously reported—making ten new such "double test" cases to be added to the eleven that I had before, or twenty-one in all; each patient was carefully examined afterward and the uterus found in rather more pronounced anteversion and usually in good involution. The same may be true of two others of whom examinations could not be had as yet. Since my last report I have noted the following similar cases reported by other operators in which the patients were examined after a subsequent labor and found to have no recurrence of displacement, thus having passed what I termed the double test of pregnancy successfully: J. R. King,[21] 3 cases; Professor Fuchs, Werth-Kiel, 6 cases and 1 temporary recurrence; Reiferscheid.[22] Bonn, 9 cases; Steidl,[23] Strassburg. 4 cases: Haid.[24] Buffalo, 12 cases; R. H. Car, Chicago, 5 cases; Heinrich.[25] Bremerhafen, 5 cases; Morlaender.[26] 1 case; John G. Blake.[27] Boston, 3 cases; W. M. Conant,[28] Boston, 6 cases; F. W. Johnson,[29] Boston, 12 cases; L. H. Boldt,[30] New York, 4 cases; P. F. Munde,[31] New York, 4 cases, and W. M. Polk,[32] New York, 4 cases. These, with 10 cases of mine, make 88, of which one only was a temporary recurrence. These are separate from a collection of 80 such cases that I reported three years ago.[33] among which there were two recurrences of displacement (in patients operated on for prolapse). Thus we have 168 cases in all, with only three failures and those for special reasons mostly. Furthermore, Dr. F. W. Johnson says "Dr. Cleveland, New York, with a large experience with the Alexander operation, and Dr. Edward Reynolds, Boston, who has confined many such cases, have never seen a return of displacement in cases after labor following the Alexander operation.

THE CONSERVATION OR RESTORATION OF NORMAL ANATOMY IN GYNECOLOGIC SURGERY.*

DANIEL H. CRAIG, M.D.
Surgeon to Out-Patients, Free Hospital for Women; Instructor in Gynecology, Boston Polyclinic; Fellow of Southern Surgical Gynecological Association, etc., etc.
BOSTON.

During the past few years a great wave of conservatism has agitated the entire gynecologic fraternity, not only throughout this country, but also Europe, although it must be admitted that conservatism has not yet achieved the following it deserves even here. The French and to a less degree the English and German gynecologist still vastly prefers to do a high amputation of the cervix or even a vaginal hysterectomy in cases in which better symptomatic, functional and anatomic cures, together with a more complete conservation of the child-bearing function, may be obtained by a tracheloplasty. In France it is true that ovarian conservation has received great stimulation by the well-known work of Jayle and his confrères in regard to the internal secretion of the ovary. In our own country I feel certain that I am not overstating the fact when I say emphatically that it is now a very rare occurence for a competent gynecologist so far to forget or to neglect the principles designated in the title of this paper as to remove or to sacrifice a healthy, or even a healthy portion of an ovary. This subject, however, has been too frequently and too well exploited by others to demand especial consideration here.

My desire in bringing to your consideration this paper is to extend this tendency to conservatism to include two more large classes of cases which have been often and hotly debated, namely, uterine displacements and plastic gynecologic surgery. If this paper differs from my former papers in showing little, if any, evidence of original research work, its justification must be sought in the extemporaneous remarks of Dr. Seth C. Gordon, of Portland, Me., on the occasion of the complimentary dinner tendered him in honor of his fiftieth year of medical practice on the 6th of June last, in which he said that the highest attainment of any medical man was the ability to think for himself and to form independent, if not original, opinions on each subject, and I ask you to accept what follows as the result of such independent and, perhaps, original thought.

That the paper and its discussion may not be too broad for careful consideration, I have omitted any discussion of the merits of the treatment of uterine displacements by pessary, and shall assume in the following that we are dealing only with cases in which operative treatment has been deemed advisable.

One of the most thoughtless and unscientific assumptions ever made in this connection not only by the medical profession as a whole, but even by many able gynecologists, is that the multiplicity of operative procedures advocated by various operators bears evidence to the fact that no one satisfactory operation has as yet been devised. This, as I shall attempt to prove, is utterly fallacious. It is not only true that one satisfactory operation has been described, but that many such absolutely rational and scientifically, anatomically and symptomatically satisfactory operations have been advocated and are in daily use.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

If any error can be greater than the one just outlined, it is that of assuming that, since some one favorite operation appeals to the appreciation of the rational in gynecology, it is right and wise to adopt that operation and to employ it in the treatment of all cases of the particular form of displacement for which it is considered a remedy. Empiricism is hotly condemned and denied throughout the whole realm of medicine, and yet such an adoption of one operation for all cases of any given uterine displacement constitutes nothing short of extreme empiricism.

To me it seems that the multiplicity, all too limited, testifies to the infinite variety anatomically manifested by such cases and also to the originator's rebellion against the former empirical employment of methods unsatisfactory in certain respects in certain cases. Moreover, being convinced that the originator of each of the better known operations does not in his own practice consider his operation by any means an universal panacea, nor use it exclusively in all his operative cases, I addressed the following letter to each of twelve American originators of such operations:

I am preparing a paper for the coming session of the American Medical Association entitled "The Conservation or Restoration of Normal Anatomy in Gynecologic Surgery." In treating of this subject I wish particularly to commend such operations as restore uterine displacements through the employment of the uterine ligaments, and as you have originated and publicly advocated such an operation, I shall greatly appreciate answers to the following questions:

1. Do you find your operation applicable to all, and do you employ it in all cases of uterine retrodisplacement in which you operate?
2. If not, in what percentage, approximately, do you employ it?
3. Am I at liberty to quote your reply in connection with my paper?

Nine of the twelve gynecologists thus addressed replied at much length, and each and all granted leave to quote their replies, for which I sincerely thank them, and from which I will quote.

Dr. Baldy finds his operation applicable to most cases except those in which, through concomitant or previous operation the round ligament on one or both sides is absent.

Dr. Bovée says: "I do not find my operation applicable to all cases nor do I employ it in all cases of uterine retrodisplacement in which I operate. There are various conditions, such as deep laceration of the cervix, the presence of tumors in the posterior wall of the uterus, habitual constipation with straining at stool, habitual retention of urine, mal-attachment of the uterovesical and uterosacral ligaments to the uterus which may cause retrodisplacements of the uterus, and especially is this so of appendage disease. In such cases, operation on the uterosacral and round ligaments would be manifestly unadvisable."

He uses his method in about one-third of his cases.

Dr. A. Palmer Dudley, New York, finds his operation applicable to about one-fourth of his cases.

Dr. Gilliam says: "I find my operation applicable in all cases, except such as those in which the ligaments are preternaturally short and the uterus is held rigidly in retroposition by conditions that can not be overcome. The percentage is exceedingly small."

Dr. Goffe says: "I wish to say unhesitatingly that I find my operation for the cure of retrodisplacements of the uterus applicable to all cases in which I operate primarily for the displacement.. Sometimes, in cases in which I have submitted a patient to laparotomy, for the relief of conditions other than displacement or complicating it, I shorten the uterosacral ligaments and fortify this procedure by shortening the round ligaments also. In patients at or near the menopause requiring multiple repairs, such as trachelorrhaphy or amputation of the cervix, perineorrhaphy, etc., for brevity I frequently do a vaginal fixation. My operation, however, is the standard procedure."

Dr. Kellogg, finding his original operation inadequate, has devised a second operation, and now rarely needs any other.

Dr. Mann says: "I do not employ it in all cases, but only in those in which for some other purpose I am obliged to open the abdomen, or when the Alexander operation has failed. I do four operations for displacement: the Alexander, my operation for internal shortening, Kellogg's operation and ventral fixation, not suspension.

Dr. Newman says: "In all cases, when it is not necessary to open the abdomen for other work, I employ my 'high or direct' operation for shortening the round ligaments and with uniform good results. When celiotomy is necessary (for intra-abdominal complications) I shorten the ligaments by the intra-abdominal methods."

Dr. Wylie disapproves of ventral suspension and fixation, and reserves his own operation for those cases in which opening the abdomen is necessary for complications, doing the Alexander operation when celiotomy is not necessary.

My reason for making these excerpts at such length is that they seem more potent than any other argument I could offer. When a man has patiently evolved an operation, it becomes to him almost as a part of himself, and any overenthusiasm manifested by him in its behalf is as easily excused as is the more exalted idea of a child excused in its parent. Moreover, we might reasonably expect its originator to be more expert than others in its application and to expect and actually to achieve a greater percentage of successes by its employment than any one else. It seems to me, therefore, that when the foregoing nine gynecologists, each and every one, find from a few to many cases requiring some other operation than their own, it is a strong argument in favor of a great familiarity with the greatest possible number of rational operations for the same condition. In other words, these replies to my letters confirm absolutely my contention, namely, that no one operation will fulfill all indications and that, therefore, a multiplicity of operations is an essential to a broad success. Just here permit me to insist that there is one attainment the possession of which by any operator transcends all other abilities; I allude to mechanical ingenuity.

It is well nigh impossible for the present generation of gynecologists to attain a degree in medicine without a good fundamental education in the anatomy, physiology and pathology of the pelvic organs of women, and we can, therefore, assume that such knowledge is theirs. Assuming that due consideration is given to the functions which the pelvic organs must perform, it is my contention that the operator, having thoroughly familiarized himself with the greatest number of operative procedures for any given condition, and possessed of sufficient mechanical ingenuity to vary any given operation to meet the requirements of his individual cases instead of following absolutely the originator's description, or, if need be, of combining the indicated portions of two or more such operations so as to restore the closest possible approximation of the original normal anatomy, will give the greatest measure of relief to his patients.

No discussion of the merits of any method of operative treatment of retrodeviations of the uterus is complete without comparing the merits of the utilization of the normal anatomic structures with the demerits of the introduction of adventitious, artificial and unnatural uterine supports. In the latter class I, of course, allude to ventral fixation and suspension and vaginal fixation.

I am not prepared to say that ventral fixation or suspension or vaginal fixation are absolutely unjustifiable operations, but I am prepared to say that they are performed far more often than indicated or even justified. This is true for several reasons. The ventral suspension and fixation are by far the easiest operations performed within the abdomen and can be done by any tyro, their safety merely depending on his appreciation and practice of asepsis. No minute knowledge of pelvic anatomy is required, because the operation itself is a violation of every unit of such anatomy.

The only cases in which I have ever considered myself justified in doing a ventral suspension or fixation have been cases in which through concomitant or previous operations, developmental arrest, atrophy due to long persistence of untreated disease, or senile degeneration, the normal supporting structures of the uterus were absolutely unavailable to secure it in its restored normal position. Believe me, if I could only happily convince all physicians that the foregoing constitute the only rational indications for these two operations, and that their performance under any other circumstances constituted an acknowledgement either of inability on the operator's part to do good work with the sufficiently abundant material which Nature has provided and with which the work was originally done, or an inexcusable indifference to the best interests of the patient, these operations would be very rarely performed. Furthermore, should the time ever come, as I hope it will, when these views are widely held, our successors will look back on the era of the undue prevalence of these two operations much as we now look back on venesection.

It is not to the performance of ventral suspension and ventral fixation in properly selected cases by expert operators of wide experience and established ability, possessed of expert selective judgment, that I object. These operations have been advocated and performed by the best gynecologists of the world, and in proper cases—which each year are being more carefully selected, and hence are fewer in proportion to the total number of operations for such conditions—with generally satisfactory results, and this fact alone gives them a valid standing, always, be it understood, in proper cases only.

My objection to the performance of ventral suspension is because of its ease, simplicity and safety by incompetent and inexperienced operators who would not be competent properly to adjust the uterosacral, round and broad ligaments, and who, if ventral suspension had never been devised for them, would still be using the comparatively harmless pessary or referring their patients to competent operators.

It is the too frequent performance of these operations by these occasional or inexperienced operators in cases in which none of the above-named indications for ventral suspension exist, that furnishes the abundant material for dystocias, intestinal obstructions, painful abdominal wounds and other undesirable sequelæ not infrequently observed.

The degree of surgical skill and address necessary for the performance of the operations involving the shortening of the round ligaments, the shortening or transplanting of the uterosacral ligaments and the transplanting of the uterovesical attachment to the cervix with the very vague structures known as the uterovesical ligaments should not be exaggerated. They are all comparatively simple operations, provided only that the operator knows thoroughly his normal anatomy, has the proper instruments and is well based in the technic of the operation which he has elected to form the foundation of the individual operation. For example, so much has been said and written relative to the difficulty of isolating the round ligaments according to the technic of Alexander that in ten consecutive, unselected cases since having this paper in mind I have had my anesthetist accurately note the physical condition of the patient and the time consumed between the making of the initial skin incision to the complete isolation of the round ligament

The findings I have tabulated as follows:

CASE 1.—Patient slight..........	Right ligament	3 min. 10 sec.
	Left ligament	2 min. 35 sec.
CASE 2.—Patient slight..........	Right ligament	2 min. 45 sec.
	Left ligament	3 min. 25 sec.
CASE 3.—Patient moderately stout.	Right ligament	3 min. 20 sec.
	Left ligament	3 min. 15 sec.
CASE 4.—Patient stout..........	Right ligament	11 min. 40 sec.
	Left ligament	3 min. 20 sec.
CASE 5.—Patient slight..........	Right ligament	4 min. 15 sec.
	Left ligament	1 min. 55 sec.
CASE 6.—Patient moderately stout.	Right ligament	8 min. 30 sec.
	Left ligament	3 min. 10 sec.
CASE 7.—Patient slight..........	Right ligament	4 min. 50 sec.
	Left ligament	3 min.
CASE 8.—Patient moderately stout.	Right ligament	7 min. 20 sec.
	Left ligament	4 min. 50 sec.
CASE 9.—Patient stout..........	Right ligament	6 min. 20 sec.
	Left ligament	5 min. 35 sec.
CASE 10.—Patient slight..........	Right ligament	2 min. 40 sec.
	Left ligament	2 min. 15 sec.

This table shows that in these ten cases which were ordinary and unselected, being consecutive, the longest time consumed in isolating the round ligament was in Case 4, in which, through much oozing of blood from a thick, fat layer, the structures becoming obscured by blood staining, 11 minutes and 40 seconds, practically 12 minutes, were consumed in isolating the *first ligament*, only 3 minutes and 20 seconds being required on the left ligament because information acquired in isolating the first ligament always makes the isolation of the second quicker. The average time per ligament was 4 minutes and 27½ seconds, which I feel certain can not be considered excessive, and I feel no hesitation in saying emphatically that any material lengthening of the operation is invariably due to the lack of knowledge of the regional anatomy, a fault easily overcome, or to a careless disregard of proper technic as it was in the isolation of the right ligament of Case 4.

The uterosacral ligaments are not well understood or are misunderstood by many, but when their anatomy is once mastered, which is not in the least difficult, I feel certain that every surgeon who has had experience with them will sustain me in the statement that their isolation and manipulation are relatively easy.

Being, then, possessed of such good means of restoring and conserving normal pelvic anatomy by the employment of only its natural ligaments, except as previously indicated, why should we, through indolence or indifference, fasten the uterus either mediately or immediately to the anterior abdominal wall in a way never accomplished by Nature, in a position as far removed from normal as its retrodeviation for which the operation was undertaken, and with new relations which may interfere to a greater or less extent with the performance of some one or more of its functions unless for very special indications? Last and most important of all, why, when avoidable even at a far greater expenditure of time, energy and skill than is ever demanded by the other operations, put a false band with all its baneful possibilities across from one to several centimeters of the abdominal cavity, when every surgeon in the land would consider himself highly culpable if on accidentally discovering such a band under any other circumstances, he closed the abdomen without first safely removing that band? It is useless to say that such bands do no harm because they may do just as much harm as any other similar false band. It seems little less than a miracle that it has been reported so seldom, but I have personal knowledge of two cases, one terminating fatally, in which subsequent operations were demanded for intestinal obstruction due to such suspensory ligaments, and Dr. J. M. Baldy long ago reported nine such cases. Such risks are, or at least may be, legitimate when urgent symptoms demand relief and no other means offer an equal chance for successful relief, but not otherwise.

All that has been said of the benefits of the multiplicity of methods for the operative treatment of retrodisplacements applies equally well to the plastic operations for the repair of injuries of the birth canal.

How often we read or hear an article warmly advocating some particular method of tracheloplasty or some particular manner of amputating the cervix. This seems to me unwise and unsound if the method is offered as a substitute for others. As a supplement it should be welcomed. Learn thoroughly the basic, fundamental principles of all such operations. Accept what is sound and be prepared to use such principles of any one or several operations as the personal equation of the individual patient may require. It necessitates much work, but the end justifies the means, and those of us who have foresworn all other practices owe it to our patients and to our consultants to know the whole field as thoroughly as work can enable us to learn it. It was to gain time for such work that the other practice was relinquished.

I was greatly pleased at the last session of the American Gynecological Society to hear, as a guest, Dr. E. C. Dudley, in his presidential address, invite the greater attention of the members, and hence, of course, of gynecologists in general, to the performance of plastic, so-called minor, gynecologic operations and to deplore their too frequent relegation to assistants. I consider the restoration to its original normal relations of an old lacerated perineum as the most difficult of gynecologic operations, and I should consider the characterization of a man as a good plastic operator as the highest possible commendation. It is minor gynecology only in the sense of danger to the patient's life. It is probable that no operation is more frequently unsuccessfully performed, especially when the original laceration has led to a complicating cystocele and rectocele.

Here, again, no one operation will mend all cases. It is futile to exploit the advantages of the Hegar, the Tait or the Emmet operation as possessing ability to cure more than a certain percentage of cases. Only two considerations can determine the operation to be performed, namely, the location, extent and direction of the original laceration and the absolute necessity of removing all cicatricial tissue in order that the torn or separated muscles may be so placed as once more to perform their lost functions. Since it is rare to find two tears exactly alike, it is obvious that each of all the operations thus far described have their indications, and it is equally obvious that now and then a laceration will be found which no known operation will exactly repair. Regardless, then, of the size or shape of the adventitious tissue to be removed, the operation must completely remove all tissue abnormally present as the result of the laceration, completely exposing the separated muscles. A mere epithelial denudation is entirely inadequate, as it does not eradicate, but merely lessens the amount of such tissue.

I have no operation to prescribe definitely, but the principles above indicated are applied, with variations to suit each case, as follows: The size and direction of the tear is determined by palpation and inspection of the vaginal mucous membrane, and the outline of all tissue included within the cicatrized area is lightly marked with a sharp scalpel, irrespective of its size or shape. Parenthetically, I may say that an irregular approximation of the denudation suggested by Emmet obtains in about 65 per cent. of the cases. It will be found that this outline invariably terminates at the lowest remnant of the hymen on one or both sides and at some point high or low in the median line.

Having completed this outlining process, which requires but two or three minutes, the entire thickness of the mucous membrane is picked up on a tenaculum or with tooth forceps near and just internally to the lowest point of the hymenial remains and is cut entirely through into the loose areolar tissue. The opening is then carefully enlarged inward until it will admit the tip of the index finger. The entire outlined area is then freed from the underlying muscles and rectum by blunt dissection with the finger only in this loose areolar layer, and as soon as the outline has been slightly passed the entire mass is excised.

The remaining portions are now sutured in whatever way will best serve in the individual case to restore the parts to their original relations. Bleeding is free, but never serious and can always be controlled by the sutures without the necessity of tying any vessels, however the sutures are placed. The only necessity is that care be taken to place them well into the muscles and to avoid either perforating the rectum or allowing dead spaces to remain.

CONCLUSIONS.

The conclusions to be drawn from the work which has inspired this paper are:

1. The greater the number of ways devised for utilizing the normal uterine ligaments for its restoration and retention in its normal position the better, so long as they are rational and safe and considered as supplements to instead of substitutes for each other.
2. Every surgeon, whether specialist or general practitioner, intending to operate in such cases owes it to his profession and to his clientele to familiarize himself with all known methods and to be prepared to use any or all or to modify any or all of them to meet the demands of each individual case.
3. The skill and time required to utilize the natural ligaments are not excessive.
4. The formation and utilization of adventitious ligaments within the abdomen should be reserved for cases manifesting special indications.
5. The operations of ventral suspension and fixation should not be performed because of their ease by pseudo-surgeons who could not competently operate by using the natural ligaments.
6. The individual case should determine the method for each tracheloplasty or cervical amputation for the relief of laceration.
7. Only principles, not details, can be definitely described for the plastic repair of the lacerated perineum.
8. Plastic surgery is minor only in its danger to the patient's life.
9. The conservation or restoration of normal pelvic anatomy is the highest function of the gynecologist.

DISCUSSION

ON PAPERS OF DRS. GOLDSPOHN AND CRAIG.

Dr. C. O. Thienhaus, Milwaukee, agreed with Dr. Craig that for retroflexion of the uterus there are many methods of operation which give satisfactory results, and that the surgeon who has perfected himself in one method and knows not only how to do it, but the indications for it as well, will have excellent results, while others will fail. In the majority of failures it is not the method which is at fault, but the inexperienced operator. Five years ago Dr. Thienhaus advocated the vaginal route and the vaginal fixation either after Mackenrodt's or Dührssen's method for retroflexion of the uterus, and he has had no reason to change his views. Women will consent more readily to operation by the vaginal route, and if this can be performed with the same success and the same immediate and future safety for the patient as by the abdominal route there is no reason why it should not be chosen. By doing a vaginal fixation it is possible to avoid all the objections which are raised to abdominal fixation and suspension, namely, abnormal position of the uterus and the formation of bands, which may cause ileus. Experience, he said, has also shown that when Mackenrodt's or Dührssen's method is used there is absolutely no danger of disturbance during future pregnancies. Dr. Thienhaus has seen eight pregnancies following vaginal fixations which he had performed after Mackenrodt's method (in one case two pregnancies), and in not one of them was there any disturbance attributable to the fixation, during pregnancy or confinement. He does not use the vaginal route for every case of retroflexion. When the retroflexed uterus is imbedded in dense adhesions or when there is sufficient reason to believe that together with a retroflexion of the uterus a disease of the appendix is present he always uses the abdominal route. In 1902 Dr. Goldspohn challenged Dr. Thienhaus to show him literature that would state that Dührssen had so few recurrences. Dr. Thienhaus showed that literature.

Dr. W. O. Henry, Omaha, said that he extends the vesicouterine ligaments upward on the anterior surface of the uterus without dissecting the bladder free from the uterus. The abdomen is opened, all adhesions are broken up, and whatever plastic work is required is done on the appendages, then the peritoneum is carefully scarified in the cul-de-sac between the uterus and the bladder, and the scarification is extended up on the uterine wall in line with the vesicouterine ligaments as far as may be necessary, depending on the size of the body of the uterus, then the bladder is sewed to the uterus for the distance of about one-quarter of an inch with a simple catgut ligature, the vesicouterine ligaments are picked up and sewed to the scarified surface with a like catgut ligature. This simply makes use of Nature's method to hold the uterus forward. Dr. Henry related the case of a young woman who, from pelvic inflammation, had a retroflexed uterus with adhesions. He advised an operation, but it was refused, until five years afterward the patient returned for operation. The abdomen was opened, the adhesions broken up, tubes and ovaries released, and the cysts in the ovaries punctured; the uterus was then brought forward according to the above plan. The woman made a good recovery. Five weeks later a careful examination showed the uterus to be in excellent position and freely movable. Dr. Henry believes that the Alexander and Goldspohn operations are all right in certain cases, but that his method of operation is rational, practicable and applicable in a large majority of cases. He thinks it well after this operation to have the patient lie on the side and face as much as possible until the parts gain their normal tone.

Dr. A. Ernest Gallant, New York, agreed with Dr. Craig that one operation will not suit every case. Experience teaches that any disease or operation which induces adhesions of pelvic organs produces a painful point. Normally the uterus should be capable of elevation of from four to five inches, and the lateral mobility is from two to three inches. The moment adhesions form, either from inflammation or other cause, the least dragging on that point will cause pain; hence Dr. Gallant avoids any operation which will cause restrictive artificial adhesions. For this reason he has avoided shortening the uterosacral ligaments. In his experience as high as 50 per cent. of patients suffer from this cause. In a study of 2,000 gynecologic cases trying to lift the uterus caused pain in 50 per cent. In some cases, of course, this was associated with pus tubes and other inflammations. If the uterus is placed in such a position that it can freely move up and down with every breath, then pain is avoided. In the Alexander operation the uterus is thrown forward and the ligaments shortened to such a point that the uterus by dragging thereon will produce pain. Dr. Gallant has made use of the Alexander operation but once. The number of patients he has seen with inguinal pain after that operation has led him to avoid it. The suspension operations of Ferguson and others are more favorable because while they fix the round ligaments at their middle the elasticity of those overstretched ligaments is such that it will not interfere with the rise and fall of the uterus. Dr. Gallant has seen several cases associated with the Alexander or with a ventral suspension in which there has been painful dragging on the scars. The operation he has used for the past five years is one which he first saw performed by Dr. Jarman. It consists of putting a needle threaded with catgut through the broad ligament, around the middle of the round ligament and stitching it to the peritoneal surface on either side of the median incision. There is no scarification, simply the sutures, two on each side, about half an inch apart. It is a very simple operation and it has been a successful one. In Dr. Gallant's cases the trouble has not recurred so far; one woman has been pregnant twice, and the uterus is still in good position. In thus suturing all that is done is to tip the uterus forward just far enough that intra-abdominal pressure will be exerted on the upper posterior portion of the fundus; and the force will be maintained in the right direction, driving the fundus toward the symphysis.

Dr. E. G. Frisbee, San Francisco, performs an operation which consists of detaching the round ligament at its junction with the uterus. He passes a pair of forceps through the broad ligament beneath the ovarian ligament and tube, seizes the detached round ligament, brings it around back of the uterus, and stitches the end of the one round ligament to the other, first making a slight furrow in the posterior wall of the uterus. He covers all the raw surfaces with peritoneum so that adhesions can not form. This tilts the uterus forward. He has used this method with success for four or five years. Only one patient has been pregnant so far as he knows. The operation can be performed eaily.

Dr. E. F. Tucker, Portland, said that many drugs are recommended in vomiting of pregnancy because many of them are useless, and that in retroversion of the uterus many operations are recommended by different operators, but none of them is perfect. If physicians could make use of Nature's own method to restore the uterus to its position it would be a good thing. There are no ligaments to pull the uterus forward; the forward position of the uterus depends on the erect position of the woman. Animals walking on all fours do not have retroverted uteri. In the child the uterus normally is much higher in the pelvis and has a backward position, which remains, to a large extent, throughout infancy. It does not begin to antevert until the infant begins to walk. The backs of infants are flat, but when they begin to walk the pelvis is tilted forward, the lumbar curve is produced, and the intra-abdominal pressure tilts the uterus forward. Dr. Emmett used to say that the uterus was swung from above, and so it is. There may be a shortening of the broad ligaments so that the uterus will not come down completely. There are congenital cases of retroversion of the uterus. There are hundreds of women with retroverted uteri who do not suffer from this condition. It is not really a disease in itself, but it is the result often of widely divergent causes, and the condition can not be cured unless the cause is removed. By looking into the pelvis when the uterus lies forward it will be seen that the round ligaments run backward, outward and then forward through the inguinal canal. If the round ligaments of a normally located uterus are pulled on the organ will be drawn backward and upward. Dr. Tucker does not think that any of these operations are very good. He does the suspension operation, although it is only substituting one pathologic condition for another.

safely removing that band? It is useless to say that such bands do no harm because they may do just as much harm as any other similar false band. It seems little less than a miracle that it has been reported so seldom, but I have personal knowledge of two cases, one terminating fatally, in which subsequent operations were demanded for intestinal obstruction due to such suspensory ligaments, and Dr. J. M. Baldy long ago reported nine such cases. Such risks are, or at least may be, legitimate when urgent symptoms demand relief and no other means offer an equal chance for successful relief, but not otherwise.

All that has been said of the benefits of the multiplicity of methods for the operative treatment of retrodisplacements applies equally well to the plastic operations for the repair of injuries of the birth canal.

How often we read or hear an article warmly advocating some particular method of tracheloplasty or some particular manner of amputating the cervix. This seems to me unwise and unsound if the method is offered as a substitute for others. As a supplement it should be welcomed. Learn thoroughly the basic, fundamental principles of all such operations. Accept what is sound and be prepared to use such principles of any one or several operations as the personal equation of the individual patient may require. It necessitates much work, but the end justifies the means, and those of us who have foresworn all other practices owe it to our patients and to our consultants to know the whole field as thoroughly as work can enable us to learn it. It was to gain time for such work that the other practice was relinquished.

I was greatly pleased at the last session of the American Gynecological Society to hear, as a guest, Dr. E. C. Dudley, in his presidential address, invite the greater attention of the members, and hence, of course, of gynecologists in general, to the performance of plastic, so-called minor, gynecologic operations and to deplore their too frequent relegation to assistants. I consider the restoration to its original normal relations of an old lacerated perineum as the most difficult of gynecologic operations, and I should consider the characterization of a man as a good plastic operator as the highest possible commendation. It is minor gynecology only in the sense of danger to the patient's life. It is probable that no operation is more frequently unsuccessfully performed, especially when the original laceration has led to a complicating cystocele and rectocele.

Here, again, no one operation will mend all cases. It is futile to exploit the advantages of the Hegar, the Tait or the Emmet operation as possessing ability to cure more than a certain percentage of cases. Only two considerations can determine the operation to be performed, namely, the location, extent and direction of the original laceration and the absolute necessity of removing all cicatricial tissue in order that the torn or separated muscles may be so placed as once more to perform their lost functions. Since it is rare to find two tears exactly alike, it is obvious that each of all the operations thus far described have their indications, and it is equally obvious that now and then a laceration will be found which no known operation will exactly repair. Regardless, then, of the size or shape of the adventitious tissue to be removed, the operation must completely remove all tissue abnormally present as the result of the laceration, completely exposing the separated muscles. A mere epithelial denudation is entirely inadequate, as it does not eradicate, but merely lessens the amount of such tissue.

I have no operation to prescribe definitely, but the principles above indicated are applied, with variations to suit each case, as follows: The size and direction of the tear is determined by palpation and inspection of the vaginal mucous membrane, and the outline of all tissue included within the cicatrized area is lightly marked with a sharp scalpel, irrespective of its size or shape. Parenthetically, I may say that an irregular approximation of the denudation suggested by Emmet obtains in about 65 per cent. of the cases. It will be found that this outline invariably terminates at the lowest remnant of the hymen on one or both sides and at some point high or low in the median line.

Having completed this outlining process, which requires but two or three minutes, the entire thickness of the mucous membrane is picked up on a tenaculum or with tooth forceps near and just internally to the lowest point of the hymenial remains and is cut entirely through into the loose areolar tissue. The opening is then carefully enlarged inward until it will admit the tip of the index finger. The entire outlined area is then freed from the underlying muscles and rectum by blunt dissection with the finger only in this loose areolar layer, and as soon as the outline has been slightly passed the entire mass is excised.

The remaining portions are now sutured in whatever way will best serve in the individual case to restore the parts to their original relations. Bleeding is free, but never serious and can always be controlled by the sutures without the necessity of tying any vessels, however the sutures are placed. The only necessity is that care be taken to place them well into the muscles and to avoid either perforating the rectum or allowing dead spaces to remain.

CONCLUSIONS.

The conclusions to be drawn from the work which has inspired this paper are:

1. The greater the number of ways devised for utilizing the normal uterine ligaments for its restoration and retention in its normal position the better, so long as they are rational and safe and considered as supplements to instead of substitutes for each other.
2. Every surgeon, whether specialist or general practitioner, intending to operate in such cases owes it to his profession and to his clientele to familiarize himself with all known methods and to be prepared to use any or all or to modify any or all of them to meet the demands of each individual case.
3. The skill and time required to utilize the natural ligaments are not excessive.
4. The formation and utilization of adventitious ligaments within the abdomen should be reserved for cases manifesting special indications.
5. The operations of ventral suspension and fixation should not be performed because of their ease by pseudo-surgeons who could not competently operate by using the natural ligaments.
6. The individual case should determine the method for each tracheloplasty or cervical amputation for the relief of laceration.
7. Only principles, not details, can be definitely described for the plastic repair of the lacerated perineum.
8. Plastic surgery is minor only in its danger to the patient's life.
9. The conservation or restoration of normal pelvic anatomy is the highest function of the gynecologist.

DISCUSSION

ON PAPERS OF DRS. GOLDSPOHN AND CRAIG.

Dr. C. O. Thienhaus, Milwaukee, agreed with Dr. Craig that for retroflexion of the uterus there are many methods of operation which give satisfactory results, and that the surgeon who has perfected himself in one method and knows not only how to do it, but the indications for it as well, will have excellent results, while others will fail. In the majority of failures it is not the method which is at fault, but the inexperienced operator. Five years ago Dr. Thienhaus advocated the vaginal route and the vaginal fixation either after Mackenrodt's or Dührssen's method for retroflexion of the uterus, and he has had no reason to change his views. Women will consent more readily to operation by the vaginal route, and if this can be performed with the same success and the same immediate and future safety for the patient as by the abdominal route there is no reason why it should not be chosen. By doing a vaginal fixation it is possible to avoid all the objections which are raised to abdominal fixation and suspension, namely, abnormal position of the uterus and the formation of bands, which may cause ileus. Experience, he said, has also shown that when Mackenrodt's or Dührssen's method is used there is absolutely no danger of disturbance during future pregnancies. Dr. Thienhaus has seen eight pregnancies following vaginal fixations which he had performed after Mackenrodt's method (in one case two pregnancies), and in not one of them was there any disturbance attributable to the fixation, during pregnancy or confinement. He does not use the vaginal route for every case of retroflexion. When the retroflexed uterus is imbedded in dense adhesions or when there is sufficient reason to believe that together with a retroflexion of the uterus a disease of the appendix is present he always uses the abdominal route. In 1902 Dr. Goldspohn challenged Dr. Thienhaus to show him literature that would state that Dührssen had so few recurrences. Dr. Thienhaus showed that literature.

Dr. W. O. Henry, Omaha, said that he extends the vesicouterine ligaments upward on the anterior surface of the uterus without dissecting the bladder free from the uterus. The abdomen is opened, all adhesions are broken up, and whatever plastic work is required is done on the appendages, then the peritoneum is carefully scarified in the cul-de-sac between the uterus and the bladder, and the scarification is extended up on the uterine wall in line with the vesicouterine ligaments as far as may be necessary, depending on the size of the body of the uterus, then the bladder is sewed to the uterus for the distance of about one-quarter of an inch with a simple catgut ligature, the vesicouterine ligaments are picked up and sewed to the scarified surface with a like catgut ligature. This simply makes use of Nature's method to hold the uterus forward. Dr. Henry related the case of a young woman who, from pelvic inflammation, had a retroflexed uterus with adhesions. He advised an operation, but it was refused, until five years afterward the patient returned for operation. The abdomen was opened, the adhesions broken up, tubes and ovaries released, and the cysts in the ovaries punctured; the uterus was then brought forward according to the above plan. The woman made a good recovery. Five weeks later a careful examination showed the uterus to be in excellent position and freely movable. Dr. Henry believes that the Alexander and Goldspohn operations are all right in certain cases, but that his method of operation is rational, practicable and applicable in a large majority of cases. He thinks it well after this operation to have the patient lie on the side and face as much as possible until the parts gain their normal tone.

Dr. A. Ernest Gallant, New York, agreed with Dr. Craig that one operation will not suit every case. Experience teaches that any disease or operation which induces adhesions of pelvic organs produces a painful point. Normally the uterus should be capable of elevation of from four to five inches, and the lateral mobility is from two to three inches. The moment adhesions form, either from inflammation or other cause, the least dragging on that point will cause pain; hence Dr. Gallant avoids any operation which will cause restrictive artificial adhesions. For this reason he has avoided shortening the uterosacral ligaments. In his experience as high as 50 per cent. of patients suffer from this cause. In a study of 2,000 gynecologic cases trying to lift the uterus caused pain in 50 per cent. In some cases, of course, this was associated with pus tubes and other inflammations. If the uterus is placed in such a position that it can freely move up and down with every breath, then pain is avoided. In the Alexander operation the uterus is thrown forward and the ligaments shortened to such a point that the uterus by dragging thereon will produce pain. Dr. Gallant has made use of the Alexander operation but once. The number of patients he has seen with inguinal pain after that operation has led him to avoid it. The suspension operations of Ferguson and others are more favorable because while they fix the round ligaments at their middle the elasticity of those overstretched ligaments is such that it will not interfere with the rise and fall of the uterus. Dr. Gallant has seen several cases associated with the Alexander or with a ventral suspension in which there has been painful dragging on the scars. The operation he has used for the past five years is one which he first saw performed by Dr. Jarman. It consists of putting a needle threaded with catgut through the broad ligament, around the middle of the round ligament and stitching it to the peritoneal surface on either side of the median incision. There is no scarification, simply the sutures, two on each side, about half an inch apart. It is a very simple operation and it has been a successful one. In Dr. Gallant's cases the trouble has not recurred so far; one woman has been pregnant twice, and the uterus is still in good position. In thus suturing all that is done is to tip the uterus forward just far enough that intra-abdominal pressure will be exerted on the upper posterior portion of the fundus; and the force will be maintained in the right direction, driving the fundus toward the symphysis.

Dr. E. G. Frisbee, San Francisco, performs an operation which consists of detaching the round ligament at its junction with the uterus. He passes a pair of forceps through the broad ligament beneath the ovarian ligament and tube, seizes the detached round ligament, brings it around back of the uterus, and stitches the end of the one round ligament to the other, first making a slight furrow in the posterior wall of the uterus. He covers all the raw surfaces with peritoneum so that adhesions can not form. This tilts the uterus forward. He has used this method with success for four or five years. Only one patient has been pregnant so far as he knows. The operation can be performed eaily.

Dr. E. F. Tucker, Portland, said that many drugs are recommended in vomiting of pregnancy because many of them are useless, and that in retroversion of the uterus many operations are recommended by different operators, but none of them is perfect. If physicians could make use of Nature's own method to restore the uterus to its position it would be a good thing. There are no ligaments to pull the uterus forward; the forward position of the uterus depends on the erect position of the woman. Animals walking on all fours do not have retroverted uteri. In the child the uterus normally is much higher in the pelvis and has a backward position, which remains, to a large extent, throughout infancy. It does not begin to antevert until the infant begins to walk. The backs of infants are flat, but when they begin to walk the pelvis is tilted forward, the lumbar curve is produced, and the intra-abdominal pressure tilts the uterus forward. Dr. Emmett used to say that the uterus was swung from above, and so it is. There may be a shortening of the broad ligaments so that the uterus will not come down completely. There are congenital cases of retroversion of the uterus. There are hundreds of women with retroverted uteri who do not suffer from this condition. It is not really a disease in itself, but it is the result often of widely divergent causes, and the condition can not be cured unless the cause is removed. By looking into the pelvis when the uterus lies forward it will be seen that the round ligaments run backward, outward and then forward through the inguinal canal. If the round ligaments of a normally located uterus are pulled on the organ will be drawn backward and upward. Dr. Tucker does not think that any of these operations are very good. He does the suspension operation, although it is only substituting one pathologic condition for another.

Dr. H. O. Marcy, Boston, agreed with Dr. Tucker that physicians should study pelvic conditions more carefully. Dr. Marcy gave up the Alexander operation long ago, because he was having failures and not successes. He never operates for the replacing of a retroverted uterus without opening the abdomen. The intrafolding of the round ligament may be all one requires, and if they are folded forward the broad ligaments are shortened, thus aiding materially in holding the uterus forward. In quite a number of cases Dr. Marcy has done anterior ventrosuspension, but there is no one method that accomplishes all that is desired.

Dr. A. Goldspohn said that it is self-evident that any one of these operations can not suit all cases. He agreed with Dr. Craig that the procedures which he and some of the other speakers have mentioned are supplemental to each other. Vaginal fixation and ventral suspension are so far removed from normal anatomy and physiology, and so far behind other operations in their clinical results, that they stand no comparison at all. The men who have done ventral suspension have been challenged to go honestly after their patients who have borne children, to examine them and to see whether or not the majority of them have not a return of the retroversion. Recently one man did attempt to do this and reported on 445 cases out of about 900 in the Johns Hopkins Hospital, and the results are exceedingly poor. In women who can conceive, not those who can not, the bulk of operators in this country and abroad have practically discarded vaginal fixation and ventrofixation. Dührssen, Mackenrodt and their students, however, still plead desperately for these operations, but that their clinical results are not satisfactory to themselves is evident from their frequent changes in technic. That any man can show ten consecutive cases of vaginal fixation without trouble in confinement and without a recurrence of a retroversion afterward Dr. Goldspohn doubts very much. In a court of law it would not do to say that the uterus in any given case remains in good position, because the patient says that she feels well, and that, therefore, it is not necessary to examine her. Such evidence without an examination is equally inadmissible before the tribunal of science. Dr. Goldspohn said that out of 200 cases, most of them complicated, in which his bi-inguinal operation had been performed, he has now a collection of 155 patients who have been carefully examined after an average interval of twenty months after operation. In all this number there is a return of retroversion in only one case. There is not one hernia, while at least fifteen concomitant herniæ were incidentally cured. Twenty-one patients had given birth to one or more children each, and the only abnormal labor reported was a breech presentation in one case. In none of them was there a return of displacement. On the contrary, the anteversion in these cases after childbirth was generally more pronounced than in the others. This feature has been mentioned by several German operators. In the total of over 288 patients, no case of marked peritonitis, etc., occurred to impeach the intraperitoneal manipulations without sight and without drainage. One death occurred from cerebral embolism. This rare occurrence could take place after the same intrapelvic work performed by any other form of ventral section. One other death occurred from hemorrhage due to slipping of a ligature from the stump of a tube and ovary that were removed on one side. In this case the smallness of the wound may have had something to do with the accident. The resulting mortality of a little less than 1 per cent. is less than would probably have been the case if a regular median section with its consequent greater exposure of viscera had been made. Dr. Goldspohn thinks that the fact that he has only one case of recurrence of displacement in 155 cases, and results otherwise also never before equaled by any one in a similar grade of cases is because he has carefully discriminated and selected the cases suitable for bi-inguinal shortening of the round ligaments, and has performed other operations as well. He always excluded the cases of prolapsed uterus from the bi-inguinal domain, which can not cope with the excessive elongation of the sacrouterine ligaments in those cases. In women who can no longer conceive, the retroversion, if present, should also be corrected, but it is usually more of an auxiliary surgical act, associated with some other more pronounced indication, and for this purpose any one of the otherwise rational and effective fixation operations may be eligible.

Dr. D. H. Craig said that the silence of the ardent advocates of ventral suspension and fixation gratified him, while at the same time mortifying him, because either his exposition of their side of the question is not worthy of consideration, or his opinion has been held universally, and shows that his paper was superfluous. He believes that in a few decades ventral suspension and fixation will be considered, except in such cases as he outlined in which they are specially indicated, as we now look on venesection, except in specially indicated cases. The question of the consent of the patient ought not to enter into any consideration of the choice of operation. Getting the consent of the patient depends more on the man trying to get it than on the merits of the operation proposed, and gynecologists ought not to allow themselves to be induced to select a secondary operation unless it is indicated. The question as to the rationality of an operation is not an entity. There are good and bad operations. A bad operation can be so well used as to make it a good operation, and a good operation can be performed so badly as to make it absolutely useless. The personal equation of the operator and selection of cases comes in everywhere. If the operation is not a good one, the gynecologist should study the anatomy and mechanics of the pelvis until he can make a good one. In regard to the question of the holding up of the uterus by a ligament from above, Dr. Craig said that he does not remember when camping out of ever having seen any ropes that held his tent in the air, and the ligaments of the uterus perform the same functions as do the guy ropes for a tent. When normal ligaments can be used to restore a normal condition, the surgeon should not try to improve on Nature, but should follow her as closely as he can. One can improve on perverted Nature, but not on a normal condition. Any operation for retroversion does not produce an immunity in that woman to a recurrence of the retroversion, even if the proper operation has been done. There is as much to be done in teaching the woman how to avoid subsequent retroversion as in correcting it operatively. Dr. Craig does not want to go on record as having the opinion that anything will do for a woman who can not have children. That woman is entitled to as much consideration as the woman who can bear children, and she must be relieved of her pain and discomfort and made as happy and comfortable as any other woman.

CULTURES FROM THE BLOOD IN TYPHOID.

REPORT ON EXAMINATION OF EIGHTY-EIGHT CASES.*

RALPH DUFFY, M.D.
PITTSBURG.

While scattered reports of the occurrence of typhoid bacilli in the blood of typhoid patients extend over a period of twenty years, it is only within the last five or six years that published accounts of larger series of cases occur, and it remains for the present workers to demonstrate to the practitioner what I believe to be the case, that blood cultures in typhoid fever afford a surer and earlier means of diagnosis than the Widal reaction and are perfectly feasible in family practice.

The earliest publication on blood cultures in typhoid I have been able to find is that of Fraenkel[1] in 1885. This observer in seven cases demonstrated the bacilli in the blood in one case. Twelve years later Künau[2] reported that he had demonstrated the bacilli in eleven out of forty-one cases. In this country Cole,[3] of Johns Hopkins, in 1901, in fifteen cases isolated the bacilli in eleven cases. His earliest case was on the sixth day.

[2] Kuenau: Zeits. f. Hygiene, 1897.

[3] Cole: Johns Hopkins Hosp. Bull., July, 1901.

In the same year Auerbach,[4] in Germany, in ten cases, reported positive results in seven cases. His results are remarkable in that he withdrew only from ten to thirty drops of blood for the test, whereas most observers withdraw at least 5 c.c. Hewlett,[5] also writing in 1901, examined twenty-four cases. He does not give the proportions, but thinks that the bacilli are present in the blood in the majority of cases.

Kerr and Harris,[6] in 1902, reported fifty-six cases in which cultures were made. Thirty-one cases were positive and twenty-five negative. They found that in the first week of the disease 87.5 per cent. of the cases were positive; in the second, 70 per cent.; in the third, 50 per cent. They give the general average as 70 per cent.

Courmont,[7] of Lyons, in 1903, in thirty-seven cases, found the bacilli constantly from the first day to the third week. He used fluid cultures and from 2 to 4 c.c. of blood. He found staphylococci in five cases and the colon bacillus in one case. Courmont's belief is that the bacilli are constantly in the blood from the fifth to the twenty-seventh day, but not after the fourth week. Rosenberger,[8] in 1903, in his excellent article on blood cultures, states that in 535 cases collected by him from the literature results were positive in 80 per cent.

The earliest observers used solid media for their cultures. They soon found, however, that it was much better to use fluid media and in such quantity (from ten to fifty times the amount of the blood withdrawn) as to counteract the antitoxic powers of the blood serum.

My own cases in which the blood cultures were taken number eighty-eight. The material was obtained from the medical wards of the Western Pennsylvania Hospital. The patients in these wards are, in the great majority of cases, Italian and Slavish laborers, not speaking English. The fact, together with the ignorance of this class of patients as a whole, makes history-taking extremely unreliable. For this reason I have divided the cases according to temperature at time of test. The rule is for patients to be brought in with a temperature of 103 F. or over and a history of about a week's sickness. My Class A, at 103 F., represents approximately the second week of the disease. I think in no case was a culture made while the temperature was rising before the end of the first week.

The Classes B and C, at 102 and 101 F., correspond to the third week, Class D, 100 F., being somewhere in the fourth week.

The Widal test was positive in all cases but two. In eighteen cases of the series the blood cultures showed bacilli in the blood before the Widal test was positive. In the cases in which the typhoid bacillus was isolated no control cultures were made to exclude the possibility of air contamination.

The eighty-eight cases in which observations were made were routine cases and were not especially typical or severe cases selected for experiment. The mortality was not especially high. Eleven cases were fatal.

The technic I have adopted is to obtain blood from the arm veins in a sterile glass pipette of 10 c.c. capacity by suction with a rubber bulb. A tourniquet is used and the spot to be punctured is touched with pure carbolic acid for a few seconds and then rubbed off with alcohol. The needle I use is a large-sized hypodermic needle, which is thrust through the carbolized area of the skin into the vein; 10 c.c. were withdrawn in almost all cases. In one or two cases lesser amounts were withdrawn; 4 c.c. is the smallest amount in the series. The slight operation takes only about three or four minutes, and the pain experienced is not greater than in the use of the hypodermic needle.

The blood is put into bouillon flasks of 500 c.c. capacity which are kept in the incubator for forty-eight hours before being opened. The bacillus at this dilution (1:50) generally grows in thirty-six hours. In a few cases, however, positive results were obtained only at the end of four days. Growth and agglutination went hand in hand in a number of cultures.

In four cases of the series the typhoid bacilli were non-motile on all cultures. In about one-third of the cases the growth on potato was vigorous and visible.

Class A.—Twenty-one cases; temperature 103 or over; second week of disease.

Sterile	0
Typhoid bacillus present alone	21
Typhoid bacillus present with other organisms	0
Other organisms alone present	0

Class B.—Thirty cases; temperature 102, third week of disease.

Sterile	0
Typhoid bacillus, present alone	25
Typhoid bacillus present with other organisms	5
Other organisms alone present	0

Class C.—Thirteen cases, temperature 101, third week of disease.

Sterile	3
Typhoid bacillus present alone	9
Typhoid bacillus present with other organisms	0
Other organisms alone present	1

Class D.—Ten cases; temperature 100, fourth week of disease.

Sterile	3
Typhoid bacillus present alone	1
Typhoid bacillus present with other organisms	0
Other organisms alone present	6

Class E.—Seven cases; temperature 99, fourth week and after.

Sterile	4
Typhoid bacillus present alone	1
Typhoid bacillus present with other organisms	0
Other organisms alone present	2

Class F.—Seven cases; temperature 98.4 fourth week and after.

Sterile	6
Typhoid bacillus present alone	0
Typhoid bacillus present with other organisms	0
Other organisms alone present	1

From the above table it will be seen that in fifty-six cases in which the temperature was above 102 the bacilli were present in the blood in every case, and that in twenty-three cases in which the temperature was 100 or 101 F. the bacilli were cultivated from the blood in ten cases, or 43 per cent.

AUXILIARY ORGANISMS.

The most interesting result of the examination was the demonstration of auxiliary organisms in the blood stream.

In Class A, in twenty cases, no other organisms than the typhoid bacillus was found.

In Class B, in thirty cases, other organisms were found accompanying the typhoid bacillus in five cases. These organisms were all motile bacilli, decolorizing by Gram's method of staining, and identical in their growth in milk, where strong alkalinity was produced, and in their vigorous, yellow, moist growth on potato. They differed somewhat in growth on agar. None could be agglutinated with serum, 1/20. None produced glass in glucose media. In general they resembled *Bacillus alcaligenes* closely.

In Class C, in thirteen cases, but one organism (*Streptococcus pyogenes*) other than typhoid was encountered.

In Class D, in ten cases, other organisms were present in six cases. Five of these were bacilli corresponding closely to *Bacillus alcaligenes*, though two were non-motile. Cocci (non-pyogenic) were found in one case; *Staphylococcus albus* in one case.

In Class E, in seven cases, two showed other organisms, in one case a motile bacilli and in the other *Staphylococcus albus*.

In Class F, with normal temperature, in seven cases, a white coccus was found in one case.

SUMMARY.

1. *Bacillus typhosus* is present in the blood in all cases of typhoid fever in the second and third weeks, when the temperature is 102 or over.
2. Bacilli of the "enteric group" of bacteria (*Bacillus alcaligenes*) are present in a considerable percentage of the cases after the second week, at first accompanying *Bacillus typhosus,* then supplanting it.
3. Later in the disease cocci may be in the blood.
4. *Bacillus coli communis* is never present in the blood of typhoid patients.

METHYL ALCOHOL AMBLYOPIA, WITH SPECIAL REFERENCE TO OPTIC NERVE.

REPORT OF CASE.*

C. S. G. NAGEL, M.D.
SAN FRANCISCO.

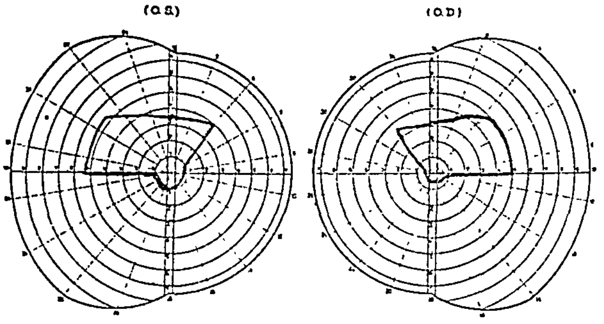
The very meritorious report of Drs. Buller and Wood[1] has absolutely established the specifically deleterious effect of wood alcohol on the optic nerve. Until anatomic findings may give us a better insight into the pathology, cases offering special clinical features seem to me to be worth recording.

Previous History.—It has been my good fortune to come across the patient in Case 80 of the report referred to and to have had this individual under observation for about a year. It is only necessary to recall here that early in October, 1901, this patient became absolutely blind for a number of hours through acute wood alcohol intoxication from imbibing; then a very considerable improvement had been present for some hours, after which blindness had set in again lasting for several days. After improving for a few months, vision had been, on a whole, getting worse ever since. It is noteworthy to quote from Dr. J .F. Van Kirk's report as follows: "This case was characterized by frequent transient changes. The vision would be markedly improved for a few hours and then it would suddenly fail. Often the morning vision would be good, while exercise seemed to increase the amblyopia." The patient further stated to me that he always used to see much worse temporarily whenever discouraged about failure o secure food. He had also had occasionally "fullness of ead" and attacks of pain over the head, which felt "tight" rom forehead to top, but not farther back.

Examination.—When I first had occasion to examine him (March, 1904) vision was R. 5/15; L. fingers in 0.65 m. Anterior chambers were normal o. u. Left pupil was dilated. T. normal o. u. In each pupil there was slow minimum reaction to light. R. F. V. extremely contracted, from 50 degrees outward over ca. 50 degrees outward and upward, 30 degrees upward and 35 degrees inward—up to 5 degrees for the remaining 5/8 of the field. In other words, over ½ of total F. V. is missing, below and inward, and upward and outward F. V. is contracted. There are small fields for blue, red and green and no central scotoma. L. F. V. is analogous, though uniformly a very little wider, but color perception for blue only. The striking point regarding the fields is the similarity as to the position in each of the parts intact and missing.

Corpus vitreum normal o. u. Ophthalmoscopically, the disc in both eyes is white (atrophic), with well-marked lamina cribrosa, outlines sharp, arteries a very little contracted. There is a halo around each papilla. Each disc shows glaucomatous cupping upward. To do away with one other point, I will say that for some time, during the beginning of my observation, there were apparent, at times, two or three discolored small roundish spots in the macular region of right eye which had created in the mind of another casual observer the impression of impending anatomic changes. During my long observation I have become convinced that such is not the case, and that the changes are confined in each eye to the disc, to its immediate neighborhood and to the vessels.[2]

Treatment and Result.—For reasons which will become clear from the epicrisis, I promptly performed a broad peripheral iridectomy in both eyes. For a short time only (ca. 2 weeks) after operation both pupils became a little smaller. The ophthalmometer showed R. + 1.0 axis 60 temp., L. + 3.0 ax. 75 nas. In the right eye vision remained about the same, in the left eye there was a decided improvement. Fingers were now counted (one week after operation) in 1.0 m., and 3 weeks p. o. in 1.25 m. These results of repeated examinations became the more convincing (as generally in cases of extreme amblyopia) because the patient, in trustworthy statements, had repeatedly spontaneously maintained improvement of vision from his observations in general. As a result of repeated perimetric examinations there also seemed to be a slight improvement in both F. F. V. peripherally. Such was the status to about the middle of April, 1904. Soon afterward, however, and gradually more and more pronouncedly, a decided deterioration set in again. In R. F. V. there soon remained but a small field for blue (only), and besides a perception of green could be found occasionally paracentrally. The left eye has kept a still smaller field for blue up to the end of my observation. F. F. V. could only be taken with finger fixation from about August, 1904. In the beginning of November, 1904, the patient was taken to the City and County Hospital, where a careful general examination by Dr. Schmoll revealed nothing abnormal except induration on one pulmonary apex. The patellary reflexes were rather exaggerated, no Romberg. Urine was normal. While, unfortunately, I find nothing before in my notebook regarding the point, the corneæ are now of subnormal sensibility to touch. Only fingers are counted in each eye in about 1.0 m. Left pupil was dilated. T. normal o. u.



On November 16, sympathectomy of the left superior ganglion was performed by Dr. Stillman, under chloroform-anesthesia. In taking up the ganglion and at the moment of cutting, a slight pupillary play was noted, there was no marked dilatation. Both pupils were somewhat contracted while the patient was fully under the influence of the anesthetic. Postoperative tension was a little subnormal. Ten hours after operation both conjunctivæ bulbi were congested. L. T. is still subnormal (decidedly less than R. T.). Patient complained of some trouble in swallowing.

L. Pu. < R. Pu. (before operation opposite!).

Nov. 17, 1904; L. conjunctiva bulbi injected (not R.). L. Pu. < R. Pu. L. T. < R. T.

Nov. 19, 1904: L. T. < R. T. though a little higher than so far since operation. L. Pu. < R. Pu.

Nov. 24, 1904: L. T. < R. T. L. Pu. < R. Pu.

Nov. 28, 1904: Stat. id. left eye better sensibility than R.

Dec. 9, 1904: L. Pu. < R. Pu. L. T. Pu. < R. Pu. both physiologic. L. F. V. somewhat wider.

Dec. 12, 1904: Sympathectomy of superior ganglion o. d. (Dr. Stillman); chloroform narcosis. There was no change in pupil during operation. Pupil contracts with excision of ganglion. Some hours afterward R. T. < L. T. R. Pu. < L. Pu.

*Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Buller and Wood: "Poisoning by Wood Alcohol," The Journal A. M. A., Oct. 1, 8, 15, 22, 29, 1904.

[2] Koller in Med. Record, July 1, 1905, in a report on wood alcohol poisoning states the same observation, comparing this evanescent feature to *chorioiditis guttata.*

Jan. 7, 1905: T. normal o. u., R. a little < L. R. Pu. a little < L. Pu. Vision to patient seems slightly better," measurably stat. id. Ophthalmoscopically, stat. id. R. F. V. somewhat better.

Whether this improvement (real or apparent) has kept up, I am unable to say, having been on a trip abroad since.

Before entering on a discussion of the special points of interest in the foregoing history, I should like to express briefly my belief that wood alcohol amblyopia sets in at first through a defective local blood supply consequent on disturbances in the general circulation, as they find their clinical expression in weak pulse, slow respiration, sweating, coma, etc. This, at least, seems to me the inference to be drawn from those cases in which a very prompt great improvement of vision had taken place, after the first, often very sudden attack of blindnes, to be followed again by fresh failure of sight gradually leading to optic atrophy. As we know from the experiments of Pohl,[3] who found in the urine the maximum of formic acid, as the product of oxydation of wood alcohol, only after from three to four days, a cumulative effect of the poison takes place the reason, I take it, for the second (eventual) attack of grave amblyopia. The first attack of blindness would then be due anatomically to what Alfred Graefe[4] has described as *Ischæmia retinæ*. It would be of great interest, of course, if ophthalmoscopically contraction of blood vessels could be found during the attack.

Since the prognosis is so very bad, I should advise prompt performance of iridectomy or at least keratomy, in order to lower the intraocular pressure, in acordance with the good results obtained by thus increasing the intraocular circulation in Graefe's and Knapp's[5] cases of ischemia of the retina.

Neither do we know at present how to discriminate between cases in which the first attack of blindness might be overcome spontaneously, and those in which it will not, nor can anyone doubt the lowering effect on the optic nerve of the lessened blood supply, thus predisposing it for the specific effects of methyl alcohol.

If there is any foundation for the theoretic reasoning, I now beg to submit, in conclusion, that a course of procedure, as advocated, might also have a preventive effect in that regard. It is, of course, scarcely necessary to point out expressly that I did not perform iridectomy with any lingering thought for therapeutic effects as considerd so far. As those I have been able to interest sufficiently will have noticed, I had become convinced that in this case a simple glaucoma had developed. My reasons therefor are as follows:

1. The great similarity in both F V, which would be very unusual in optic atrophy pure and simple, and the missing parts being the inner ones.
2. Glaucomatous cupping of discs.
3. Insensibility of corneæ.
4. Indication of halos around papillæ.
5. History of pain (cf. above).

Neither would the absence of (observed) increase of tension necessarily be against the diagnosis of glaucoma simplex, nor am I, on the other hand, indeed, unmindful that the positive symptoms enumerated may not be absolutely convincing to every one, though they have tended to become so to me in this case from the extended observation. I should like to add that the late appearance of central color scotoma in R. E. seems to be rather in favor of the idea of a glaucomatous process complicating the pathologic changes in the optic nerves. Regarding the glaucomatous cupping, I have to add that Leber[6] states that exceptionally the atrophic excavation may assume a form that can not be differentiated from the pressure excavation in glaucoma simplex. Also Stelwag[7] makes the statement that in atrophy of the optic nerve the lamina cribrosa sometimes loses in resistance to such a degree as to recede (*nach hinten weichen*) and thus a deep cupping comes about, in exceptional cases an excavation even with steeper margins, such as develops constantly in glaumoca. Of greatest interest is the history given by Schmidt-Rimpler,[8] which supplies the anatomic proof for such views.

Without any other convincingly glaucomatous symptoms there was found in his case a typical pressure excavation in both eyes. Von Graefe's diagnosis was glaucoma simplex.

Before iridectomy, which had been decided on, could be done, the patient died of pneumonia. Postmortem examination showed both optic nerves throughout their whole course attenuated and flattened. Microscopically there was pronounced atrophy of the nervous fibers, which could be traced still beyond the chiasma into the tractus. The left *papilla optica* (hardened in Mueller's solution) was found to be pushed backward together with the lamina cribrosa. "Here, then, was an excavation showing absolutely the picture of glaucoma and yet being solely the result of the atrophy of the nerve."

Irrespective of the true place of T. P.'s case in reference to the excavation, it is of some value, I think, insofar as it is apt to make us ask whether so-called glaucoma simplex might not come about sometimes under normal intraocular tension if the optic nerve or lamina cribrosa has lessened resistancy. This question has repeatedly suggested itself to my mind when dealing with cases of glaucoma simplex in which there were absolutely no typically glaucomatous symptoms except a "pressure" excavation. In conversing about the point with my former chief, the late Professor Pflüger, whose mind was particularly trained to approach ophthalmologic questions from the standpoint of the physicist, he readily conceded its feasibility. Although Schmidt-Rimpler, as well as Leber,[9] refer in passing to the importance of the relative resisting power of the lamina cribrosa in the formation of a glaucomatous cupping, I know of only one reference in literature having a direct bearing on the point raised.

"Impossible, however, it is not that there are cases where, under the influence of the normal pressure, together with primary inflammation or weakness of opticus, the excavation takes place."[10]

The anatomic discoverer of the glaucomatous cupping of the disc, Heinrich Mueller, discusses in full in his classical treatise[11] the several possible modes of origin for the various forms of excavation of the disc, without, however, referring specifically to the formation of a glaucomatous cupping through normal pressure. He states that normal tension with lessened resistance may "modify the place of entrance." Mueller then refers to Donders as having verbally laid great stress on this point. Von Graefe[12] says "if we imagine the substance of the optic nerve loosened (*gelockert*) through some internal process the papilla will give way to the normal pressure in an anomalous way." Later it was Schweigger who in 1891 (cf. Horstmann) insisted that cupping of the disc to the margin may exist without the least demonstrable increase of tension, and that "such a condition might arise from any atrophic disease of the optic nerve when there was previously a physiologic cup." Neither Schweigger nor Horstmann[13] refer to the normal intraocular pressure as the direct cause for such "glaucomatous" cupping in apparently non-glaucomatous eyes.

[11] "Glaucom und Excavation der Sehnerven, in Gesammelte Schriften, etc.," edited by Otto Becker, Leipzig, 1872.

Schnabel's[14] views regarding true glaucomatous cupping as due to disintegration (Zerfall) of the optic fibers with formation of caverns, and "the glaucomatous excavation is one of these caverns"—are beside the point raised and are merely quoted for completeness' sake,[15] so are also Mueller's[11] conclusions that excavation —in general—might sometimes also be brought about by traction from without through shrinking exudate, etc.

Clearly the point is not of merely anatomic interest; if we could discriminate in glaucoma simplex without increase of tension between cases in which the "glaucomatous" cupping is due solely to simple atrophy, i. e., of fibrillæ and finer septa, and those in which it is the result directly of normal pressure on diseased or congenitally less resistant tissue, it would seem that the vexed question concerning the therapeutic effect of operative measures in glaucoma simplex would become clearer.

DISCUSSION.

Dr. E. V. L. Brown, Chicago, said that the pathogenesis of glaucomatous cupping in optic atrophy was much discussed at last year's meeting of the Vienna Ophthalmologic Society. The position was taken that this does occur in a great many cases without any tension whatever, and is due to the atrophy in the nerve head. Just back of it are found extensive areas of atrophic nerve fibers. Schmidt-Rimpler has also reported some observations on this point.

THE PHYSIOLOGIC ACTION OF DIONIN.*

WALTER HAMILTON SNYDER, M.D.
TOLEDO, OHIO.

Dionin is ethyl-morphin hydrochlorate, and was discovered by Grimaux ($C_{10} H_{23} NO_3 HCl + H_2O$). It is a white, odorless, bitter powder, soluble in water, 7 parts; in alcohol, 1.5; in syrup, 20. It is insoluble in ether and chloroform. The aqueous solution is neutral in reaction and keeps a long time. The general physiologic action is similar to that of morphin, but it is claimed that it is less toxic and does not produce nausea, constipation or habit. The respiratory and cardiac centers are unaffected. Applied to the eye, either as a solution or powder, it produces marked sneezing, vasodilation, edema, glandular excitation, burning and lachrymation and supposedly lymphatic extravasation, followed by analgesia, lasting from 2 to 48 hours. Wolffberg[1] of Breslau first used it in ophthalmic practice, but it was Darier's[2] report that brought it prominently before the profession.

The general literature on the drug is enormous, but I have been unable to find any experiments bearing on its actions on tissue and cells. I here cite my own:

Albino rabbit (medium size). Dionin in powder was placed in each eye in larger quantities than would be necessary if the eye was abnormal. The reaction was moderate, giving the usual appearance, only less in degree. The rabbit was killed. The globe and tissue were enucleated and placed in formalin 4 per cent. for 48 hours. Later sections from the cornea, through the ciliary region to the nerve were cut and then put through the usual technic of imbedding, sectioning, staining, etc. Control specimens were made from a normal rabbit's eye. I will here cite the findings:

Slide 1.—Magnification 210 diameters, section through cornea and ciliary region. (Fig. 1.) The lamellar spaces in substantia propria are dilated and edematous. The serous transudate involves the spaces at the junction of the cornea and ciliary region most. Is this not due to the dionin being placed directly over this region?

Slide 2.—Magnification 35 diameters. (Fig. 2.) This is same section under lower power and on close examination it is seen that the effect is greatest on the external side of the cornea and that the muscle is not affected, not even showing edema. Toward the sclera there is slight evidence of hyperemia.

Slide 3.—Magnification 210 diameters. (Fig. 3.) This is a control slide showing normal substantia propria. Compare this slide with No. 1 and see the effect dionin has had in elongating and widening the lymph spaces. In this section the lymph spaces are round, not widened or elongated as in the previous slide.

Slide 4.—Magnification 35 diameters. (Fig. 4.) This is the conjunctiva of a rabbit on whose eye dionin has been applied, suggesting the contention that the tissue changes are found only where there is tension; no edema or round cell infiltration can be found in this slide.

It might be well to introduce here an hypothesis to explain the clinical and microscopic action of dionin and to explain the clinical reports which, on comparison, at times are contradictory. Many slides were examined to arrive at certain conclusions and only the marked features photographed. From these I deduce that the action of dionin is purely local—greatest where the drug has actually rested. Its most marked action is in eyeballs in which the tension is increased, and I believe its entire action can be explained by saying that it has some disassociating action on the intercellular cement substance allowing a transudation of serum from a globe under pressure. That its analgesic action is to be explained by its lessening of tension and thus relieving pain, and by the well-known action of the derivatives of opium. It has been claimed for this drug that it is a lymphagogue, but opium lessens secretions, and the increased flow of apparent lymph, is not lymph, but serum which does not contain cells of any description. Lymph contains colorless blood cells and if the action of dionin was that of a lymphagogue, examination of the tissues would reveal the characteristic components of this fluid. I believe, therefore, that it is only a lymph stimulant secondarily; after the edema the fluid is absorbed as lymph, as it would be in edema from any cause. Careful examination of the slides reveals that locally where the drug is applied there is some change that permits fluid under pressure in the globe to pass through and into the tissue, causing edema and consequent lowering of tension. From these laboratory facts we should expect its action to be most marked in pathologic eyes, and, in these, greatest when the tension is highest. That its reaction subsequently is lessened rapidly, unless the tension is renewed, is a fact familiar to all who have used dionin.

[2] Ophth. Klin., No. vii, 1900.

I wish to enter into detail in a few findings not so generally admitted.

Darier[3] and Reber[4] have each reported cases of complete absorption of the lens and capsule during the use of dionin, and in a case of severe contusion of the eye without penetration this has occurred in my own practice.

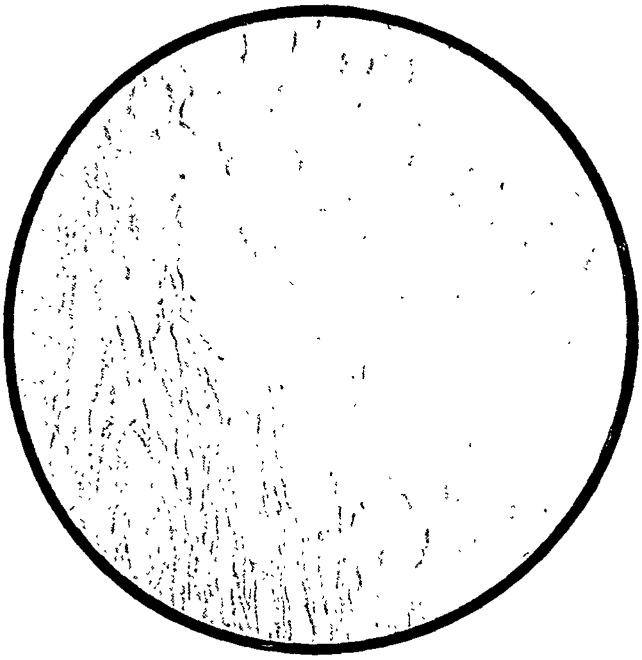

Fig. 1.—Magnified 210 diameters. Cornea and ciliary region showing the lamellar spaces in the substantia propria are dilated and edematous, especially at the corneal junction.

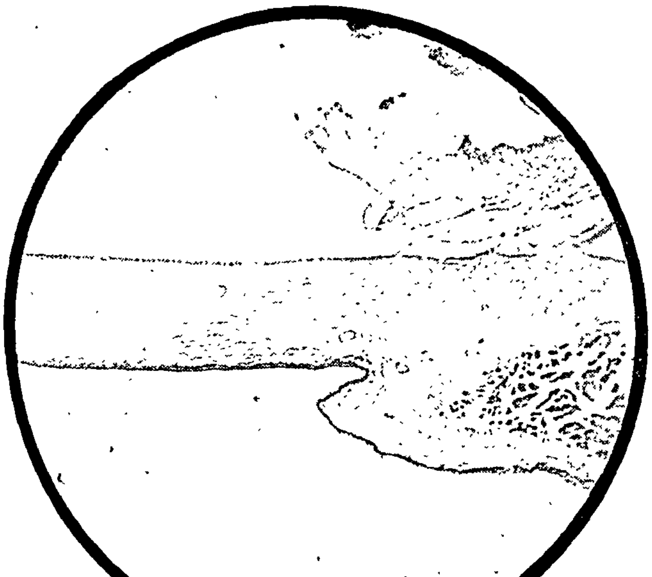

Fig. 2.—Magnified 35 diameters. Same section as in Fig. 1, through lower power. Note that effect on cornea is greatest on the external side. Muscle is not affected. Sclera is slightly hyperemic, showing how purely local is the action.

History.—Sept. 20, 1904, I first saw this patient and found hemorrhage in the anterior chamber, partially opaque lens—tension plus 2. Dionin and atropin were used daily. Each application would lessen the tension and it was used daily as a powder until December 28, when the fundus could be seen.

Condition.—Fluid was vitreous, the iris was dilated and maximum and drawn up in a mass in the inner upper quadrant.

Jan. 29, 1905; this iris had disappeared. Dr. Samuel D Risley has suggested as a possible explanation of the disappearance of the iris in this and similar cases that it inverts or "umbrellas" over the ciliary processes. Tension was normal, and vitreous fluid.

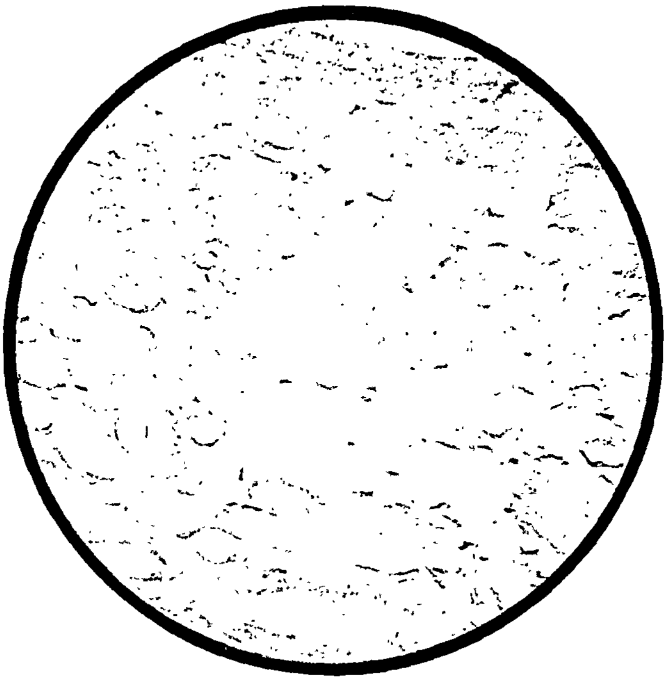

Fig. 3.—Magnified 210 diameters.—Control slides showing normal substantia propria. Compare with Fig. 1.

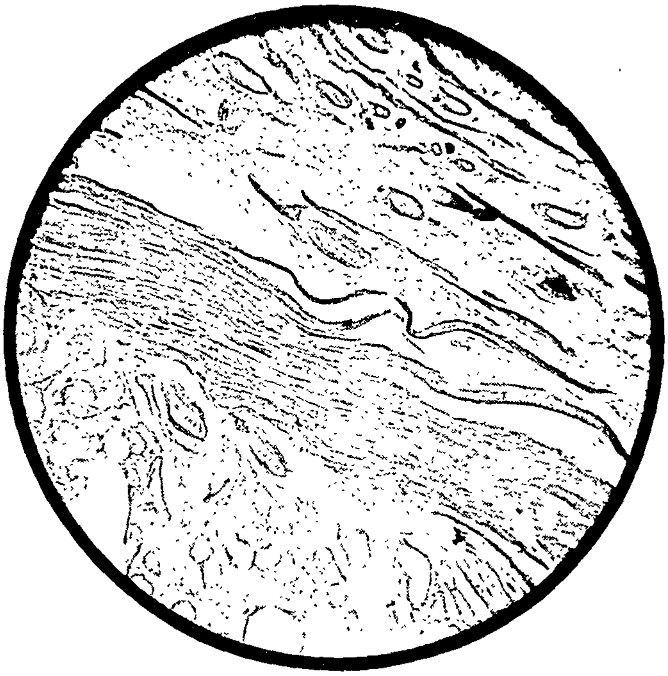

Fig. 4.—Magnified 35 diameters. Conjunctiva in fornix after dionin. No round cell infiltration or evidence of edema.

Later History.—April 2, 1905, a careful examination showed no iris, lens or capsule. With plus 8.00, combined with plus 4.00 cyl. axis 180, vision is 20/40 and a spherical plus 4 added gives Jaeger No. 1 at 17". The reaction to dionin was marked every day, something I have never seen before.

In iritis with adhesions and plus tension the use of dionin lessens the tension and permits absorption of the mydriatic, and prompt relief of pain and dilation of the pupil results. In corneal ulcers, especially the peripheral type, the repair process begins as soon as the ulcer is cleared. I have observed that the more recent the inflammation and the higher the tension the better the results obtained from its use.

[4] Reber: Ther. Gaz., Feb., 1904.

Konigstein agrees with this, as he states: "Dionin is almost completely abortive of parenchymatous keratitis if used in the earliest stages of the disease, but valueless in the late." Curiously enough, Graefe[5] gets "good results in vitreous opacities only when they are of long standing." Bourdeaux[6] and Batalow[7] think it is useful in the later stages of corneal opacity and that they clear up more quickly than without its use. In old cases I have not been so successful, but in recent cases my experience coincides with theirs. Central opacities of the cornea, especially if of long standing and with tension minus or normal are but slightly, if at all benefited in my experience. Von Arlt[8] has treated these patients "as long as 21 months with good results, especially in children." I have not persevered so long. Wolffberg[9] uses this drug in hemorrhagic glaucoma, which is seemingly logical. Bloch[10] states the greatest reaction occurs in pathologic condition. I should qualify this by adding "with increased tension." Sanz Blanco[11] "injects a 5 per cent. solution in intraocular hemorrhages with surprisingly good effects." "In one case the fundus could be seen in 5 days and in 30 days he (the patient) could read."

I have tried it in conjunctival hemorrhage with no reaction to speak of and no beneficial results over the ordinary treatment, evidently lacking the pressure factor. In beginning pannus I have cleared up the cornea and resisted permanent opacity more satisfactorily than with any previous treatment, the lid, of course, being treated for the cause.

In glaucoma, I prefer dionin to eserin, relief from pain being very marked, due, I think, to the mechanical relief from pressure. In old vitreous opacities I have had poor success, possibly because I have not used it long enough. I early abandoned the use of solutions and placed specks of the powder on two or three places on the cornea, especially finding the results better than solutions or applications in one place. This was when I thought the drug a lymph stimulant and is further proof that its action is as suggested in my hypothesis, because the action being purely local the larger number of places acted on the greater the relief from the tension. I wish here to express to W. J. Stone, B.S., M.D., my appreciation of his kindness in assisting me in the preparation of this paper.

DISCUSSION.

Dr. E. V. L. Brown, Chicago, referred to an article recently published on some work done in Breslau in which the author found that dionin had effect only on certain animals; not on all. The animals used were dogs, rabbits and cats, and the cats did not react in any way.

Dr. W. H. Snyder said that in rabbits the effect is very slight. It requires 100 times as much to get a reaction as in the human eye.

MEDICAL AFFAIRS IN THE HEART OF THE ARCTICS.

N. SENN, M.D.
Professor of Surgery, The University of Chicago; Professor of Surgery and Head of the Surgical Department Rush Medical College.
CHICAGO.

The geographic distribution of disease, the study of primitive races, of their climatic conditions, customs, habits and manner of living as etiologic influences, their methods employed in combatting disease and their resources in the treatment of accidents are subjects which can not fail to interest physicians who are concerned in the progress of their profession and the welfare of humanity the world over.

My vacation trip this summer brought me in touch with, and afforded me an excellent opportunity to study, one of the most interesting peoples in the world, the Eskimos of the far north, in the very heart of the Arctic region. These people are scattered in small settlements along the northern part of the west coast of Greenland, extending from Upernavik to Etah, a distance of about 600 miles. Etah is the most northern habitation of the Eskimos. It is in latitude 78° 40′ N. and is less than 700 miles from the North Pole. It is in the heart of the Arctic region, where so many fearless explorers have spent their long, dark winter night preliminary to the dash for the North Pole on foot and sledges over ice and hummocks of ice. It is here where so many hopes were shattered, where so much suffering was endured and where not a few brave sailors have found a premature grave.

Fig. 1.—Baffin Land Eskimo.

Fig. 2.—Eskimo family.

This unusual opportunity to visit the headquarters, the starting point of the Arctic explorers and the interesting people who live in this remote part of the inhabited world was presented to me through the courtesy of Commander Robert E. Peary, U. S. Navy, the famous explorer of the far North. Dr. Frederick Sohon of Washington, D. C., and myself were the only passengers on the *Erik*, which sailed from Sydney, Nova Scotia, Monday, July 17, with a cargo of coal for the Peary Arctic expedition now under way to the much-sought-for pole. Commander Peary and his crew sailed later from the same port on the *Roosevelt*, and it was understood that we should meet in North Star Bay on or before August 10. The *Roosevelt* met us in that place August 9, and proceeded at once to Etah. Commander Peary came on board the *Erik* to conduct the walrus hunt which was to take place in Murchison's Sound, between the two stations, and to pick up along the coast the Eskimos who were to form a part of the expedition. This trip, as well as the few days at Etah with the two ships lying side by side, gave rise to a good opportunity to become well acquainted with Commander Peary and to receive from him much valuable information concerning the Arctic region and its scanty population of Eskimos. Many of the members of the crews of both vessels were familiar with Arctic conditions and the customs and habits of the Eskimos. From these sources and the results of my own observations I have collected the material incorporated in this paper.

The real Eskimos inhabit the west coast of Greenland, north of the Danish colonies, beyond the limits of civilization. The Eskimos of the Cape York settlement were taken on board the *Roosevelt*. The *Erik* called at all the other settlements and the commander selected his material for the native part of the expedition as we went along, so that practically all of these came under my observation. The final weeding out of the undesirable took place at Etah before the *Roosevelt* sailed for the farthest North, at 3 a. m., Thursday, August 17. Twenty-one persons were left here to establish their winter quarters and to form the base of the expedition. The *Erik* left Etah Wednesday, August 23, with orders to call at Godhavn on the return voyage to St. Johns, Newfoundland, where we arrived September 5.

THE REAL ESKIMOS.

The Eskimos within the limits of civilization, that is, those living in the Danish colonies and settlements, in Baffin Land and Labrador, have lost their original type and have largely abandoned their primitive way of living. Intermarriage with Europeans and Americans for more than a century has resulted in a mixture of races which has either completely effaced the typical Eskimo physiognomy or has, at any rate, modified it so much that it has become almost unrecognizable (Fig. 1). Many of the Eskimos in Danish Greenland would

Fig. 3.—Eskimo woman.

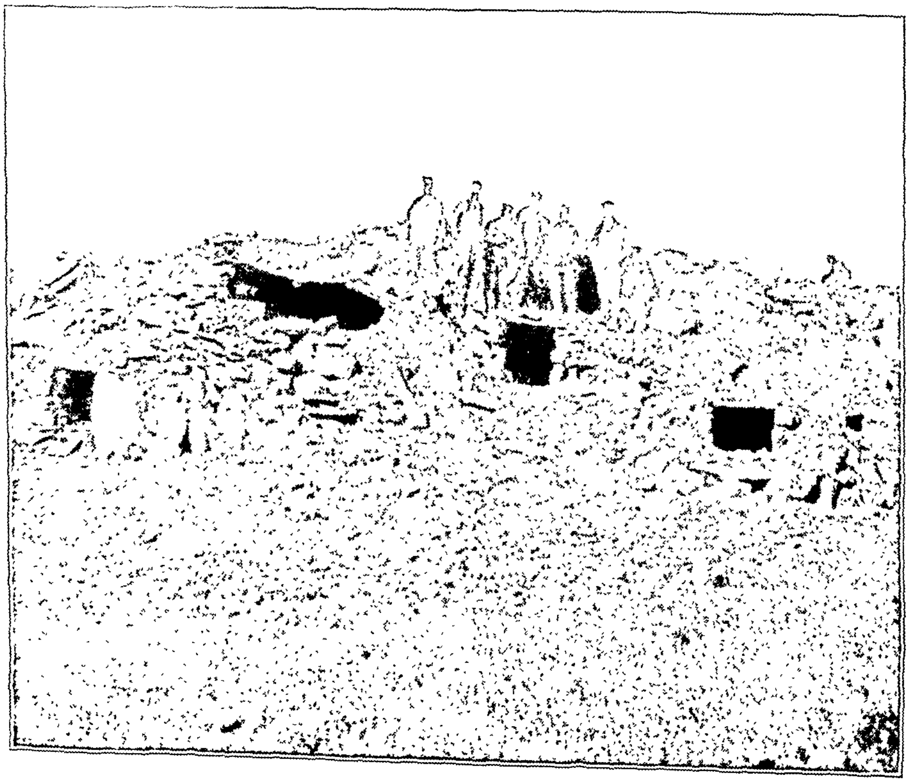

Fig. 4.—Igloo (Eskimo stone hut).

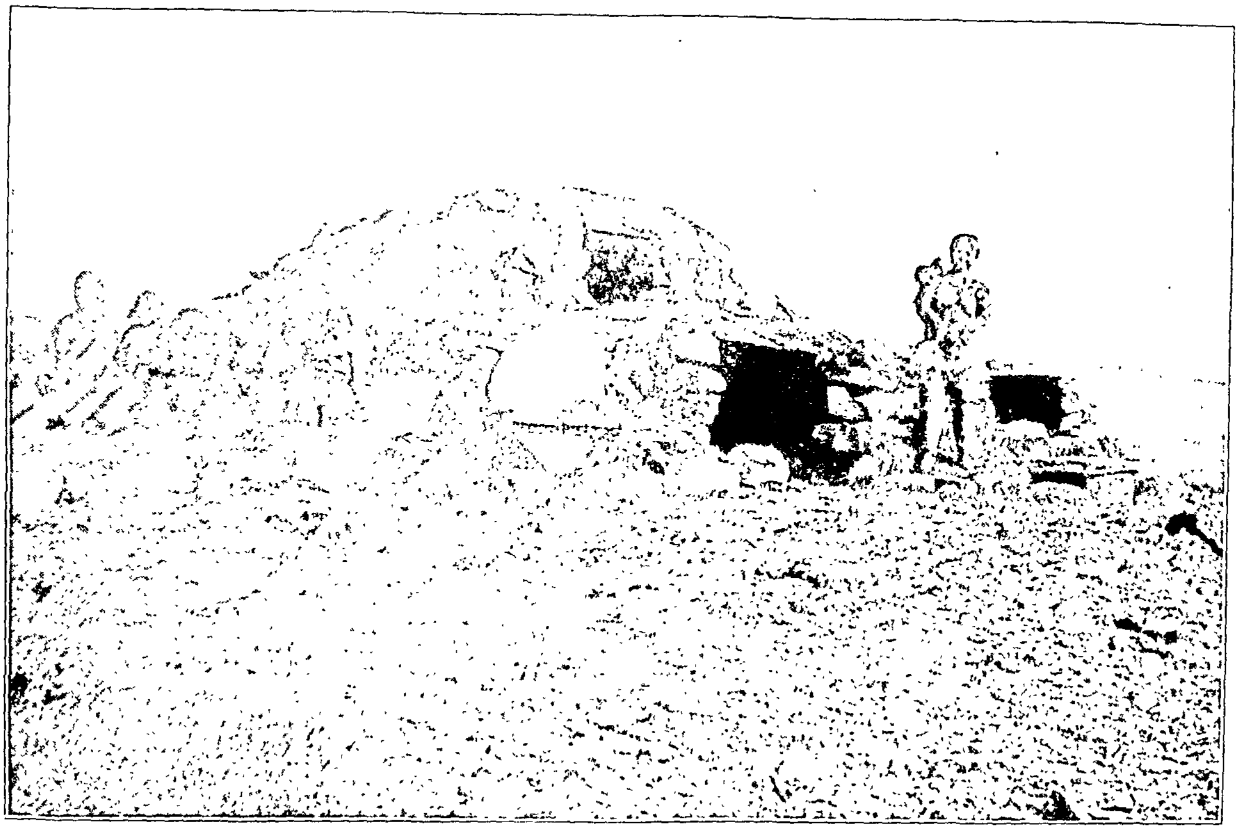

Fig. 5.—Igloo.

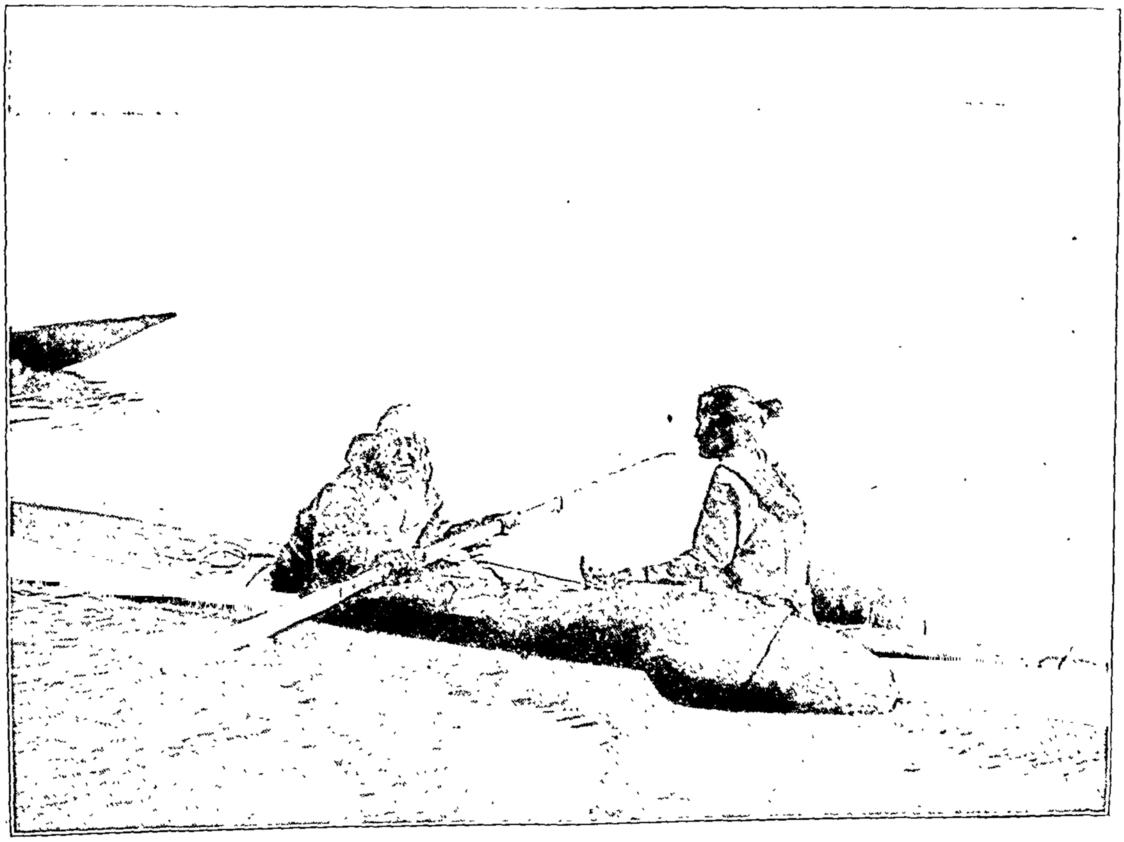

Fig. 6.—Eskimo man and woman in a kayak.

be taken anywhere for Danes or Scandinavians, so far as their appearance is concerned, rather than for natives of the Arctics. The round, full, flat face has, in the course of many generations, been moulded into a face characteristic of the people inhabiting the countries of North Europe. Blond hair and blue eyes, something never seen in a genuine Eskimo, are by no means uncommon here. In Labrador and Baffin Sound similar changes have occurred in consequence of race mixture. The Eskimos, like other primitive races when brought in contact with foreigners, have a longing to adopt their dress and manner of life, hence those who have lived among them have adopted habits and customs entirely different from those of the untutored, genuine Eskimos.

The real Eskimos are now only to be found in the heart of the Arctic region along the strip of the coast of Greenland that I have indicated. These people live in isolation and what little communication they have with the outside world through polar expeditions has made little if any impression on their manner of living (Fig. 2).

Commander Peary has been among these people a good deal of his time for the last 14 years. He knows them well, can call them by their names and has their unlimited confidence. He knows the history of all of them who are more than 2 years of age. He speaks their language and is perfectly familiar with their habits of life and the few diseases to which they have been subject since he first visited them. He is a very careful observer and his statements can be relied on.

Although the Eskimo race is a distinct one and has little in common with the Indians of North and South America, there can be no doubt of its Asiatic origin. The Eskimos are below average size, thick-set, legs short, face flat, malar bones and cheeks very prominent, well-shaped nose, although in many of them the bridge is somewhat depressed; eyes universally brown, lower jaw well developed, teeth regular, pearly white and in perfect condition; hair straight, coal-black; beard scanty, as well as the eyebrows and eyelashes; eye slit slightly narrowed, not oblique; forehead full and only slightly receding, mouth large, lips thin and fine-cut, color of skin dusky, cheeks florid with a copper tinge, hands and feet small, even delicate. The women are much smaller than the men, many of them being not more than four feet in height. Their garments are made of fur—bearskin for trousers, which are made long for men, short for women; the former wear short, the latter long sealskin boots (Figs. 2 and 3). The coat, with hood, is made of seal or foxskin, the former for summer and the latter for winter wear. Bird skins and the fur of the Arctic hare are worn for underclothing. The native dress is admirably adapted for the climate in which these people live, and Commander Peary has adopted it for himself and wears it summer and winter.

The Eskimos are the filthiest people in the world. They never wash, not even the face and hands. The smell of the fur clothing and secretions of the skin are productive of a stench about their persons and especially in their igloos and tents that is characteristic and at first very obnoxious to the uninitiated. During winter these people live in huts (igloos) (Figs. 4 and 5), of stone or ice; in summer in tents of sealskin. Furs are used for the common family bed and each occupant, from father to babe, strips completely before retiring. They do not marry in the sense in which we use this word, but mate like animals for convenient periods of time, which may be for life, for a year, or only for a hunting trip of a few days. Exchange of mates for an indefinite time is of common occurrence.

These people are all children, contented, peaceable, honest and hospitable; they are without a ruler and without any ambition for fame or power—an ideal socialistic community where property is held in common, politics unknown, and where all are on the same social plane.

They subsist almost exclusively on a raw animal diet, which explains the absence of a number of diseases that are common among the civilized people. Salt water contains iodin, and all animals living in it and all animals which live on sea food absorb more or less of this fickle chemical substance. None of these people has ever suffered from scurvy, which was such a common affection among the crews of the early polar expeditions and which occasionally afflicts the Eskimos who consume more cooked than raw animal food. Peary has profited by this observation, and places great importance in supplying his crew with fresh meat, and has never seen a case of scurvy among them. He has found by experience that lime juice, which formerly enjoyed such an enviable reputation as an antiscorbutic, is not only useless but harmful. Taken in the Arctic region, it acts as a cathartic and becomes distasteful to those who have used it.

The iodized raw animal food also explains satisfactorily the absence of enlarged tonsils, cervical lymphatic glands and goiter. I examined the throats and necks of many Eskimos and found the tonsils and thyroid glands in all of these in a markedly atrophic condition, and in none of them, except in two syphilitics, were there any palpable cervical lymphatics. The perfect, splendid teeth and strong lower jaw are the anatomic points of the carnivorous diet. I examined the mouths of several persons between 60 and 70 years of age and found every tooth in place and firm but ground away by long usage almost to the level of the healthy gums. The vocation of the Eskimos, both men and women, requires very little use of the legs, consequently they have suffered in length while, on the other hand, paddling of the kayak (Fig. 6), throwing of the harpoon and lance and handling of the dog-whip have resulted in the course of centuries in an unusual development of arms and chest.

Although I have no positive information on the subject, I am satisfied that the exclusion of all vegetable food from the diet has shortened the gastrointestinal canal, that the appendix, if present at all, is in the most rudimentary form and that the glands concerned in the digestion of starchy food have become atrophic, while those whose secretion is needed for the digestion of meat and the emulsification of the fats are hypertrophic. The stomach digestion of these people is something wonderful. Indigestion is about as infrequent as in the dog—in fact I believe there is the closest analogy between the anatomy and physiology of the organs of digestion of the Eskimo and the only domestic animal with which he is familiar, the dog. Commander Peary and a number of the men of both crews, who have seen much of Eskimo life, can not remember of ever having seen a case of chronic indigestion, peritonitis, or intestinal obstruction. Hair and fragments of bone taken with the food by the dog occasionally produce peritonitis in this animal, but these mechanical causes for such affections of the intestinal canal are excluded from the diet of the Eskimo. We would naturally conclude that an exclusi

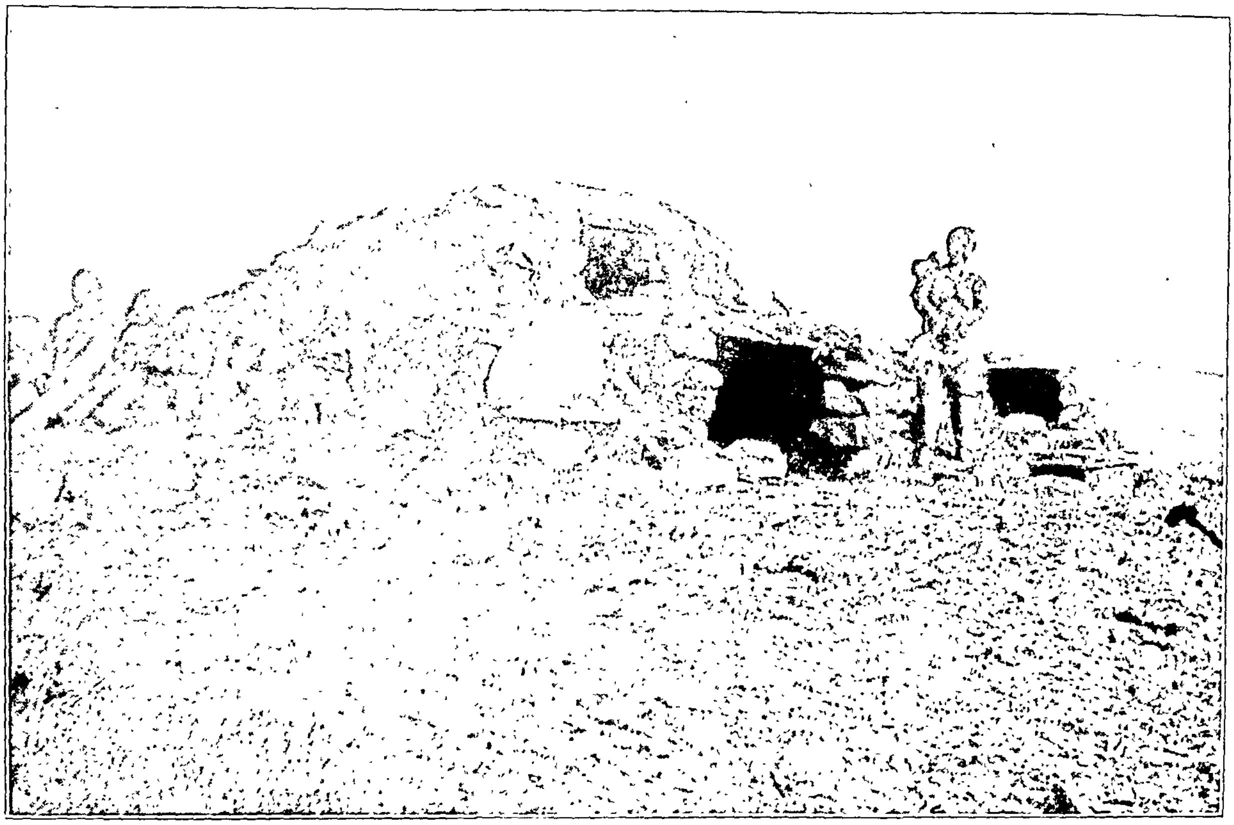

Fig. 5.—Igloo.

be taken anywhere for Danes or Scandinavians, so far as their appearance is concerned, rather than for natives of the Arctics. The round, full, flat face has, in the course of many generations, been moulded into a face characteristic of the people inhabiting the countries of North Europe. Blond hair and blue eyes, something never seen in a genuine Eskimo, are by no means uncommon here. In Labrador and Baffin Sound similar changes have occurred in consequence of race mixture. The Eskimos, like other primitive races when brought in contact with foreigners, have a longing to adopt their dress and manner of life, hence those who have lived among them have adopted habits and customs entirely different from those of the untutored, genuine Eskimos.

The real Eskimos are now only to be found in the heart of the Arctic region along the strip of the coast of Greenland that I have indicated. These people live in isolation and what little communication they have with the outside world through polar expeditions has made little if any impression on their manner of living (Fig. 2).

Commander Peary has been among these people a good deal of his time for the last 14 years. He knows them well, can call them by their names and has their unlimited confidence. He knows the history of all of them who are more than 2 years of age. He speaks their language and is perfectly familiar with their habits of life and the few diseases to which they have been subject since he first visited them. He is a very careful observer and his statements can be relied on.

Although the Eskimo race is a distinct one and has little in common with the Indians of North and South America, there can be no doubt of its Asiatic origin. The Eskimos are below average size, thick-set, legs short, face flat, malar bones and cheeks very prominent, well-shaped nose, although in many of them the bridge is somewhat depressed; eyes universally brown, lower jaw well developed, teeth regular, pearly white and in perfect condition; hair straight, coal-black; beard scanty, as well as the eyebrows and eyelashes; eye slit slightly narrowed, not oblique; forehead full and only slightly receding, mouth large, lips thin and fine-cut, color of skin dusky, cheeks florid with a copper tinge, hands and feet small, even delicate. The women are much smaller than the men, many of them being not more than four feet in height. Their garments are made of fur—bearskin for trousers, which are made long for men, short for women; the former wear short, the latter long sealskin boots (Figs. 2 and 3). The coat, with hood, is made of seal or foxskin, the former for summer and the latter for winter wear. Bird skins and the fur of the Arctic hare are worn for underclothing. The native dress is admirably adapted for the climate in which these people live, and Commander Peary has adopted it for himself and wears it summer and winter.

The Eskimos are the filthiest people in the world. They never wash, not even the face and hands. The smell of the fur clothing and secretions of the skin are productive of a stench about their persons and especially in their igloos and tents that is characteristic and at first very obnoxious to the uninitiated. During winter these people live in huts (igloos) (Figs. 4 and 5), of stone or ice; in summer in tents of sealskin. Furs are used for the common family bed and each occupant, from father to babe, strips completely before retiring. They do not marry in the sense in which we use this word, but mate like animals for convenient periods of time, which may be for life, for a year, or only for a hunting trip of a few days. Exchange of mates for an indefinite time is of common occurrence.

These people are all children, contented, peaceable, honest and hospitable; they are without a ruler and without any ambition for fame or power—an ideal socialistic community where property is held in common, politics unknown, and where all are on the same social plane.

They subsist almost exclusively on a raw animal diet, which explains the absence of a number of diseases that are common among the civilized people. Salt water contains iodin, and all animals living in it and all animals which live on sea food absorb more or less of this fickle chemical substance. None of these people has ever suffered from scurvy, which was such a common affection among the crews of the early polar expeditions and which occasionally afflicts the Eskimos who consume more cooked than raw animal food. Peary has profited by this observation, and places great importance in supplying his crew with fresh meat, and has never seen a case of scurvy among them. He has found by experience that lime juice, which formerly enjoyed such an enviable reputation as an antiscorbutic, is not only useless but harmful. Taken in the Arctic region, it acts as a cathartic and becomes distasteful to those who have used it.

The iodized raw animal food also explains satisfactorily the absence of enlarged tonsils, cervical lymphatic glands and goiter. I examined the throats and necks of many Eskimos and found the tonsils and thyroid glands in all of these in a markedly atrophic condition, and in none of them, except in two syphilitics, were there any palpable cervical lymphatics. The perfect, splendid teeth and strong lower jaw are the anatomic points of the carnivorous diet. I examined the mouths of several persons between 60 and 70 years of age and found every tooth in place and firm but ground away by long usage almost to the level of the healthy gums. The vocation of the Eskimos, both men and women, requires very little use of the legs, consequently they have suffered in length while, on the other hand, paddling of the kayak (Fig. 6), throwing of the harpoon and lance and handling of the dog-whip have resulted in the course of centuries in an unusual development of arms and chest.

Although I have no positive information on the subject, I am satisfied that the exclusion of all vegetable food from the diet has shortened the gastrointestinal canal, that the appendix, if present at all, is in the most rudimentary form and that the glands concerned in the digestion of starchy food have become atrophic, while those whose secretion is needed for the digestion of meat and the emulsification of the fats are hypertrophic. The stomach digestion of these people is something wonderful. Indigestion is about as infrequent as in the dog—in fact I believe there is the closest analogy between the anatomy and physiology of the organs of digestion of the Eskimo and the only domestic animal with which he is familiar, the dog. Commander Peary and a number of the men of both crews, who have seen much of Eskimo life, can not remember of ever having seen a case of chronic indigestion, peritonitis, or intestinal obstruction. Hair and fragments of bone taken with the food by the dog occasionally produce peritonitis in this animal, but these mechanical causes for such affections of the intestinal canal are excluded from the diet of the Eskimo. We would naturally conclude that an exc animal diet would cause constipation and a uric acid diathesis with a long train of their remote consequences —headache, insomnia, skin eruptions, gout, rheumatism, etc.—but this is not the case. The large percentage of oil contained in their diet acts as a gentle laxative and protects them against a multitude of ailments which form the major part of the diseases with which the general practitioner has to deal. The Eskimo can eat with relish and without any ill consequences old, stinking blubber that would turn the stomach of a crow and that if eaten by a white man, if he could retain it, would kill him by producing ptomain poisoning.

The skin of the Eskimo, covered with filth and vermin, is remarkable for its smoothness and immunity to skin diseases. The only skin eruptions I have seen among the large number of Eskimos of all ages I examined was a patch of psoriasis over the posterior surface of the elbow of a syphilitic, and a small pustular eruption affecting one ala of the nose in an infant suffering from a nasal catarrh. The very fact that these people fear and avoid the external use of water may account for their freedom from diseases of the skin. The exposure of the hair to the midnight sun for more than three months of the year and the wearing of a loose hood of fur during the winter favors hair growth. Baldness is unknown here and even Time finds it difficult to bleach the coal-black hair and beard. Men and women of 60 and more years show only here and there a gray streak in the luxuriant hair never touched by the comb.

The special senses, except that of smell, are very keen and old age appears to have little if any influence in diminishing the acuteness of sight and hearing. The acuteness of vision for near and distant objects of these people is something that will astonish the visitor. I became aware of this on my hunting trips under the guidance of Eskimos. They could see a hare or a bird far beyond the reach of my vision and could calculate the distance with an infallible accuracy, something no one is capable of doing who is not habituated to the rarity of the atmosphere of the Arctic region.

DISEASES.

It would take much less space to enumerate the diseases to which the Eskimos are subject than to name se to which they appear to be almost immune so long they live in their own climate and do not deviate m their customary habits of life.

Tuberculosis in any form is unknown among the Esıos in the heart of the Arctic region. I heard no hisical cough, saw no emaciated forms nor hectic ısh; no cases of lupus, glandular, joint or bone tuberculosis and no cripples except the man who lost part of one foot from frost bite. Experience, however, has shown that as soon as these people are brought to the United States they contract pulmonary tuberculosis of the most virulent form and succumb to the disease in a few months. Of six persons brought to the American Museum of Natural History in New York all contracted the disease and in less than six months four of them were dead, one returned and recovered and one remained in New York still suffering from a more lingering form of the disease. The one who returned to his Arctic home and resumed his former manner of living made a very speedy and permanent recovery, a strong argument in favor of the Arctic region as a summer resort for tubercular patients. The focus of infection created by this patient in the settlement to which he came and where he has since lived has proved harmless during the eight years that have expired since his return.

Rheumatism is one of the most prevalent diseases among the Eskimos. At the North Star Bay settlement I found a man about 35 years of age in one of the tents completely crippled by this disease which, according to Peary, commenced twelve years before. He was lying helpless on his reindeer skin, with every large joint of all the limbs contracted and stiff. The left elbow was swollen, painful and exquisitely tender to the slightest touch. He was smoking and appeared to be not in the least concerned about his helpless condition, as, according to the prevailing custom among the natives, the tribe provided him and his family with food and clothing. Lumbago and sciatica frequently affect in this climate the crews of expeditions and whalers.

Venereal diseases were introduced here by the whites and have become widely diffused throughout the native population, owing to the unrestrained, promiscuous intercourse practiced everywhere. Syphilis pursues a very mild course in the natives. None of the terrible ravages of the tertiary form of this disease, with which we are so familiar, are seen here. I have no doubt that the iodin contained in their food furnishes a satisfactory explanation for this. A well-known Eskimo is known to have contracted the disease eight years ago. He has had no treatment of any kind and is now in perfect health and the father of several healthy, vigorous children. I examined a boy about 15 years of age who was then the subject of secondary lesions. I found mucus patches on the inner surface of the lower lip, general lymphatic hyperplasia but no cutaneous eruptions. The severest case of tertiary syphilis I have seen was in the case of a man about 50 years of age whose woman was infected by a member of an Arctic crew some eight or ten years ago. One of her children of a corresponding age, a girl, is a half-caste, pale and delicate. This man bore all the marks of a syphilitic cachexia; his arteries were atheromatous, a patch of psoriasis affected the posterior aspect of one of the elbow joints and the cervical and epitrochlear glands were very much enlarged. I did not see a single case of saddle-nose, of gumma, periostitis, Hutchinson's teeth or syphilitic alopecia. These facts prove conclusively that syphilis among these people pursues an unusually benign course, for which we must give credit to their liberally iodized sea food. Gonorrhea seems to follow the same benign course. Careful inquiry and abundant testimony from reliable sources combine to show that stricture, orchitis and cystitis do not exist. I questioned Commander Peary and Mr. Henson, his main man, who have spent seven winters among these natives, with special reference to the existence of urinary difficulties among old men. From their accounts it appears that prostatic obstruction does not exist, as they have seen many of the men urinate, and noticed that the stream was large and strong. The sexual life of these people and the iodized food may account for the absence of senile prostatic hypertrophy and its consequences, urinary obstruction and eventually renal disease. I saw one case of gonorrheal ophthalmia of a mild form in an adult and complete corneal opacity of one eye in the case of a young girl, caused undoubtedly by this disease. One man and a woman had each lost an eye from traumatic causes.

Winter Anemia.—The long winter, with its attendant darkness and long confinement in the small, badly-ventilated huts, to which is often added a lack of sufficient food, is productive of anemia and its results, debility, insomnia and nervousness. Commander Peary anticipated this change in the conditions of the blood and the defective nutrition and guards against them by keeping his crew and the Eskimos as much as possible out of doors and busy, and supplying them with an abundance of fresh meat. He has found this prophylactic treatment equally effective with both contingents of his expedition. The general lack of nutrition during the long winter night is best shown in the case of his little daughter. She was born in Bowdoin Bay, an arm of Inglefield Gulf, in September. Her weight and size remained the same until the sun made his appearance and she was taken out daily in the open air in a dog sledge, when she commenced to grow rapidly and the blush of health and vigor appeared in her face. Nature takes a long rest in the Arctic region and this affects animal as well as vegetable life; the former comes to a standstill, the latter, for the time being, completely suspended. With the appearance of the sun reanimation takes place, which reaches its maximum during the long and uninterrupted reign of the midnight sun. The effect of the midnight sun on vegetation in the Arctic region is remarkable. What takes place in plant growth with us in months is accomplished here in as many weeks. In four to six weeks the flowering plants bud, blossom and mature their seed. Animal life during this time receives the same stimulating benefit from the sun.

Affections of the Nervous System.—Insanity among the Eskimos is unknown. As these people have never been given an opportunity to indulge in alcoholic drinks they are free from all affections due to alcoholism. Smoking is a new vice with them which crept in a few years ago, but as the supply of tobacco is irregular and most of the time scanty or entirely lacking, it has so far produced no ill results. The natives, however, have a strong liking for the weed and when the supply of tobacco warrants it, young and old enjoy the pipe, which makes its rounds if only one is at their disposal. I have seen children on their mothers' backs do their good share in burning up the contents of a pipe. The same causes which combine in the causation of winter anemia result occasionally in producing a nervous condition closely allied to, if not identical with, hysteria. Peary in 1900, on his trip to the northeast coast of Greenland, witnessed this condition and describes it as follows: "When we were drinking our tea one of the younger Eskimos fell in a fit and the others became hysterical. I felt a peculiar dizzy sensation myself. Recognizing the effect of our alcohol cooker in the close atmosphere of the igloo, with every aperture sealed by the newly-fallen snow, I hurriedly kicked out the door and a portion of the front wall. This relieved matters, and I sent three of the Eskimos outside to get the benefit of the fresh air, while I took the two worst ones in hand personally, and finally succeeded in quieting them down. After this they were 'ankooting' all day. The open water ahead of us, the groaning pack beside us, the bad weather and the, to them, mysterious attack of the morning, had combined to put them all in a very timid and unsteady frame of mind" (*McClure's Magazine*).

It is well known that the long winter, with its depressing effects on body and mind, often disturbs the equilibrium of the otherwise well-balanced nervous system of the natives. But the nervousness, or call it hysteria, never becomes chronic, and disappears under more favorable climatic or dietetic conditions. A similar train of nervous symptoms has not infrequently been observed in members of Arctic expeditions who wintered here and the depression in one or two cases has been so grave as to induce the poor sufferers to seek relief by committing suicide. I could not learn of a single case of epilepsy, chorea or apoplexy.

(*To be continued.*)

IMMUNITY.

CHAPTER XXXI (Concluded).

OIDIOMYCOSIS.

Under the name of oidiomycosis may be included first, the diseases usually called blastomycosis, saccharomycosis and coccidioidal infection, and second, thrush, whether local or generalized.

In 1894 Gilchrist described a skin disease, which has since been known as blastomycetic dermatitis, or blastomycosis or oidiomycosis of the skin. From a second case he cultivated a fungus which at first he was inclined to consider as an oidium but later called a blastomyces. Since that time many similar cases, especially in Chicago and the adjacent territory, have been discovered and reported by Wells, Hektoen, Hessler, Hyde and Montgomery, Ricketts and others. In many instances the specific fungi have been cultivated.

Systemic Oidiomycosis.

Further investigations by Rixford and Gilchrist, Busse, Ophüls and Moffit, Hyde and Montgomery and others have brought to light the existence of systemic infections by fungi which resemble closely those found in blastomycetic dermatitis, and, in fact, cases in which the infection primarily was limited to the skin have gone on to generalized infection. The *Saccharomycosis hominis* of Busse and of Curtis, blastomycetic dermatitis, generalized blastomycosis, and about a dozen cases in California which at one time were considered to be of protozoön etiology (Rixford and Gilchrist), are closely related or identical processes which have as their cause a group of fungi, the individual strains of which may show considerable differences.

Histology.

The skin infection usually appears as a coarse warty and ulcerative lesion, in which the large papillæ and cutaneous areola are beset with minute abscesses; the process extends gradually and eventually may involve large areas. Histologically, the tissue shows an enormous epithelial hyperplasia with intraepithelial abscesses, and a richly cellular, granulomatous condition of the subepithelial tissue, in which giant cells and small abscesses are found. When the disease is systemic, various internal organs, especially the lungs, spleen and kidneys, are the seats of abscesses and nodules which contain the parasites in immense numbers. The lungs show lobular or more extensive consolidation.

Nature of Fungi.

In those cases usually described as blastomycetic dermatitis or systemic blastomycosis, the fungus proliferates by budding, and is found chiefly in the intraepithelial and subcutaneous abscesses, and in the granulation tissue and nodules of internal organs. Its appearance in culture media and its biologic properties are subject to considerable variations, at one time growing as a mold, at another time more like the typical oidium, and again resembling some form of yeast. Ricketts considers that the genus oidium is sufficiently broad to include all the types which have been described, and that blastomyces is too narrow. The organisms which have been cultivated from the cases in California grow as molds, and they differ from those described by Gilchrist, Hektoen, Ricketts and others, in that they form endospores and apparently do not bud in the tissues of the host (Ophüls, Wolbach). Ophüls calls this parasite *Oidium coccidoides*, agreeing with Ricketts as to the generic character of the group.

Infection Atria.

The skin infection occasionally follows slight traumatism while in other instances no predisposing condition is known by the patient. The occurrence of cutaneous lesions in crops has been noted, and suggests that in some instances they may originate as embolic foci from a pulmonary lesion which later heals or becomes latent. In the systemic infection the primary lesion appears to be in the lungs in most cases, from which the blood and other organs, including the skin, may be invaded. Pulmonary oidiomycosis simulates pulmonary tuberculosis. In extensive involvement of the lungs the organisms may be demonstrated in the sputum. At present nothing is known concerning immunity to these infections.

Fungi of the type found in cutaneous or generalized oidiomycosis are widely distributed in nature, and the comparative rarity of the disease suggests that their virulence usually is low, or that susceptibility is rare; perhaps both conditions exist.

THRUSH.

Thrush is one form of oidiomycosis and is of particular interest because of the early date at which its parasitic nature was recognized. Langenbeck and Berg, in 1839 and 1841, are cited as the discoverers of the fungus, and they reproduced the disease by inoculations with fragments of the membrane. The parasite was studied a little later by Gruby, Robin and others and the latter gave it the name of *Oidium albicans.* Grawitz obtained it in pure culture in 1877 and demonstrated its pathogenicity for dogs and rabbits.

Cultures obtained from different cases show differences in size, morphology, chemical activities and methods of proliferation, although the variations are hardly so wide as those found in the organisms cultivated from cases of "blastomycosis."

Systemic Infection.

Although thrush usually is considered a rather harmless affection, Virchow long ago showed that its filaments may penetrate the submucous tissues and even into the blood vessels. In rare instances systemic infection, with abscesses in the brain, kidney and spleen, or with consolidation of the lungs, have been noted; in these cases the conditions resemble those found in systemic "blastomycosis."

The healthy person has little or no susceptibility to thrush, although a few cases of infection have been noted in individuals who were otherwise normal. Customarily it attacks only those who are in a low state of vitality, as poorly nourished children or those in advanced age, or those whose resistance is much lowered by some other disease (typhoid, diabetes, etc.).

Phagocytosis and Immunity.

Phagocytosis of yeast and oidium-like cells takes place when they are placed in the abdominal cavity of experiment animals (guinea-pigs). A number of leucocytes may fuse to form a plasmodial mass around one or more of the parasitic cells. Roger and Noisette caused an increase in the resistance of rabbits to thrush infection by the intravenous injection of small doses of the parasite. According to Noisette, an immune serum agglutinates only the strain used in the immunization.

Infections of other animals (horses, cattle) by oidium-like organisms, the trichophyton and other fungi which cause superficial diseases in the skin of man, and other fungi (aspergillus, mucor), which occasionally are pathogenic for man, will not be discussed.

CHAPTER XXXII.

ANTHRAX.

From the standpoint of infection and immunity anthrax is of particular interest. It is the first disease of which the bacterial etiology was proved and in which the specific microbe was used in pure culture for the production of artificial immunity (vaccination).

Anthrax is particularly a disease of cattle and sheep, and it prevails in certain European countries, especially Russia, in Australia and in South America. It does not occur extensively in this country. Definite regions are at times heavily infected, and it is in such localities that the disease is most frequently transmitted to man.

Bacillus Anthracis.

As early as 1850 Rayer and Devaine, also Pollender, had discovered the presence of small rods and filaments in the blood of animals which had died of anthrax, and the work of Koch, Pasteur and others soon established that this rod, the anthrax bacillus, is the cause of anthrax. The discovery of Koch that the bacilus forms extremely resistant spores, explained the persistance with which the disease infects particular localities.

Spores.

The anthrax bacillus is a fairly large organism, is rod-shaped, non-motile and grows with characteristic appearances on various culture media. With the proper temperature and culture medium, and in the presence of free oxygen, the formation of spores begins after about twenty-four hours of growth. Their evolution is complete in from one to two days, and eventually the protoplasm of the cells disintegrates and the spores are set free. Spores are not formed in the body of an infected animal. Anthrax prevails especially in the spring and summer, and the bacilli as they are discharged with the urine or feces find in the open air and warm temperature conditions which are favorable for the formation of spores. Spore formation is not essential, however, for the continued life of the organism; at high temperatures (42 C.), and in the presence of minute amounts of acids and alkalis or of carbolic acid, strains may be so altered that they lose permanently the ability to produce spores. Under favorable conditions the spores germinate completely in from three-quarters to one and one-half hours (Grethe) by a process in which they lose their refractive appearance and assume first an oval and then a rod shape. In the body a capsule surrounds the bacillus, and it grows singly or in very short chains; in culture media it is very difficult to obtain capsules. The long threads which appear in culture media, especially bouillon, are not found in infected animals.

Resistance and Virulence.

The bacillus itself shows no unusual resistance, but its spores are more resistant than those of any other pathogenic bacterium. When dried on a thread they have been known to live for from ten to twelve years. Corrosive sublimate (1-2,000) kills them in forty minutes (Fraenkel), and direct sunlight in about 100 hours (Momont). *Bacillus pyocyaneus.* streptococci, staphylococci and the bacillus of Friedlander are said to antagonize its growth.

The anthrax bacillus is remarkable for its infectiousness. A twenty-millionth of a loop of a virulent culture will cause a fatal infection in mice, guinea-pigs and rabbits, when given subcutaneously. A systemic infection may be produced by feeding the spores or causing animals to inhale them. The gastric juice is able to kill the bacilli, but not the spores, which germinate after they reach the intestines.

The organism is distributed by the excretions of diseased animals, and after their death the adjacent soil becomes heavily infected by the discharges which escape from the intestines and bladder. In this situation the bacilli pass into the sporing stage, in which they remain viable and virulent for a long time.

Infection Atria.

The infection of herds usually is accomplished by the ingestion of spores which have been distributed in this way, the spores germinating after they have reached the intestines as described above. The disease may be primary in the skin in the form of malignant pustule. In man malignant pustule is the commonest type of infection, occurring especially among those who have to do with cattle and sheep. The bacilli, however, may gain entrance through the lungs as in the so-called "wool-sorter's" disease, which is caused by the inhalation of infected dust from the raw material.

The generalized infection in all animals is rapidly fatal (one to three days), and the occurrence of death is sometimes so sudden as to be called apoplectiform; in man the mortality is about 50 per cent. Malignant pustule runs a more favorable course.

Toxin!

The general infections are marked by symptoms of intense intoxication and acute degenerative changes are produced in the parenchymatous organs. Massive numbers of the bacilli are found in the blood. Neither a soluble toxin nor an endotoxin characteristic for the organism has been demonstrated up to the present time (Sobernheim), although there is abundant clinical and anatomic evidence of intense intoxication. The production of mechanical injuries by the large masses of bacilli in the circulation is doubtful.

Prophylaxis.

Rational prophylaxis involves the proper disposal of the bodies of animals which have died of anthrax, the exclusion of animals from fields known to be infected, suitable disinfection of stalls, and finally protective inoculation against the disease. No part of the anthrax cadaver should be used for commercial purposes because of the danger of infecting those who work with the raw materials. Cleanliness and the usual precautions against contagious diseases should be observed by those who are exposed to infection, bearing in mind that the disease may be transmitted by way of the lungs and alimentary tract as well as by the skin.

Natural Immunity and Susceptibility.

It is probable that no disease is more perplexing from the standpoint of immunity than anthrax. The variations in susceptibility and immunity among different animals are extreme: Guinea-pigs, rabbits and mice are probably more susceptible than sheep and cattle; compared with these the dog and rat are relatively immune, whereas fowls and cold-blooded animals can be infected with difficulty. Although the microbe is readily killed by suitable serums (rabbit, e. g.), such an effect is not an index of immunity. The serum of the highly susceptible rabbit is strongly bactericidal in test-glass experiments, whereas that of the more resistant dog, or rat, has little or no bactericidal power. Because of this inconsistent relationship of the serum to immunity, and since the leucocytes have a high phagocytic power for the anthrax bacillus, Ptruschky, Frank and others, agree with Metchnikoff in assigning variations in the natural immunity of different animals to variations in phagocytic power. Bail and Pettersson, in extensive experimental work, discovered conditions which, they believe, explain the lack of correspondence between serum properties and natural immunity. In the serum of the relatively immune dog and chicken they found bactericidal amboceptors but no complement; hence the serum could show no bactericidal action in the test glass. If, however, leucocytes from the same animals were added to the serum, the latter became bactericidal. It may be assumed that in the course of infection the amboceptors are activated by complement which is discharged from the leucocytes. The failure of the bactericidal substances of the rabbit's serum to protect the animal was ascribed to the ability of the tissues to absorb the amboceptors (cited from Sobernheim). Their work is of sufficient importance to demand repetition.

Wright has shown the importance of the opsonins for phagocytosis of the anthrax bacillus.

Recovery from spontaneous infection is said to confer a certain degree of immunity of some duration.

Vaccination.

Artificial immunity may be produced by active or passive immunization. The first attempts at vaccination were made in 1880 by Toussaint, who injected the blood of infected animals after it had been heated to 55 degrees for ten minutes. The bacilli were thus attenuated, but they were able to form spores subsequently and vaccination was not always successful. Pasteur used two vaccines. Vaccine I consisted of a culture which was attenuated by a growth at 42 C., and which contained no spores. Vaccine II was a virulent culture, and was injected in from ten to fourteen days after vaccine I. Its use is said to have caused a decrease in anthrax in heavily infected districts, with a consequent decrease of the disease in man. Various modifications of the vaccines of Pasteur have been devised by others, and they seem to be equally successful. In some instances killed bacilli and the products of bacterial growth have been used with less success. The *Anthracase-Immunproteidin* of Emmerich and Löwe is not of established value.

Serum Therapy and Prophylaxis.

Immune serum for therapeutic purposes is prepared by immunization, first with killed or attenuated cultures and then with virulent strains. The two vaccines of Pasteur may be used. Although the serum has been shown to have fairly strong protective powers, it is of less value when used for curative purposes. It produces no effect after the blood stream has been invaded by the bacilli. Its greatest value is in the prophylactic injection of herds when anthrax has declared itself. In man it has been used chiefly in the treatment of malignant pustule in which the prognosis, even without specific treatment, is not unfavorable. The best known serums are those of Sclavo, prepared from the goat and ass, of Mendez and of Deutsch. The properties on which the value of the serums depends are unknown. Sobernheim is very positive in stating that the bactericidal power of an animal's serum is not increased by immunization or infection, and the existence of an antitoxin is not recognized. As in some other instances immunization may cause an increase in opsonins which would render the serum effective by its power to cause increased phagocytosis.

Mixed Immunization and Agglutination.

The method of Sobernheim, that of mixed active and passive immunization, seems to be successful as a prophylactic measure. The vaccine consists of a mixture of antiserum and bacilli. Immune and even normal serums at times may agglutinate the anthrax bacillus, but the reaction is inconstant, and the ability of an immune serum to cause agglutination is no index of its protective power. Agglutination is somewhat difficult of determination because of the tendency of the bacillus to grow in the form of chains.

RELAPSING FEVER.

The Parasite.

In 1868 Obermeier discovered in the blood of patients suffering from relapsing fever, "very fine threads exhibiting motility"; these "threads" have since been known as the *Spirochete obermeieri*,* and are recognized as the cause of the disease. They are very thin (about 1 micron), from 10 to 40 microns in length, and of spiral form. Three types of motion are described: a screw-like, a forward and backward movement and a lateral bending. They are found only in the blood and blood-forming organs. They disappear from the blood with remarkable rapidity at the time of crisis, although they may be found in the spleen one or two days later.

The spirillum has not been grown artificially, but it may be kept alive for a number of days in the blood or serum of patients. As the micro-organisms die agglomerations are formed and they undergo granular changes.

Transmission.

The organism is not found in Nature, and since it occurs only in the blood of the sick, it has long been assumed that infection can be accomplished only by the inoculation of infected blood. The parasites have been demonstrated repeatedly in bedbugs which are found on the mattresses of the sickbed and monkeys have been infected by inoculating them with the blood found in the bodies of these insects, and by the bites of the latter (Tictin). It is said that they may remain alive in bedbugs for as long as thirty days. It is not altogether excluded that other vermin also transmit the disease.

The spirillum does not appear in any of the excretions, unless they happen to be of a bloody character.

Certain monkeys, those belonging to the slender nosed family (*Catarrhinæ*), may be infected by injecting the blood of patients, provided the blood used is taken during the paroxysm, i. e., at a time when the microbes are known to be in the blood. Monkeys do not contract the disease under natural conditions. Other animals are not susceptible. The incubation period in man usually is from five to seven days, and in monkeys from one and one-half to four days. Cloudy swelling of the parenchymatous organs, ecchymoses and infarcts of the spleen and kidneys are found in fatal cases; these are not specific changes, however.

Prophylaxis consists in isolation of the patient, cleanliness, and the destruction of vermin, especially bedbugs.

Relapsing fever occurs in various races of man, and so far as known none are immune.[1] The natural immunity of other animals is referred either to phagocytosis or to normal bacteriolysins, but the conditions probably are not thoroughly understood.

As stated above, a remarkable feature in the course of the disease is the rapidity with which the micro-organisms disap-

---

* This organism is sometimes called a spirillum, incorrectly. The spirillaceæ, Migulas third family under the Order of Eubacteria, comprises organisms with these characteristics: "Cells which are twisted screw-fashion or represent a segment of a spiral. Division takes place only in one direction of space following elongation of the cell." The difference between spirillum and spirochæte is shown by the following: "3. Genus: Spirillum. Cells rigid, with polar tufts for the most part bent in the form of a half-circle as organs of locomotion. 4. Genus: Spirochæte. Cells with snake-like bending, organs of locomotion unknown."

[1] According to Osler the disease has not been seen in this country since 1869 when it was epidemic in New York and Philadelphia. This was before the discovery of the spirillum.

Phagocytosis and Bacteriolysins.

pear from the blood at the time of the paroxysm. Metchnikoff refers this to phagocytosis by the microphages, which undergo a progressive increase during the paroxysm and decrease after the crisis. Very little phagocytosis appears to take place in the circulating blood, but in the spleen many spirilla are found within polymorphonuclear leucocytes. Tictin also found them in the parenchymatous cells of the kidney, liver and lungs. Phagocytosis is most marked at or near the time of the crisis. According to Metchnikoff, the relapse or reinfection is accomplished by *spirilla* which again invade the body from the spleen.

Russian observers have studied the development of a specific bactericidal power in the serum of the sick and in animals which were immunized by the injection of infected blood from man. Inasmuch as the organism can not be cultivated, bactericidal tests must be performed with the organisms as they occur in the blood or serum of the patients, and Gabritschewsky has devised a technic for this procedure.

Technic.

A drop of serum from an immune animal or a convalescent patient is mixed on a slide with a drop of serum which contains the spirilla, the latter serum being taken from a patient during the paroxysm. The preparation is sealed under a coverglass and examined at intervals, and the death of the organisms is determined by their loss of motility. It is said that the bactericidal power of human blood following infection, and that of immunized animals, is increased.

Active and Passive Immunity.

In view of the facts that three or more relapses may occur and that reinfection is possible at a later period, it seems probable that man does not readily acquire immunity to the infection, although second and third relapses are said to be lighter than the first paroxysm. Monkeys which have been artificially infected several times acquire some resistance to the disease. The view of Metchnikoff that the spleen is essentially involved in recovery and immunity seems to have been disproved by the experiments of Tictin, who found that splenectomy had no influence on recovery or the development of immunity.

The serum of convalescents affords a certain degree of protection to the monkey (Gabritschewsky). Löventhal utilized the serum of immunized horses in the treatment of the disease in man, and reported a decrease in the number and severity of relapses. The action of the serum has been referred both to its content in bactericidal antibodies, and to its ability to stimulate phagocytosis.

Melkich states that agglutinins are formed and that they appear from the third to the fifth day of the disease.

A rapidly fatal disease of geese, spirochete septicemia, or spirillosis of geese, is caused by an organism which resembles the spirochete of Obermeier, and a similar infection has been noted in chickens in Brazil and in cattle in the Transvaal.

MALTA FEVER.

Malta, Mediterranean or undulant fever was discovered in the Island of Malta, is seen among British troops at Gibraltar, and cases have been discovered in the Carribean Sea, Porto Rico, in Hongkong and in Manila. It is said to be extending. The disease usually runs a long course, which is somewhat typhoidal in character, and there may be one or more relapses. The spleen is enlarged, but the intestines are not involved.

Bacillus melitensis, discovered by Bruce (1887) in the spleen of patients who had died of the disease, is a minute organism, slightly oval in shape and non-motile. It has not been found in the blood.

The bacillus is found in pure cultures in the spleen, which is greatly enlarged. Its growth in culture media is very slow.

It is thought that infected water may be one means of transmission of the disease. Laboratory infections have occurred through small wounds. The disease is not transmitted from person to person.

Up to the present time the monkey is the only animal known to be susceptible to artificial infection, although the organism may have a low degree of virulence for rabbits and guineapigs (Durham).

One attack confers immunity, which may disappear, however, after some time (Hughes).

Agglutinins, having a value of from 1-300 to 1-500, develop fairly early in the course of the infection and the agglutination test has been used successfuly in diagnosis.

An immune serum which was prepared by Wright is said to influence favorably the course of the disease.

Clinical Reports

QUININ AND IRON IN PNEUMONIA.

CHARLES F. NIEDER, M.D.

GENEVA, N. Y.

The results obtained by Dr. Galbraith,[1] of Sonora, Mex., in the treatment of pneumonia by the use of large doses of quinin sulphate and of the tincture of the chlorid of iron, as shown by the effect on the temperature, pulse and circulation, seemed to be of even greater importance than the fact that he had treated fifty consecutive cases without a death. Since reading Dr. Galbraith's last article I have treated six patients with lobar pneumonia in like manner, with very satisfactory results in every case.

Case 1.—J. H., aged 46, laborer, was taken ill March 8, 1905. He complained of severe headache and pain in the right side of the chest.

Examination.—Temperature, 102; pulse, 96; respiration, 28. Percussion of chest was negative. Breath sounds were suppressed on the right side. On March 9, at 10 a. m., temperature was 104.6; pulse, 120; respiration, 36. Percussion showed congestion of the lower lobe of the right lung. Pain in side was very severe. Expectoration was bloody.

Diagnosis.—Pneumonia.

Treatment.—Forty grains of quinin were administered, and two hours later fifteen grains were given, followed by ten drops of the tincture of the chlorid of iron every two hours.

March 10: At 9 a. m., temperature was 100; pulse, 94; respiration, 32. There was consolidation of the lower lobe of the right lung.

March 11: At 10 a. m., temperature was 101; pulse, 96; respiration, 34.

March 12: At 9 a. m., temperature was 101; pulse, 94; respiration, 35.

March 13: At 10 a. m., temperature was 104.5; pulse, 115; respiration, 54. There was consolidation of the whole of the right lung and of the lower lobe of the left lung. The patient was very drowsy. Forty grains of quinin were given at 12 m., thirty grains at 2 p. m., and thirty grains at 8 p. m.

March 15: At 8 a. m., temperature was 101; pulse, 92; respiration, 42.

March 16: At 9 a. m., temperature was 98.6; pulse, 88; respiration, 40.

March 17: At 10 a. m., temperature was 99; pulse, 82; respiration, 28.

Case 2.—D. Q., aged 38, moulder, was taken ill Sept. 6, 1905. He sat near an open window while perspiring freely on September 4. He had a very severe attack of pneumonia nine years ago.

Examination.—On September 6, at 8 a. m., temperature was 104; pulse, 125; respiration, 32. Percussion was negative. Breath sounds were suppressed over the lower lobe of the right side. The patient complained of severe pain in the right side.

Diagnosis.—Pneumonia, involving the lower lobe of the right lung.

Treatment.—Forty grains of quinin were administered at 8 a. m. and thirty grains at 4 p. m., followed by ten drops of the tincture of chlorid of iron every three hours.

September 7: At 9 a. m., temperature was 99.4; pulse, 86; respiration, 32. There was consolidation of the lower lobe of the right lung and severe pain in the right side.

September 8: At 9 a. m., temperature was 101.6; pulse, 92; respiration, 36. Twenty-five grains of quinin were given.

---

[1] The Journal, July 9, 1904, and Jan. 28, 1905.

September 9: At 9 a. m., temperature was 100; pulse, 78; respiration, 34.

September 10: At 10 a. m., temperature was 98.8; pulse, 75; respiration, 28.

September 11: At 10 a. m., temperature was 99.5; pulse, 76.

September 12: At 10 a. m., temperature was 98.4; pulse, 72.

Case 3.—A. P., aged 41, molder, had had a cold for one week. He was taken ill Sept. 12, 1905.

Examination.—On September 12, at 8 p. m., temperature was 104; pulse, 120; respiration, 35. His breathing was labored. There was no pain. Auscultation showed breath sounds suppressed over the lower lobe of the right lung, and percussion indicated congestion of the same area. The patient was very drowsy.

Diagnosis.—Pneumonia.

Treatment.—Thirty grains of quinin were administered at 8 p. m. and thirty-five grains at midnight, followed by ten drops of the tincture of chlorid of iron every three hours.

September 13: At 8 a. m., temperature was 99.8; pulse, 88; respiration, 32. There was severe pain in the right side, and the man was raising bloody sputum.

September 14: At 9 a. m., temperature was 100.4; pulse, 88; respiration, 34. There was consolidation of the lower lobe of the right lung.

September 15: At 9 a. m., temperature was 101.5; pulse, 90: respiration, 30.

September 16: At 10 a. m., temperature was 101.8; pulse, 90; respiration, 32. Twenty grains of quinin were given.

September 17: At 9 a. m., temperature was 100.6; pulse, 86.

September 18: At 9 a. m., temperature was 99; pulse, 78.

September 19: At 9 a. m., temperature was 100; pulse, 80.

September 20: At 9 a. m., temperature was 98.4; pulse, 74.

Remarks.—The results obtained in my other cases have been just as satisfactory as in these three cases.

With the exception of Case 1, at the time of the extension of the pneumonia to the other lung, none of the patients had a temperature exceeding 102 nor a pulse rate exceeding 96 after beginning this treatment.

What I wish to emphasize most is the effect of this treatment on the circulation. Instead of the high tension pulse which is usually present in pneumonia, the pulse was of nearly normal tension and of good volume. When there was cyanosis it was promptly relieved.

I trust that others will publish their results with Dr. Galbraith's treatment, so that we shall be able to arrive at a correct estimate of its value.

My experience is too limited to form satisfactory conclusions. Still, I am led to hope that the general use of this treatment will cause a great reduction in the mortality from pneumonia.

REPORT OF A CESAREAN SECTION.

JAMES W. ROWE, M.D.
Adjunct Professor of Obstetrics, University of Cincinnati.
CINCINNATI.

Previous History.—The patient was 26 years of age and weighed 96 pounds before the uterine contents were removed. She asserted that, when 2 years old, she was very sick with a fever, after recovering from which she did not walk for over a year. She was perfectly normal at birth and grew until 5 years old; since then she has grown broader, but very little taller.

Examination.—On examination the patient was found to be 41 inches in height. The head, face and neck were normal and the intelligence above the average. The trunk was small, but not especially deformed. From the spine of the seventh cervical vertebra to the tip of the coccyx measured 20½ inches. The extremities were markedly short, stumpy and deformed. The arm from the shoulder to the tip of the middle finger measured 14 inches. The legs were approximately 16 inches long.

Pelvis: The pelvic measurements were as follows: Between spines, 19.7 cm.; between crests, 21.8 cm.; between trochanters, 25.2 cm.; external conjugate, 14.7 cm. The true conjugate of the brim was estimated to be 6.5 cm.

History of Labor.—The patient last menstruated Nov. 23, 1904. On Sept. 11, 1905, labor began. I first saw the case on September 12 after she had been in labor twenty-four hours. At this time the os was as large as a quarter and the presenting part lay very high. Position and presentation were normal and the child was alive.

Operation.—The section was made following the usual technic. The uterine incision was made vertically through the anterior wall of the organ and, unfortunately, went through the placenta, so that it was necessary to work rapidly. After removal of its contents the uterus was closed with heavy catgut sutures one-third of an inch apart and extending through the entire thickness of the uterine wall, except the mucosa. Between these more superficial and finer sutures were placed to approximate the edges of the wound. A piece of gauze, the end of which extended through the os into the vagina, was left in the uterus. The abdominal wound was closed with three tiers of sutures. The gauze was removed *per vaginam* after twenty-four hours.

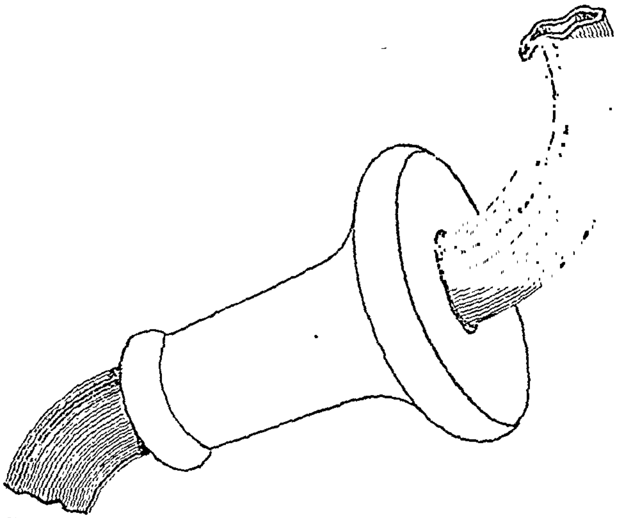
Result.—The patient recovered most uneventfully. Lactation began promptly and the baby flourished from the start. It weighed seven pounds and ten ounces. Mother and child were discharged after twenty-five days.

New Appliance

COMBINED MOUTH GAG AND STOMACH TUBE PROTECTER.

LAURENCE M. HYNSON, M.D.
WASHINGTON, D. C.

While resident physician at the Emergency Hospital in this city several months ago and having occasion to use the stomach tube in a great number of emergency cases brought into the hospital suffering from the effects of poisonous substances (taken for suicidal intent and otherwise), acute alcoholism, indigestion, etc., and finding in many of these cases the use of the mouth gag unsatisfactory, inasmuch as it was with the greatest difficulty that one could retain the gag in position with obstreperous patients, I was led to devise a simple instrument or bobbin which has proved to be very effective and which has the double feature of being mouth gag and stomach tube protecter combined. I made and used a mouthpiece of hard wood, as shown in the accompanying diagram, for the first time Sept. 6, 1904, and on subsequent occasions to great advantage.



It causes no laceration of lips, gums or tongue, and when once in position can not easily be removed by the movements of the patient's head or body. With one hand the operator holds both tube and mouthpiece in position, giving freedom of the other hand for the funnel end of the stomach tube. The gag has now been in use for several months at the Emergency Hospital of this city.

Those used so far have been made of hard wood, principally ash and hickory. The illustration is full size.

SATURDAY, NOVEMBER 18, 1905.

BIOGRAPHICAL CARD INDEX AND DIRECTORY.

Since the American Medical Association began the work of accumulating personal information from the members of the medical profession for the biographical card index and the American Medical Directory, many inquiries regarding these new lines of activity have been received. Physicians all over the country have asked, "*What is the biographical card index and what is its purpose? How will the American Medical Directory differ from other medical directories?*" The following is presented to answer these and other questions relating to the subject and to obviate the necessity of replying to each individual inquiry.

In order to understand the object of this work, it is necessary to examine carefully the present condition of the medical profession from a social and economic standpoint. The last century, and particularly the last twenty-five years, have witnessed a remarkable progress in medicine and in the allied sciences. This progress will unquestionably continue, and the army of observers and investigators now at work in every branch of medical science can safely be trusted with the technical side of a physician's work. But all thoughtful members of the profession admit that there are many practical questions relating to the training, the work and the life of the individual physician, as well as to the community in which he lives, that require careful study and consideration, as well as intelligent and conservative regulation. The improvement of the preliminary training of prospective medical students, of medical schools and of medical courses; higher standards for licensure by state authorities; reciprocity and mutual co-operation between state boards; protection of the ignorant and the sick from the quack, the faker and the charlatan; improvement of the social and financial conditions of the physician; stimulation of the desire to improve his own condition and to increase his knowledge and usefulness —all these much-needed lines of agitation and reform are blocked in the beginning by a lack of knowledge regarding the individual members of the medical profession.

As already stated, detailed information in all technical lines has increased a hundred-fold in the last half century. Along practical and sociologic lines, there is little more known than there was fifty years ago. No one knows how many individuals are at present engaged in the practice of medicine in the United States. Estimates vary from 110,000 to 140,000. Of this indefinite number, no one knows how many are properly licensed by the licensing body of the state in which they live. In many states, owing to the condition of the records, the state board itself can not tell whether a certain individual has *a right to practice medicine or not.* Information obtained by one state board at considerable expense and trouble is not utilized by others. Knowledge possessed by one society is not shared with other societies. Statements regarding college and year of graduation, as well as regarding state licensure, are in many cases most difficult of verification. If one desires data regarding a physician, there is no central bureau that can furnish it to him, no general clearing-house for information. Licensing bodies are continually met by the fact that they are unable to obtain reliable information whereby they may verify statements made by an applicant. There is not in existence to-day a list of the physicians of the United States whose legal qualifications to practice medicine have been verified. Out of the *fifty-four state and territorial licensing bodies,* only twenty-one have ever published a list of physicians legally qualified to practice medicine within their jurisdiction.

Information regarding members of the profession is difficult to obtain when desired for identifying, locating or tracing an individual physician for personal notices, biographical sketches, obituary notices, and all other purposes for which such information is desired. What has long been needed is an accurate compilation of data, made up of information obtained from official sources, such information then to be carefully edited and classified and kept corrected up to date, for the use and information of licensing bodies, and for any responsible person desiring information for legitimate purposes.

While the necessity for such classified information has been long recognized, until recently, conditions have not been favorable for its establishment and maintenance. Now with organization more or less completed, such is possible. In his annual report at the Portland session, the General Secretary of the American Medical Association said:

> It has long been recognized that a permanent biographical card index of American physicians, giving data in regard to preliminary education, medical education, previous locations, etc., would be of great value to the Association and to the profession. Such an index would be of value in tracing a physician through various localities, making up matter for directories and in compiling statistics in regard to the profession. This work has been begun and is now being carried on along two different lines, namely, first, the accumulation and indexing of biographical data in regard to the members of the profession now engaged in active practice; second, the accumulation of similar data in regard to graduates of the current year and of recent licentiates of state boards of health. This has been carried on through the assistance and co-operation of medical colleges and secretaries of state licensing boards. The amount of information on hand is considerable and is steadily increasing.

This was approved by the Committee on Reports of Officers and adopted by the House of Delegates, with instructions to the General Secretary to continue the work of collecting and classifying biographical information.

In accordance with this action, a biographical card index of the medical profession has been established, and it is hoped that very soon this index will contain a card for every physician in the United States. On the card will be recorded name, place and date of birth, preliminary education, medical college and year of graduation, state license and date, medical societies, college and life insurance positions, school of practice, and specialty, if any. In connection with this fundamental information, provisions are made for recording removals, positions held and other matters that may occur in the life of the individual that are of sufficient medical interest to note. Such information is pouring into the general offices of the Association from state and county societies, from licensing bodies, from newspaper clippings, the latter alone averaging over one hundred and fifty a day. Through the co-operation of medical colleges and state boards, certified lists of graduates and licentiates, together with most of the personal information requested, have been obtained and are now being properly classified. There is now in possession of the Association a fairly complete list of graduates of American medical colleges from 1860 to 1901. This list has been supplemented and brought up to date through the co-operation of registrars and secretaries of medical colleges. Copies of the official records of more than three-fourths of the licensing bodies have been secured. The remaining records are now being copied and will soon be completed. Blanks for reports both of colleges and of licensing boards have been prepared.

Each year a supplementary list of recently graduated and licensed physicians will be procured and added to the general index. There will thus be formed a list of all medical graduates, as well as of all legally qualified practitioners, made up from official records, and carefully corrected and revised each year. Information lacking regarding individuals will be constantly added. Thus it will be seen that the information asked for is primarily intended for this index. As a reliable and official list of legally qualified practitioners, it will be of great value and will undoubtedly aid in securing general reciprocity among licensing bodies.

The second reason for desiring this information is for use in compiling a reliable and accurate directory. The directory however, is only incidental to the other work. From the index will be drawn information, either personal or official, for compiling, revising and correcting the directory, both the one now in preparation, as well as subsequent editions.

The American Medical Directory will differ from directories heretofore issued in three particulars: First, it will be a directory of the American medical profession published and owned by physicians themselves. Second, information regarding college and year of graduation and date of licensure will be verified from official sources. Third, it will furnish the same information regarding each physician, whether he be a subscriber to the directory or not. No paid-for information will be included. It will also combine in one volume the purpose of a general medical directory, as well as a medical society blue book, since the names of all members in good standing of the constituent state associations and their component branches will appear in capital letters, as a distinctive mark of such membership. Information contained in the directory regarding each physician will include name in full, year of birth, college and year of graduation, office address and office hours.

The assistance and co-operation of all physicians, and especially all members of the organized profession, is earnestly requested in carrying on and developing this work. The greatest service that any physician can render at the present time is to furnish, promptly and accurately, information regarding himself. For the purpose of obtaining this information a blank has appeared in successive numbers of The Journal for the last six weeks. About 20,000 of these have been filled out and sent in.

A number of physicians have written saying: "You will find full information regarding me in the ——— Directory." As practically all directories are copyrighted works, it will be readily seen that such information is not available for the purposes desired. Other physicians have replied, saying, "You will find my complete record in the Transactions of the ——— Medical Society for the year ——." A moment's reflection will show the difficulty in tracing up the personal record in this way. The time required for a physician to fill out and return these blanks is infinitesimal; the time required for the directory office force to trace each individual is great. If each reader of The Journal will furnish at once, without further solicitation, the personal information regarding himself, the work of accumulating the data will be greatly simplified. On advertising page 32 of this issue will be found the information blank desired. All readers of The Journal who have not already done so, are urged to furnish this information at once.

THE VALUE OF SINGLE CLINICAL SYMPTOMS IN THE DIAGNOSIS OF TYPHOID FEVER.

In no common disease more than in typhoid fever does the diagnosis depend on the correlation of single symptoms, and no common disease is more often incorrectly diagnosed. If the Spanish War had shown nothing else of medical interest, the information it gave us regarding the difficulty of diagnosing this disease would have been of inestimable value. Those who looked over the admirable report of Reed, Shakespeare and Vaughan must have been struck with the fact that more mistakes in diagnosis were made in connection with typhoid than with any other common condition. In civil practice, too, a similar condition has prevailed and still prevails. Too many practitioners still fail to realize that a fever that does not yield with reasonable promptness to quinin is not malaria, and that in many districts the only continued fever is typhoid. It is but a few years since Osler, in an address before a New York audience, called attention to the frequency with which malaria was given as a cause of death in that state, and with gentle and good-natured sarcasm referred to typhoid fever as "New York malaria." On the other hand, in many cases typhoid is made the scapegoat, and any obscure condition is diagnosed as typhoid fever.

Superstition, though dormant or appearing in aberrant forms, still enters into the constituent parts of humanity. In medicine, as elsewhere, superstitions die hard, and the superstition of the pathognomonic sign dies hardest of all. Who has not met the practitioner who, in diagnosing a fever case, says: "No, this can not be a typhoid-fever case, for the patient has not a typhoid tongue." If it is not the tongue it is the pea-soup discharges or delirium or a typical fever. If we are to rely on single symptoms and signs, or on groups of prominent symptoms and signs, what are the important ones in this disease? Are the more modern methods, when available, of striking value? These questions have been considered and answered in a recent paper of Treupel.[1] This author's analysis of his carefully studied cases shows that some of the signs and symptoms supposed to be most characteristic appear in a remarkably small percentage of cases, and they also indicate the great value of certain of the more recent methods of diagnosis.

There are certain facts of essential importance which should always be considered in reaching a conclusion as to whether a given patient has or has not typhoid fever. The history of the prodromal symptoms, either general or referred to special organs, the temperature, the pulse, and especially its relation to the degree of fever, the involvement of the respiratory organs, the condition of the tongue and of the digestive tract in general, the presence or absence of an enlarged spleen, the skin eruption, the Widal reaction and the presence or absence of typhoid bacilli from the blood. The two last-mentioned signs are relatively new, and while the Widal reaction is now generally used, blood cultures have not yet come into general favor. Treupel's analysis deals with all of these factors, and gives the relative value of each in figures. The results are interesting. The typhoid tongue, for instance, was present in only 16 per cent. of his cases, and a typical temperature curve in less than 50 per cent. Pea-soup stools were the exception and constipation the rule. Bronchitis occurred in less than 50 per cent. of the cases. Far outclassing every other sign as regards frequency of occurrence were the two new diagnostic measures, the Widal reaction (90.6 per cent.), and the presence of typhoid bacilli in the blood (92.8 per cent.). Of the signs which are appreciable to the senses, and do not need the aid of laboratory methods to bring them out, the most important are the enlarged spleen, the relatively low pulse rate, the rose spots and abdominal tenderness or meteorism.

One is tempted to ask whether the signs and symptoms of a given disease may not vary from generation to generation; whether we do not expect to find certain symptoms and signs because professional tradition has taught us to expect them. There is no doubt as to the clinical acuity of our professional forbears; so far as the unaided senses are concerned, in all likelihood they were much better observers than we are. There are good reasons on theoretical grounds why infectious diseases should become modified in the course of time, and not a little practical proof that this has actually occurred in some cases. In all probability it has taken place to some extent in typhoid fever, partly, no doubt, as the result of changes in treatment. Even the text-books suggest it. It is to be hoped that the fact will soon be more widely appreciated.

FEDERAL PROTECTION OF THE PUBLIC HEALTH.

One of the most important and most significant of the favorable results of the late epidemic of yellow fever has been the widespread agitation in the southern states, having as its object the creation of a public sentiment in favor of transferring to the Federal Government all matters of national and interstate quarantine. This is all the more notable because heretofore it has been chiefly the southern adhesion to a strict construction of the rights of the state that has prevented the development of a national department of health. In order to show the character of this change in sentiment, we reproduce in this issue[1] a few excerpts from southern press editorials, together with expressions from prominent state governors. Those interested in public health development will find these very significant.

Clearly, the present is the opportune time for asking Congress to create a department of health, to which shall be assigned certain duties in national and interstate quarantine, together with various incidental tasks, such as collecting general and accurate vital statistics. It would not seem to require any stretching of federal function to assign to this new department the sanitary policing of all the navigable waters of the nation, which, by the United States Constitution, are declared to be a part of the national domain, and are placed under the authority of Congress. By a persistent national application of this new function, it is reasonable to think that much improvement would be noted in the mortality from diseases whose infection is waterborne. To this new department would logically fall the execution of the provisions of the pure food and drug law, which will sooner or later be placed on the statute books. Other and important functions will suggest themselves, such as the problems of immigration, and of sanitation in Panama, Porto Rico, Alaska and the Philippines. In such a department all the medical activities of the government could be centralized and harmonized.

It is unfortunate that up to the present time no proposed law for the establishment of a national department of health has been satisfactory to all students of the subject. Certainly, however, this does not imply that a comprehensive and safe measure can not be drawn. Beyond doubt there never has been a time in the history of the country when the conditions were so favorable for the friendly and interested consideration of such a measure by Congress.

---

[1] Muench. med. Wochft., 1905, vol. lii, p. 1870.

[1] See page 1593.

In addition to others mentioned as willing to permit enlargement of the functions of the General Government in the direction of public health duties, it must be borne in mind as highly significant that Governor Cox of Tennessee felt so much interest in the movement that he called a conference of governors, health officials and other citizens of the southern states at Chattanooga, November 9 to 11. At this conference Congressman John Sharp Williams, Democratic leader in the United States House of Representatives, was made chairman of the committee on quarantine, and this committee brought in a report recommending federal control of foreign and maritime quarantines and control of interstate quarantine by the individual states in co-operation with the Federal Government. This report having been adopted, the question is certainly before the country in active form.

THE POWER AND INFLUENCE OF THE PROPRIETARY ASSOCIATION OF AMERICA.

During the last two or three weeks the newspapers of the country have been publishing from paragraphs to columns of matter denouncing the "unjust attacks on a legitimate (?) business" and abusing *Collier's Weekly* for publishing "sensational articles which are calculated to mislead the public." We have never known before what a noble, self-sacrificing business that of the nostrum manufacturer is, nor have we realized how necessary to human life these nostrums are. Sophistry, half-truths and plausible arguments are so intermixed that, to the ordinary individual, it would seem that the nostrum business is not only legitimate and honorable, but absolutely necessary for the welfare of the race. Except in rare instances this matter has not appeared in the metropolitan and leading dailies, for evident reasons, but the smaller newspapers and those that are less independent seem to be the ones that are compelled to defend the "Great American Fraud." The country newspapers which use the "patent-insides" are relieved of any responsibility, for the "defense" is in that part of the paper which they buy already printed.

While these articles have appeared in the public press in all parts of the country practically simultaneously, there is such a sameness about the style, the arguments used are so similar, and in general character so uniform, that one at once concludes that they must have a common origin. This conclusion would be reached even if there were no other evidence; but the letter we reproduced last week in a comment on "A Newspaper Free from Nostrum Ads.," written by the chairman of the press committee of the Proprietary Association, clearly proves the source. By the way, the "communication" which was sent to the newspapers with the letter referred to was the one from Mr. Bok, which appeared in THE JOURNAL of the American Medical Association,[1] in which he urged physicians to take up the fight against patent medicines. The object of the press committee of the American Proprietary Association evidently was to convey the idea that physicians are instigating the propaganda against "patent" medicine, and the dear people are being told that this is a fact and that the doctors oppose "patent" medicines for selfish reasons. Incidentally, the medical profession, the American Medical Association and THE JOURNAL of the American Medical Association are sadly abused.

What is this organization that has such a power over the newspapers of the country that it can compel them to speak or to be silent? Does this power lie in its numerical strength, in its wealth, or in the social influence of its members? To enlighten our readers, and, indirectly, the public, we print in this issue[2] a complete list of the members of this Proprietary Association of America, taken from their own transactions recently issued.

A glance at this list will give one an idea of the enormous wealth represented, so enormous that it is no exaggeration to say that it is one of the most powerful organizations in the country, from a financial point of view, and that it is not hard to believe that its members pay to the press of the country at least forty million dollars annually, as stated by one of them. Those who are interested in the nostrum question—whether as it relates to the so-called "patent" medicines advertised directly to the public or to those which are exploited to physicians—will find it worth while to give this list a careful study. In the first place, it will be found that there are a few firms in the list which are engaged in an honorable and commendable business. There may be a dozen of these, all told.

Further, it may be noted that scattered through the list are names that are familiar to readers of the advertising pages of medical journals—another evidence of the inseparableness of "patents" and "proprietaries." Another very important fact would be evident if we had space to give the personnel of the firms; a large number of those who under one company are "patent medicine men," under another are, in a very dignified way, exploiting "proprietary" medicines to physicians.

These various firms have banded together, for what? To protect the interests of what Samuel Hopkins Adams calls "The Great American Fraud"; to protect the interests of a business that is both infamous and despicable; a business in which few men will, without blushing, acknowledge that they are engaged; a business that thrives on misrepresentation and fraud, that fattens on the gullibility and credulity of the ignorant, and that prospers by deceiving the sick and afflicted.

---

[1] THE JOURNAL A. M. A., May 20, 1905, p. 1628.

[2] See page 1589.

This language may seem harsh. We acknowledge that it is. But is it too harsh when all the facts are known regarding the business and the methods of at least a large majority of the firms which are listed as members of the Proprietary Association of America?

LIQUOZONE.

Collier's for the current week contains Samuel Hopkins Adams' contribution on that wonderful preparation, "Liquozone," a nostrum that has been more widely exploited, and with more extravagant claims, in the short time that it has been before the public, than any other patent medicine, so far as we are aware. The methods adopted by its promoters have been so effective that the backers and endorsers of the preparation evidently thought they had struck a gold mine, figuratively speaking. It is a pity that Mr. Adams did not "name names" when he was speaking of the promoters and stockholders who "are prominent socially and forward in civic activities," for then it would have struck at the root of the matter as far as this particular company is concerned. One of the directors, we have been informed, has recently been elected to a high office in one of the leading social clubs of Chicago, and another prominent figure in the company is a leader in a movement for bettering the political conditions in Chicago. We understand, however, that there is more to come in regard to liquozone than is to appear in *Collier's Weekly*, and the probability is that the whole concern will be so shown up that those connected with it will wish that they had never lent themselves or their "influence" to such a business.

THE RETIREMENT OF DR. BIDDLE.

The announcement is made in the last number of the *Journal of the Michigan State Medical Society*, of the resignation of Dr. A. P. Biddle, secretary of that society, and editor of the journal. Dr. Biddle resigns owing to increased demands of work along other lines. The Michigan State Medical Society has accepted the resignation to take effect January 1, and voices its regret at Dr. Biddle's resignation, as well as its appreciation for his faithful and energetic services. This sentiment will be echoed by all officers and members of the American Medical Association who have come in contact with Dr. Biddle during the years of his secretaryship. He has always performed the arduous duties of his position cheerfully, promptly and effectively during the time that he has occupied the secretary's office. He has seen the state medical society grow to its present proportions and the *Journal of the Michigan State Medical Society* develop into one of the best state journals in the country. It is to be hoped that Dr. Biddle's retirement from the secretaryship will not mean that he will cease to take an interest in medical organization or to work as earnestly as heretofore, for the good of his state association and of the American Medical Association.

Active Congestion of Lungs.—Aconite is especially indicated in inflammatory states of the respiratory organs—one-half to one drop every half-hour until an impression is made on the fever movement, then every hour or two.—Bartholow.

Medical News

CALIFORNIA.

Sanitarium Opened.—The Loma Linda Sanitarium, near Redlands, a well-equipped branch of the Battle Creek Sanitarium, was opened to the public October 1.

Hospital Opened.—The new hospital of the Santa Fe System, Los Angeles, a three-story building in mission style, erected at a cost of $80,000, was formally opened November 1.

October in the Hospitals.—During October, 1,747 patients were treated at the five emergency hospitals in San Francisco. In the previous month 1,643 cases were treated, while in October, 1904, there were but 1,300 patients.

Hospital Association Meeting.—At the annual meeting of the Santa Ana Hospital Association, Drs. Charles D. Ball, Frances M. Bruner, John L. Dryer, Howard S. Gordon, James R. Medlock, Willela Howe-Waffle and John Wehrly were elected directors, and the directors thereon organized by electing Dr. Dryer, president; Dr. Bruner, vice-president; Dr. Ball, secretary, and Dr. Gordon, treasurer.

Personal.—Dr. Eleanora S. Yelland, Los Gatos, is visiting in Connecticut.——Dr. Carl R. Krone, Oakland, has resigned as superintendent of the East Bay Sanatorium and will resume private practice.——Dr. Ellis Harbert, Stockton, has been appointed division surgeon for the Santa Fe System.——Dr. Harry McNulty, San Francisco, formerly surgeon of the steamship *Sonoma*, has entirely recovered from his recent serious operation.

Crusade Against Patent Medicines.—The Board of Health of Los Angeles is reported to have begun a crusade against patent medicines which contain either poisons or alcohol. An analysis of all the more prominent patent medicines is being made, and the report will be published. There is a California law which has never been enforced which requires sellers of proprietary medicines to label the preparation with the name of any poison it may contain. Failure so to label the bottles is made a misdemeanor and a severe penalty is provided. Dealers in nostrums will be given a reasonable time in which to comply with the requirements of the law in this respect. and failure to do so will be followed by criminal prosecution. It is said that the board of health has secured from the city attorney's office the announcement that there is ample authority under the law for this crusade.

IDAHO.

New Regimental Surgeon.—Governor Gooding has commissioned Lieutenant-Governor Burpee L. Steves, Weiser, as major surgeon of the Second Infantry, Idaho National Guard, vice Major Castle, resigned.

New Hospital Opened.—The new hospital at Idaho Soldiers' Home, Boise, erected at a cost of $10,000, was formally accepted and occupied November 2. The 7 patients in the old building were removed to their new quarters.

Personal.—Dr. Robert L. Nourse, Hailey, is about to move to Boise, but before doing so he will go to Europe to take postgraduate work in the treatment of the eye, ear, nose and throat.——Dr. and Mrs. G. C. Kilgour, Roosevelt, have gone to Chicago.

ILLINOIS.

Cornerstone Laid.—The cornerstone of the new St. Vincent's Hospital, Taylorville, was laid November 8 with impressive ceremony.

Silver Wedding.—Dr. and Mrs. J. Leaming Wiggins, East St. Louis, celebrated the twenty-fifth anniversary of their marriage October 22.

Hospital Changes.—Drs. J. C. and J. E. Weld, Milford, have been appointed to the staff of the Illinois Eastern Hospital for the Insane.

Hospital at Mattoon.—The trustees of the Memorial Methodist Hospital Association of Mattoon have recently purchased a 25-room residence and will so remodel it that it will accommodate about 20 patients.

Pure Food Crusade.—It is reported that the Illinois Consumers' League is to co-operate with the General Federation of Women's Clubs in the crusade for pure food. A committee has been appointed to call the attention of the women of the state to the adulteration of foodstuffs.

Hospital Staff Elected.—The medical staff of Blessing Hospital, Quincy, met October 30 and elected Dr. Kirk Shawgo physician-in-charge; Dr. William S. Knapheide, surgeon-in-charge; Dr. John H. Rice, gynecologist-in-charge; Dr. Melinda C. K. Germann, obstetrician; Dr. Clarence A. Wells, anesthetist; Dr. Frederic M. Pendleton, oculist and aurist, and Dr. George E. Rosenthal, pathologist.

Southern Medical Association.—The Southern Illinois Medical Association met in Mount Vernon November 1 and 2 and elected the following officers: President, Dr. J. Leaming Wiggins, East St. Louis; vice-presidents, Drs. Charles C. Grizzell, De Soto, and James W. Hamilton, Mount Vernon; secretary, Dr. Edgar E. Fyke, Centralia; associate secretary, Dr. Charles W. Lillie, East St. Louis, and treasurer, Dr. Alexis T. Telford, Olney. The next meeting will be held in Shawneetown.

Chicago.

Personal.—Dr. Samuel J. Walker has been seriously ill from septic infection due to a postmortem wound.

Senn Club.—The Nicholas Senn Club has been incorporated in Chicago for scientific research by Drs. Byron Robinson, Orville W. Mackellar and Arthur McNeal.

Hospital Borrows Money.—The Sisters of the Holy Family of Nazareth have obtained a loan of $50,000 for ten years, secured on the site of the Hospital of St. Mary of Nazareth and subject to a prior incumbrance of $150,000.

Refuses to Stop Examinations.—Master in Chancery Mason on November 6 denied the motion for an injunction to restrain the civil service commission of Cook County from continuing the examination for positions on the staff of the County Hospital.

Diphtheria.—During the week ended November 11, 17 fewer cases of diphtheria were reported than during the previous week, and although there was an increase of more than 31 per cent. in the number of requests for bacterial examinations of suspected cases of the disease, there was a decrease of more than 27 per cent. in the positive findings.

Deaths of the Week.—The total deaths for the week ended November 11 were 469, 29 less than for the preceding week and 56 more than for the corresponding week of 1904. The respective annual death rates per 1,000 were 12.28, 13.04 and 11.17. The chief causes of death were: Pneumonia, 63; consumption, 49; nephritis, 45; heart diseases, 40; violence, including suicide, 35, and cancer and acute intestinal diseases, each 28.

Alkaloidal Clinic Burned Out.—The three-story brick building occupied in part by the *Alkaloidal Clinic*, at Ravenswood, with the presses and publishing equipment, was completely destroyed by fire November 2, at a loss of $200,000. The large wooden building, closely adjoining, containing the offices and stock of the Abbott Alkaloidal Company, was saved. Dr. Abbott and his associates have at once taken up plans for a new start, proposing to issue a clinical journal of a broader scope than formerly.

INDIANA.

Gift to Hospital.—James M. Laboyteaux, a farmer living near Muncie, has contributed $1,000 toward the erection of a county hospital and, if necessary, will duplicate the gift.

New Medical Building.—Ground has been broken for a new building for the medical department of Valparaiso University, to cost about $50,000. The first winter term opened November 14.

In Guardian's Charge.—Dr. John Williams, Bowling Green, 96 years of age, who has practiced medicine for nearly seventy years in the state, was placed under the charge of a guardian November 6.

Schools Reopened.—The city schools and public library of Columbia City, which have been closed on account of a diphtheria epidemic, will reopen November 6.——The Potomac schools, which have been closed for a week on account of scarlet fever, were reopened November 4.

Magazines Consolidated.—The *Central States Medical Magazine*, Anderson, and the *Medical and Surgical Monitor*, Indianapolis, have been merged as the *Central States Medical Monitor*, to be published in Indianapolis. Dr. Samuel E. Earp will be the editor, and Dr. Samuel C. Norris will edit the eye, ear, nose and throat department.

Personal.—Dr. M. Hassenmiller, West Baden, has gone to Europe. Dr. Chauncey W. Dowden, Bloomington, has taken his place as house physician at the West Baden Springs Hotel.——Dr. Charles R. Dancer, house physician at the Indiana School for Feeble-minded Youth, Fort Wayne, has resigned, to take effect November 1. Dr. Budd Van Sweringen has taken charge of the work at the institution until a successor is appointed.——Dr. John W. McGowan, Oakland City, who has been seriously ill with septicemia, is now believed to be convalescing.——Dr. Peter J. Pothuisje, Remington, has gone to Colorado.——Dr. Charles T. Bronaugh, Crawfordsville, who has been visiting in California, has returned.——Dr. Brose S. Horne, Marion, has moved to the Indian Territory.

IOWA.

Semi-Centennial.—The Fremont County Medical Society held a meeting November 1, at which a banquet was given in honor of Dr. Thomas G. Stephens, Sidney, who has just entered on his fiftieth year of medical practice.

Northwestern Physicians Meet.—At a meeting of the Northwestern Iowa Medical Association in Carroll October 26, Dr. Patrick J. Barry, Auburn, was elected president; Dr. A. L. Brooks, Audubon, vice-president; Dr. Giles C. Moorehead, Ida Grove, secretary, and Dr. Daniel J. Townsend, Lohrville, treasurer. In the evening a banquet was tendered the members of the association and the invited guests by Dr. Arthur L. Wright.

Diphtheria.—A number of country schools in Polk County are closed on account of the prevalence of diphtheria.——The schools of Anken and Elm Grove have been closed in an endeavor to check the spread of diphtheria, which has been prevalent in these towns.——There are several cases of diphtheria in Cedar Rapids.——As many as 30 cases have been reported to the city physician of Des Moines in one day.——Dubuque has diphtheria in almost epidemic form.

Personal.—The State Board of Health has elected Dr. Henry Albert director of the State Board of Health Bacteriologic Laboratory, Iowa City.——Dr. Robert D. Wilkins, Atlantic, was thrown violently against a seat on a train en route to Chicago October 16, breaking three ribs.——Dr. Alanson M. Pond, Webster City, has gone to Europe.——Dr. Nathaniel La K. Slamberg, Kimballton, has been appointed surgeon at the Pine Ridge Indian Agency, South Dakota.——Dr. Herbert M. Decker, Davenport, has been appointed assistant state bacteriologist.

In the Courts.—Mrs. Stiles, Atlantic, arrested for peddling medicines without license, plead guilty, paid the costs of the case, amounting to $14.05, and took out the regular $100 license.——Dr. Charles McKinnis, Ollie, charged with issuing prescriptions for liquor, has been placed under bonds of $1,000.——Dr. James C. Smith, Woolstock, has been permanently enjoined from selling intoxicating liquor of any kind in violation of law in the town of Woolstock or in any other place within the eleventh judicial district. The costs and attorney's fees were taxed to the defendant.——"Dr." J. R. Baker, Odebolt, who plead guilty to using the mails to defraud by the sale of a medicine, has been sentenced to six months' imprisonment in the state penitentiary at Anamosa.——Dr. Palmer, Fort Dodge, has been adjudged an habitual user of drugs by Judge Richard and committed to the Cherokee State Hospital for two years.——In the malpractice suit brought against Dr. Pattison of Oelwein by Mrs. Ackerson, in which $10,000 damages were asked, the jury rendered a verdict of $100 for the plaintiff.

KENTUCKY.

Medicine Vendor Fined.—A patent medicine vendor was fined $50 at Georgetown for selling medicines without a state license.

Personal.—Drs. Palmer G. Keeney, Edward S. Wendt and Oscar A. Frickman have been elected district physicians for Newport.

Physician Stabbed.—Dr. Robert A. Irwine, Clay City, a well-known physician of Powell County, was stabbed several times by an ex-convict November 4 and is in a serious condition.

Diphtheria is prevalent in Hancock and the eastern part of Daviess County, and the schools at Panther Creek, Floral and several other places have been closed on account of the disease.

New Hospital Started.—Ground was broken November 5 for the foundation of the new Good Samaritan Hospital, Louisville, to be built by public subscription. Of the fund of $50,000 required to complete the building on the plans proposed, $26,500 is already in hand.

MISSISSIPPI.

Personal.—Dr. J. Hewlett, Meridian, quarantine inspector, has resigned.——Dr. William Neville has been appointed health officer of Macomb City.——Dr. Troy C. Sexton, Laurel, is reported to be critically ill.

Marine-Hospital Records Burn.—At a fire at Jackson October 2, the records of the United States Public Health and [illegible] Passed Assistant Surgeon [illegible] Surgeon Young [illegible]

[illegible] board of trustees of the [illegible] Jackson, has decided to ask [illegible] of $150,000 for the pur- [illegible] and making necessary improve- [illegible] now crowded to overflowing and the [illegible] a detached building erected for a hospi- [illegible] treatment of tuberculous patients.

To Examine into Insane Hospital Management.—Governor Vardaman has appointed a commission to examine into the management of the state insane hospitals located at Jackson and Meridian, consisting of Drs. Vardaman S. McLellan, Canton; Donald P. Street, Vicksburg; Ernest Spiva, Sturgis; Jefferson D. Smythe, Greenville; James W. Gray, Jr, Clarksdale; C. H. Ramsey, Collins, and John W. Young, Grenada.

MISSOURI.

Personal.—Dr. August Rhodes, Carthage, is critically ill at his home in that city.

Smallpox Epidemic.—Birchtree and the adjacent portion of *Shannon County* are suffering severely from a smallpox epidemic. There are reported to be at least 10 cases, and 4 deaths have occurred.

Opposes Club Doctors.—The Jackson County Medical Society adopted a resolution calling on all physicians engaged by lodges, societies and commercial institutions under contract prices, to resign at once under penalty of suspension from the society.

Diphtheria.—During the month of October 47 cases of diphtheria were reported in Kansas City, 14 less than on the corresponding day of 1904.——The board of health has ordered the fumigation of the Horace Mann and Linwood schools, in which districts the disease has been most prevalent.

Patent Medicine Advertisements.—The secretary of the St. Louis Medical Society has written to the city attorney of St. Louis, calling attention to a violation of city ordinances in the advertising of patent medicines. Some advertisements were characterized as obscene. The latter stated that the legislative committee of the society had appointed a committee consisting of Drs. George Homan, John Young Brown and Henry J. Scherck, to co-operate with the city attorney in enforcing a strict observation of the ordinances regarding advertising.

NEW MEXICO.

Hospital Society Organized.—The citizens of Albuquerque, claiming that eastern and western physicians are in the habit of sending dying tuberculous patients to that city, have established an associated charity hospital for those at present in the city, and will engage in a determined effort to put a stop to the practice of sending the hopelessly ill to New Mexico in the future.

Sanatorium to Open.—The New Mexico Cottage Sanatorium, Silver City, is nearly completed and will be open for patients November 25. The institution will be under the personal management of Dr. Earl S. Bullock. It consists of two main buildings and fifteen separate cottages, each of which accommodates one patient. The institution will be devoted exclusively to the care and treatment of cases of laryngeal and pulmonary tuberculosis.

NEW YORK.

board of Thrall Hospital, at Middletown. The resignation of Dr. Edwin Fancher of the attending board was accepted and he was elected a member of the consulting board.

Northern New York Physicians.—The Medical Association of Northern New York met in Malone October 24 and elected the following officers: President, Dr. E. S. McClellan, Saranac Lake; vice-president, Dr. William C. Smith, Winthrop; secretary, Dr. Alfred G. Wilding, Malone, and treasurer, Dr. George H. Oliver, Malone. The association will meet in Malone next year.

Visitors to State Hospital.—The State Hospital, Buffalo, was visited October 23 by a royal commission of English visitors and philanthropists, who are making a tour of investigation of the institutions for the care and control of the feeble-minded in the United States. The commission was made up of W. B. Byrne, C.B., W. H. Dickinson, H. B. Donkin, F.R.C.P., J. D. Dunlop, F.R.C.P., and Mrs. Hume Pinsent.

Diphtheria.—Diphtheria is reported epidemic in Charlotte, and strict quarantine is being observed.——Public schools 59, 60, 64 and 65 of Brooklyn have been ordered closed pending official investigation of diphtheria which is prevalent in that section.——The public schools of Union Course have been ordered closed by the health department because the residents of that section would not allow the health inspectors to examine their children.

Central New York Physicians.—The Medical Association of Central New York held its thirty-eighth annual meeting in Buffalo October 24. Among the papers read was one on bony atrophy by Dr. Louis A. Weigel, Rochester, who as the result of his researches into the employment of *x*-rays, recently lost his right arm and three fingers of his left hand. The following officers were elected: President, Dr. David M. Totman, Syracuse; vice-presidents, Drs. William B. Jones, Rochester, and Lemuel L. Tozier, Batavia; secretary, Dr. Clarence A. Greenleaf, Rochester, and treasurer, Dr. William M. Brown, Rochester.

Personal.—Dr. Robert Frazer of the staff of the Riverside Accident Hospital, Buffalo, was operated on October 17 for appendicitis, and is reported as improving.——Dr. Max C. Breuer and family, Buffalo, returned from Europe October 21.——Dr. Fred M. Barney, Dolgeville, has received a government appointment in Cuba.——Dr. James E. O'Malley, Newburgh, who has been confined to his home for some time as the result of a broken patella, has resumed practice.——Dr. George H. Torney, first assistant physician at the State Hospital, Utica, has gone to California for a visit.——Dr. Douglas A. White, superintendent of the Hospital of the Good Shepherd, Syracuse, has resigned, to take effect December 1.——Bert E. Nelson has been appointed bacteriologist of the board of health of Binghamton.——Dr. Warren B. Stone has been appointed bacteriologist of Schenectady, vice Dr. Norman B. Saunders, removed from the city.——Dr. Henry H. Davidson, Northport, formerly coroner of Suffolk County, fell October 24 while walking across his office and fractured his hip.

New York City.

Home for Consumptives.—Under the direction of the *Tribune* Sunshine Society, Dr. James S. Ennis is to establish a Home for Consumptives in Florida.

New York Surgical Society.—At the annual meeting of this society November 8 the following officers were elected: President, Dr. George Woolsey; vice-president, Dr. Joseph A. Blake, and secretary and treasurer, Dr. John A. Hartwell.

Personal.—Dr. William J. Robinson, editor of the *Medico-Pharmaceutical Critic and Guide*, has returned from Europe after an absence of nine months.——Drs. Murray M. Rarick and W. E. Lippold have been appointed house surgeons and Dr. E. J. Dorn, ambulance surgeon, at the Williamsburg Hospital.

Signed False Death Certificate.—Dr. George E. Morgan, who in July last gave a certificate of the death of Mamie Jeanette Thompson, certifying that she had died from tumor, pleaded guilty November 8 to having falsely signed a death certificate and was sentenced to ten days' imprisonment in the Tombs and to a fine of $200.

Contagious Diseases.—There were reported to the sanitary [illegible]eau for the week ended November 4, 363 cases of tuber[illegible], with 150 deaths; 279 cases of diphtheria, with 22 [illegible] 169 cases of measles, with 5 deaths; 77 cases of ty[illegible]ver, with 11 deaths; 79 cases of scarlet fever, with 6 [illegible] 9 cases of cerebrospinal meningitis, with 15 deaths, [illegible]ses of chickenpox.

Benefit.—A bazaar given at the Waldorf-Astoria [illegible] 8 netted $6,000 for the Hospital for Crippled

Children.——The late Miss Margarette A. Jones has left the Postgraduate, St. Luke's and the Presbyterian hospitals a bequest which will give to each institution more than $200,000, the income of which is to be devoted to the care of poor patients.——The late John Inglis has left the Presbyterian Hospital $1,000.——By the will of Rebecca M. St. John the Northern Dispensary of New York will receive $3,000.

Hospital News.—The new wing of St. Vincent's Hospital, Manhattan, was formally opened November 1. The new building is seven stories high and has accommodation for 100 patients. It is fireproof and is thoroughly equipped.——Certificate of incorporation has been filed with the secretary of state by St. Joseph's Hospital, Far Rockaway, for the maintenance of a general hospital.——Bensonhurst Sanatorium Company has been incorporated in Brooklyn, with a capital stock of $100,000, by Dr. Earl H. Mayne and others.——The new Washington Heights Hospital was formally dedicated October 15.

Home Cure of Consumption.—The College of Physicians and Surgeons, Columbia University, announces favorable results of a plan for the cure of tuberculosis which has been employed in an experimental way for the past two years. This plan consists in treating the patient at the clinic and his home. Advice is given both verbally and on printed slips, instructing him how to live a sanitary life, and medicine is furnished when necessary. Each patient is placed in the care of a visiting nurse, who reports to the physician the conditions found at the home. During the two years in which the plan has been in operation there have usually been about 100 cases under treatment at one time. During the past year 408 patients were treated and 2,746 visits were made by the nurse.

Hospitals Wasteful.—The report of the findings of the committee on hospital needs and hospital finances, which has been at work since March of this year, states that the private hospitals of New York are extravagant in the use of costly drugs and dressings and that they do not receive the support from charitable persons that their work deserves. This committee is composed of men of large hospital experience and responsibility, who suggest that there should be uniformity in keeping accounts and making reports of work done, as the public has a right to know that hospitals are run under the most economical basis consistent with efficiency in treatment. The committee also suggests that the hospitals co-operate and purchase coal "in cargo" and that by similar co-operation they might be able to compel the gas company to furnish gas at reduced rates; and also that a large saving would result from the joint purchase of material.

NORTH CAROLINA.

The Prevalence of Disease.—During September measles were reported in 8 counties, whooping cough in 18, scarlet fever in 14, diphtheria in 41, typhoid fever in 67, malarial fever in 39 and smallpox in 11.

September Deaths.—During September 214 deaths were reported in the state, equivalent to an annual death rate of 16.9 per 1,000. Diarrheal diseases are reported to have caused 39 deaths; consumption, 23; heart diseases, 15; typhoid fever, 13; brain diseases, 12, and malarial fever, 10.

Society Entertained.—The Buncombe County Medical Society, with a number of invited guests, including prominent members of the profession without the state, as well as distinguished members of the North Carolina profession, were the guests of Dr. James A. Burroughs at his home in Asheville, N. C., November 6.

College Opens.—The fourth annual opening of the medical department of the University of North Carolina took place at Raleigh September 15. The opening address was made by Dr. Hubert A. Royster, dean and professor of gynecology and abdominal surgery. The standard of preliminary education has been advanced. The senior class numbers 10. Dr. William DeB. MacNider has been transferred to the chair of anatomy in the department at Chapel Hill. He continues his instruction in physical diagnosis, however, in the work of the medical department. Dr. R. S. Stevens of Smithfield has been elected to the chair of clinical pathology; Dr. James W. McGee, Jr., Raleigh, advanced from lecturer to professor of pediatrics, and Dr. Robert S. McGeachy, Raleigh, made instructor in therapeutics and anesthetics. The first two years of preparatory work are done at the university proper in Chapel Hill.

NORTH DAKOTA.

Postgraduate School Incorporated.—The Sixth District Postgraduate Medical School of North Dakota has been incorporated at Bismarck.

Personal.—Dr. A. M. McDonald, Grand Forks, has been appointed coroner of Grand Forks County, vice Dr. Herbert W. Matthews, Emerado, resigned.

North Dakota Medical College Opens.—The Medical College of the University of North Dakota, Grand Forks, opened for the year September 26. The university laboratories, equipment and instruction have been so arranged that the B.A. degree of the institution will admit students to the junior year in the medical college.

OREGON.

Personal.—Dr. H. Volp, Pendleton, and family have moved to the East, where he will locate.

Accident.—Dr. Allan Welch Smith, Portland, formerly assistant quarantine physician of Baltimore, Md., recently met with a painful accident while hunting. His rifle was accidentally discharged, the ball passing through the palm of the hand.

New Building for Willamette University.—The new building for the medical department of Willamette University, Salem, is nearing completion and will be ready for occupancy about January 1. It will cost about $15,000, nearly all of which has been subscribed by the people of Salem.

PENNSYLVANIA.

Diphtheria Closes Schools.—Two township schools near McDonald, the Robbs Run school and the Allegheny school, have been closed on acount of diphtheria.

Personal.—Dr. J. Miller Hyson, Red Lion, landed at New York October 14 after a circumnavigation of the globe.——Dr. Frank P. McCarthy, Oil City, has taken a trip to Wyoming.——Dr. Frank B. Statler, Johnstown, who has been seriously ill with typoid fever, is improving.——Dr. Robert G. Barckley, Milford, is recovering from a serious illness.

Donation Day.—At the hospital day exercises in St. Luke's Hospital, South Bethlehem, $5,000 in cash was donated to the institution by Samuel Thomas of Hokendauqua.——At the donation day of Chester Hospital, October 19, great quantities of supplies were given to the institution and cash donations amounting to $839.30 were also made.

Hospital Endowed.—Mrs. Mary Packer Cummings, Mauch Chunk, has agreed to give to the Robert Packer Hospital, which was named for her late brother, Robert A. Packer, Sayre, the income from certain real estate which will amount to more than $3,000 a year, and has also agreed to deed to the hospital ground adjoining the institution when the extension of the institution demands it.

Hospital Staff.—The staff of the Good Samaritan Hospital, Lebanon, is now composed as follows: Chief of staff and consulting physician, Dr. William M. Guilford; attending physicians, Drs. William M. Guilford and Charles M. Strickler; attending surgeons, Drs. John Walter, John Beattie and Alfred S. Weiss; gynecologist and consulting surgeon, Dr. Samuel Weiss; radiologist, Dr. Alfred S. Weiss; eye, ear, nose and throat department, Drs. Frederick S. Kaufman and Warren F. Klein; dispensary physicians, Drs. J. W. Trabert and Harvey E. Maulfair.

Philadelphia.

Bazaar for Hospital.—The board of women visitors of the Hospital of the University of Pennsylvania will give a Christmas bazaar for the benefit of the hospital, in Horticultural Hall, on the afternoons and evenings of November 23-25.

Free Public Lectures.—The Ludwick Institute announces a course of free public lectures on "The Natural Sciences and Their Application."——A series of five lectures is to be delivered by Dr. Henry Skinner on entomology every Monday evening, beginning March 19.

Sanatorium Dedicated.—The dedication exercises of the Pennsylvania Sanatorium, a branch of the Battle Creek institution, were held October 31. Hon. Wilson H. Brown acted as chairman, and the dedicatory address was delivered by Dr. John H. Kellogg, Battle Creek, Mich.

Personal.—Dr. Nathan F. Mossell has been reinstated as medical director of the Frederick Douglas Hospital and Training School. The election of Dr. E. C. Howard as medical director was declared illegal on account of the failure to notify members of the board that an election was to be held.

Hospital Association Election.—The Hospital Association of Philadelphia, at its annual meeting October 27, elected officers for the ensuing year. The association now has a membership of 28. The advisability of providing for an exchange between hospitals as regards chronic patients was considered.

Marine-Hospital Service, in custody of Passed Assistant Surgeon George B. Young, were totally destroyed. Surgeon Young suffered also a personal loss of $1,000.

Asks Large Appropriation.—The board of trustees of the Mississippi State Insane Hospital, Jackson, has decided to ask the legislature for an appropriation of $150,000 for the purpose of erecting new buildings and making necessary improvements. The hospital is now crowded to overflowing and the board desires to have a detached building erected for a hospital and for the treatment of tuberculous patients.

To Examine into Insane Hospital Management.—Governor Vardaman has appointed a commission to examine into the management of the state insane hospitals located at Jackson and Meridian, consisting of Drs. Vardaman S. McLellan, Canton; Donald P. Street, Vicksburg; Ernest Spiva, Sturgis; Jefferson D. Smythe, Greenville; James W. Gray, Jr, Clarksdale; C. H. Ramsey, Collins, and John W. Young, Grenada.

MISSOURI.

Personal.—Dr. August Rhodes, Carthage, is critically ill at his home in that city.

Smallpox Epidemic.—Birchtree and the adjacent portion of Shannon County are suffering severely from a smallpox epidemic. There are reported to be at least 10 cases, and 4 deaths have occurred.

Opposes Club Doctors.—The Jackson County Medical Society adopted a resolution calling on all physicians engaged by lodges, societies and commercial institutions under contract prices, to resign at once under penalty of suspension from the society.

Diphtheria.—During the month of October 47 cases of diphtheria were reported in Kansas City, 14 less than on the corresponding day of 1904.——The board of health has ordered the fumigation of the Horace Mann and Linwood schools, in which districts the disease has been most prevalent.

Patent Medicine Advertisements.—The secretary of the St. Louis Medical Society has written to the city attorney of St. Louis, calling attention to a violation of city ordinances in the advertising of patent medicines. Some advertisements were characterized as obscene. The latter stated that the legislative committee of the society had appointed a committee consisting of Drs. George Homan, John Young Brown and Henry J. Scherck, to co-operate with the city attorney in enforcing a strict observation of the ordinances regarding advertising.

NEW MEXICO.

Hospital Society Organized.—The citizens of Albuquerque, claiming that eastern and western physicians are in the habit of sending dying tuberculous patients to that city, have established an associated charity hospital for those at present in the city, and will engage in a determined effort to put a stop to the practice of sending the hopelessly ill to New Mexico in the future.

Sanatorium to Open.—The New Mexico Cottage Sanatorium, Silver City, is nearly completed and will be open for patients November 25. The institution will be under the personal management of Dr. Earl S. Bullock. It consists of two main buildings and fifteen separate cottages, each of which accommodates one patient. The institution will be devoted exclusively to the care and treatment of cases of laryngeal and pulmonary tuberculosis.

NEW YORK.

Hospital Sunday.—The annual contribution obtained from city churches for the benefit of Ellis Hospital, Schenectady, October 22, amounted to $1,962.41.

Columbia Alumni Organized.—On November 2 the Columbia Alumni Medical Association of Buffalo was organized, with Dr. Carlton R. Jewett, president; Dr. Arthur W. Hurd, vice-president, and Dr. Edwin L. Bebee, secretary and treasurer.

New Hospital Dedicated.—The new building erected and equipped by Mr. and Mrs. Frederick P. Proctor at Utica at a cost of about $360,000, was formally dedicated and consecrated October 18. The hospital will accommodate 175 patients.

Memorial Hospital Building.—Mrs. G. D. B. Bonbright and Mrs. Robert Bartlett, daughters of the late James C. Hart, will erect a large addition to the Rochester City Hospital as a memorial to their father. The building will cost about $50,000 and will be three stories in height.

Medical Board Elected.—Dr. Joseph B. Hulett has been elected president; Dr. J. LaT. Hanmer, vice-president, and Dr. Edwin M. Schultz, secretary and treasurer, of the medical board of Thrall Hospital, at Middletown. The resignation of Dr. Edwin Fancher of the attending board was accepted and he was elected a member of the consulting board.

Northern New York Physicians.—The Medical Association of Northern New York met in Malone October 24 and elected the following officers: President, Dr. E. S. McClellan, Saranac Lake; vice-president, Dr. William C. Smith, Winthrop; secretary, Dr. Alfred G. Wilding, Malone, and treasurer, Dr. George H. Oliver, Malone. The association will meet in Malone next year.

Visitors to State Hospital.—The State Hospital, Buffalo, was visited October 23 by a royal commission of English visitors and philanthropists, who are making a tour of investigation of the institutions for the care and control of the feeble-minded in the United States. The commission was made up of W. B. Byrne, C.B., W. H. Dickinson, H. B. Donkin, F.R.C.P., J. D. Dunlop, F.R.C.P., and Mrs. Hume Pinsent.

Diphtheria.—Diphtheria is reported epidemic in Charlotte, and strict quarantine is being observed.——Public schools 59, 60, 64 and 65 of Brooklyn have been ordered closed pending official investigation of diphtheria which is prevalent in that section.——The public schools of Union Course have been ordered closed by the health department because the residents of that section would not allow the health inspectors to examine their children.

Central New York Physicians.—The Medical Association of Central New York held its thirty-eighth annual meeting in Buffalo October 24. Among the papers read was one on bony atrophy by Dr. Louis A. Weigel, Rochester, who as the result of his researches into the employment of *x*-rays, recently lost his right arm and three fingers of his left hand. The following officers were elected: President, Dr. David M. Totman, Syracuse; vice-presidents, Drs. William B. Jones, Rochester, and Lemuel L. Tozier, Batavia; secretary, Dr. Clarence A. Greenleaf, Rochester, and treasurer, Dr. William M. Brown, Rochester.

Personal.—Dr. Robert Frazer of the staff of the Riverside Accident Hospital, Buffalo, was operated on October 17 for appendicitis, and is reported as improving.——Dr. Max C. Breuer and family, Buffalo, returned from Europe October 21.——Dr. Fred M. Barney, Dolgeville, has received a government appointment in Cuba.——Dr. James E. O'Malley, Newburgh, who has been confined to his home for some time as the result of a broken patella, has resumed practice.——Dr. George H. Torney, first assistant physician at the State Hospital, Utica, has gone to California for a visit.——Dr. Douglas A. White, superintendent of the Hospital of the Good Shepherd, Syracuse, has resigned, to take effect December 1.——Bert E. Nelson has been appointed bacteriologist of the board of health of Binghamton.——Dr. Warren B. Stone has been appointed bacteriologist of Schenectady, vice Dr. Norman B. Saunders, removed from the city.——Dr. Henry H. Davidson, Northport, formerly coroner of Suffolk County, fell October 24 while walking across his office and fractured his hip.

New York City.

Home for Consumptives.—Under the direction of the *Tribune* Sunshine Society, Dr. James S. Ennis is to establish a Home for Consumptives in Florida.

New York Surgical Society.—At the annual meeting of this society November 8 the following officers were elected: President, Dr. George Woolsey; vice-president, Dr. Joseph A. Blake, and secretary and treasurer, Dr. John A. Hartwell.

Personal.—Dr. William J. Robinson, editor of the *Medico-Pharmaceutical Critic and Guide*, has returned from Europe after an absence of nine months.——Drs. Murray M. Rarick and W. E. Lippold have been appointed house surgeons and Dr. E. J. Dorn, ambulance surgeon, at the Williamsburg Hospital.

Signed False Death Certificate.—Dr. George E. Morgan, who in July last gave a certificate of the death of Mamie Jeanette Thompson, certifying that she had died from tumor, pleaded guilty November 8 to having falsely signed a death certificate and was sentenced to ten days' imprisonment in the Tombs and to a fine of $200.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 4, 363 cases of tuberculosis, with 150 deaths; 279 cases of diphtheria, with 22 deaths; 169 cases of measles, with 5 deaths; 77 cases of typhoid fever, with 11 deaths; 79 cases of scarlet fever, with 6 deaths; 9 cases of cerebrospinal meningitis, with 15 deaths, and 132 cases of chickenpox.

Hospitals Benefit.—A bazaar given at the Waldorf-Astoria on November 8 netted $6,000 for the Hospital for Crippled

Children.——The late Miss Margarette A. Jones has left the Postgraduate, St. Luke's and the Presbyterian hospitals a bequest which will give to each institution more than $200,000, the income of which is to be devoted to the care of poor patients.——The late John Inglis has left the Presbyterian Hospital $1,000.——By the will of Rebecca M. St. John the Northern Dispensary of New York will receive $3,000.

Hospital News.—The new wing of St. Vincent's Hospital, Manhattan, was formally opened November 1. The new building is seven stories high and has accommodation for 100 patients. It is fireproof and is thoroughly equipped.——Certificate of incorporation has been filed with the secretary of state by St. Joseph's Hospital, Far Rockaway, for the maintenance of a general hospital.——Bensonhurst Sanatorium Company has been incorporated in Brooklyn, with a capital stock of $100,000, by Dr. Earl H. Mayne and others.——The new Washington Heights Hospital was formally dedicated October 15.

Home Cure of Consumption.—The College of Physicians and Surgeons, Columbia University, announces favorable results of a plan for the cure of tuberculosis which has been employed in an experimental way for the past two years. This plan consists in treating the patient at the clinic and his home. Advice is given both verbally and on printed slips, instructing him how to live a sanitary life, and medicine is furnished when necessary. Each patient is placed in the care of a visiting nurse, who reports to the physician the conditions found at the home. During the two years in which the plan has been in operation there have usually been about 100 cases under treatment at one time. During the past year 408 patients were treated and 2,746 visits were made by the nurse.

Hospitals Wasteful.—The report of the findings of the committee on hospital needs and hospital finances, which has been at work since March of this year, states that the private hospitals of New York are extravagant in the use of costly drugs and dressings and that they do not receive the support from charitable persons that their work deserves. This committee is composed of men of large hospital experience and responsibility, who suggest that there should be uniformity in keeping accounts and making reports of work done, as the public has a right to know that hospitals are run under the most economical basis consistent with efficiency in treatment. The committee also suggests that the hospitals co-operate and purchase coal "in cargo" and that by similar co-operation they might be able to compel the gas company to furnish gas at reduced rates; and also that a large saving would result from the joint purchase of material.

NORTH CAROLINA.

The Prevalence of Disease.—During September measles were reported in 8 counties, whooping cough in 18, scarlet fever in 14, diphtheria in 41, typhoid fever in 67, malarial fever in 39 and smallpox in 11.

September Deaths.—During September 214 deaths were reported in the state, equivalent to an annual death rate of 16.9 per 1,000. Diarrheal diseases are reported to have caused 39 deaths; consumption, 23; heart diseases, 15; typhoid fever, 13; brain diseases, 12, and malarial fever, 10.

Society Entertained.—The Buncombe County Medical Society, with a number of invited guests, including prominent members of the profession without the state, as well as distinguished members of the North Carolina profession, were the guests of Dr. James A. Burroughs at his home in Asheville, N. C., November 6.

College Opens.—The fourth annual opening of the medical department of the University of North Carolina took place at Raleigh September 15. The opening address was made by Dr. Hubert A. Royster, dean and professor of gynecology and abdominal surgery. The standard of preliminary education has been advanced. The senior class numbers 10. Dr. William DeB. MacNider has been transferred to the chair of anatomy in the department at Chapel Hill. He continues his instruction in physical diagnosis, however, in the work of the medical department. Dr. R. S. Stevens of Smithfield has been elected to the chair of clinical pathology; Dr. James W. McGee, Jr., Raleigh, advanced from lecturer to professor of pediatrics, and Dr. Robert S. McGeachy, Raleigh, made instructor in therapeutics and anesthetics. The first two years of preparatory work are done at the university proper in Chapel Hill.

NORTH DAKOTA.

Postgraduate School Incorporated.—The Sixth District Postgraduate Medical School of North Dakota has been incorporated at Bismarck.

Personal.—Dr. A. M. McDonald, Grand Forks, has been appointed coroner of Grand Forks County, vice Dr. Herbert W. Matthews, Emerado, resigned.

North Dakota Medical College Opens.—The Medical College of the University of North Dakota, Grand Forks, opened for the year September 26. The university laboratories, equipment and instruction have been so arranged that the B.A. degree of the institution will admit students to the junior year in the medical college.

OREGON.

Personal.—Dr. H. Volp, Pendleton, and family have moved to the East, where he will locate.

Accident.—Dr. Allan Welch Smith, Portland, formerly assistant quarantine physician of Baltimore, Md., recently met with a painful accident while hunting. His rifle was accidentally discharged, the ball passing through the palm of the hand.

New Building for Willamette University.—The new building for the medical department of Willamette University, Salem, is nearing completion and will be ready for occupancy about January 1. It will cost about $15,000, nearly all of which has been subscribed by the people of Salem.

PENNSYLVANIA.

Diphtheria Closes Schools.—Two township schools near McDonald, the Robbs Run school and the Allegheny school, have been closed on acount of diphtheria.

Personal.—Dr. J. Miller Hyson, Red Lion, landed at New York October 14 after a circumnavigation of the globe.——Dr. Frank P. McCarthy, Oil City, has taken a trip to Wyoming.——Dr. Frank B. Statler, Johnstown, who has been seriously ill with typoid fever, is improving.——Dr. Robert G. Barckley, Milford, is recovering from a serious illness.

Donation Day.—At the hospital day exercises in St. Luke's Hospital, South Bethlehem, $5,000 in cash was donated to the institution by Samuel Thomas of Hokendauqua.——At the donation day of Chester Hospital, October 19, great quantities of supplies were given to the institution and cash donations amounting to $839.30 were also made.

Hospital Endowed.—Mrs. Mary Packer Cummings, Mauch Chunk, has agreed to give to the Robert Packer Hospital, which was named for her late brother, Robert A. Packer, Sayre, the income from certain real estate which will amount to more than $3,000 a year, and has also agreed to deed to the hospital ground adjoining the institution when the extension of the institution demands it.

Hospital Staff.—The staff of the Good Samaritan Hospital, Lebanon, is now composed as follows: Chief of staff and consulting physician, Dr. William M. Guilford; attending physicians, Drs. William M. Guilford and Charles M. Strickler; attending surgeons, Drs. John Walter, John Beattie and Alfred S. Weiss; gynecologist and consulting surgeon, Dr. Samuel Weiss; radiologist, Dr. Alfred S. Weiss; eye, ear, nose and throat department, Drs. Frederick S. Kaufman and Warren F. Klein; dispensary physicians, Drs. J. W. Trabert and Harvey E. Maulfair.

Philadelphia.

Bazaar for Hospital.—The board of women visitors of the Hospital of the University of Pennsylvania will give a Christmas bazaar for the benefit of the hospital, in Horticultural Hall, on the afternoons and evenings of November 23-25.

Free Public Lectures.—The Ludwick Institute announces a course of free public lectures on "The Natural Sciences and Their Application."——A series of five lectures is to be delivered by Dr. Henry Skinner on entomology every Monday evening, beginning March 19.

Sanatorium Dedicated.—The dedication exercises of the Pennsylvania Sanatorium, a branch of the Battle Creek institution, were held October 31. Hon. Wilson H. Brown acted as chairman, and the dedicatory address was delivered by Dr. John H. Kellogg, Battle Creek, Mich.

Personal.—Dr. Nathan F. Mossell has been reinstated as medical director of the Frederick Douglas Hospital and Training School. The election of Dr. E. C. Howard as medical director was declared illegal on account of the failure to notify members of the board that an election was to be held.

Hospital Association Election.—The Hospital Association of Philadelphia, at its annual meeting October 27, elected officers for the ensuing year. The association now has a membership of 28. The advisability of providing for an exchange between hospitals as regards chronic patients was considered.

Money for Health Department.—The councils committee on public health and charities has recommended an appropriation of $650,496 for the year 1906. Of this amount $285,156 is required for the maintenance of the Philadelphia Hospital and $80,140 for expenses of the office of director of public health and charities.

Hospital Reports.—The additional reports of the hospitals for October show that 58 patients were under treatment in the Kensington Hospital for Women; that 67 operations were performed, and that 36 new patients and 137 old patients were treated in the dispensary.——The report of the Medico-Chirurgical Hospital shows that 7,492 patients were treated.

Reading Relief Report.—The statement for the month of September, 1905, of the Philadelphia & Reading Relief Association shows an expenditure of $23,009.40, out of which $12,300 was paid for deaths and $10,709.40 for disability. The number of deaths was 23, of which 12 were from accidental and 11 from natural causes; 1,109 new cases were reported.

Internes Will Get Their Deposits.—The fourteen physicians who occupied positions as internes at the Philadelphia Hospital in 1903 and who each paid a deposit of $100, will receive their deposits as soon as the estate of the late superintendent of the hospital can be audited by the court. The deposit is required from each interne as a guarantee against loss by breakage of apparatus.

Medical Inspection in October.—The report of the division of medical inspection of the Bureau of Health for the month of October shows that 6,020 inspections were made, excluding schools; 506 fumigations were ordered, and 11 cases were presented for special diagnosis. The inspectors made 5,351 visits in the schools and excluded 877 children from attendance; 84 cultures were collected; 81 injections of antitoxin were given and 1,120 vaccinations were performed.

Bequests.—By the will of Sue M. Remak the German and Episcopal hospitals receive $100 each.——By the will of Miss Marie E. Brasier St. Joseph's Hospital receives $5,000 for a free bed in memory of Charles A. Brazier, and $5,000 for a bed in memory of Elizabeth P. Brazier. She also bequeathes to the same institution certain real estate and moneys derived from other real estate. The will also devises $10,000 to St. Vincent's Home and Maternity Hospital; $3,000 to the Sisters of St. Francis for the maintenance and support of St. Mary's Hospital——The Mount Sinai Hospital is devised $100 in the will of the late George Finkelstein.

Health Report.—The deaths for the week aggregated 438. This is an increase of 44 over the number reported last week, and an increase of 15 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 6; whooping cough, 4; diphtheria, 9; tuberculosis, 57; cancer, 26; diabetes, 6; apoplexy, 14; heart disease, 41; acute respiratory disease, 42; enteritis, 19; Bright's disease, 46; suicide, 5; accidents, 25; marasmus, 9. There were 251 cases of contagious diseases reported, with 18 deaths, as compared with 178 cases and 17 deaths for the previous week, an increase of 73 cases of contagious disease for the week.

Vital Statistics.—The report of the division of vital statistics of the health bureau for October shows that 1,580 deaths, 2,800 births and 963 marriages were reported. The report of the division of milk inspection shows that 5,200 examinations were made aggregating 116,954 quarts, and that 508 quarts were condemned. There were made 937 microscopic and 5 chemical examinations. The report of the bacteriologic laboratory reveals that 775 diphtheria cultures were examined; 415 specimens of blood for typhoid fever; 950 specimens of milk were analyzed bacteriologically; 111 specimens of sputum were investigated, and 8 disinfection tests were performed. The report further shows that 2,513,700 units of antitoxin were distributed. The chemical laboratory reported 95 analyses.

UTAH.

State Building Condemned.—It is reported that one of the most costly of the buildings occupied by the State Mental Hospital, which was constructed only two years ago at a cost of $30,000, has been condemned as unsafe and likely to collapse at any time.

Health Officers Confer.—At the session of the Association of Health Authorities of Utah, held in Salt Lake City, the following officers were elected: Dr. John S. Gordon, Ogden, president; Dr. Fred W. Taylor, Provo, vice-president; Horace Smith, Salt Lake City, secretary, and Dr. David O. Miner, Nephi, treasurer.

WISCONSIN.

Smallpox in State Institution.—On account of 10 cases of smallpox discovered among the students of the State Institute for the Blind, Janesville, the institution has been placed under strict quarantine.

Diphtheria.—Washington Harbor schools and churches have been closed and strict quarantine is being maintained on account of an epidemic of diphtheria on Washington Island.——The public school of Eland has been closed on account of diphtheria.

Unlicensed Practitioner Arrested.—Arthur Budan, Milwaukee, was arrested October 3 on a warrant sworn out by the secretary of the State Board of Medical Examiners, charged with practicing medicine without a license. Budan was arrested on a similar charge about a year ago. He claimed to be a graduate of the Harvey Medical College of Chicago, which is not recognized by the state board.

Personal.—Dr. John Van R. Lyman, Eau Claire, has returned from Europe.——Dr. J. Fremont Corbett, Weyauwega, has gone to Southern California for his health.——Dr. H. H. Williams, Sparta, has moved to Colorado.——Dr. Otto B. Bock, Sheboygan, has been appointed assistant surgeon of the Wisconsin National Guard, with the rank of first lieutenant, and has been assigned to the Second Infantry.——Dr. Thomas Fitzgibbon, Milwaukee, returned from Europe October 28.——Dr. John W. Coon has been made superintendent of the Milwaukee County Hospital, vice Dr. Ernest C. Grosskopf.

Must Report Accidents.—The new law, which went into effect November 1, provides that:

> It shall be the duty of any physician to report any accident to any person whom he shall be called on to care for professionally when such person is thereby incapacitated for pursuing his usual vocation for a period of at least two weeks. The cause, nature, and results of such accident, the place where and the condition of the person at the time it occurred shall be fully described in the report of said physician. The returns of such accident shall be made by the physician and by the public officer, and the fees therefor and the penalties for non-compliance on the part of either the physician or the public officer, shall be the same as in cases of births and deaths.

GENERAL.

Plague in Hawaii.—Dr. Hobdy of the United States Public Health and Marine-Hospital Service reports 2 deaths from plague at Honolulu, October 30.

Malaria on the Isthmus.—It is reported that malaria is prevalent among the laborers on the canal and among the population of Colon and Cristobal. Among the greatest sufferers are the recently arrived laborers from Barbadoes and the West Indies.

The Medical News Absorbed.—It is announced that the A. R. Elliott Company has purchased the *Medical News* of New York City and will consolidate it with the *New York Medical Journal*, Jan. 1, 1906. It will be a regret to those who have appreciated the *Medical News* to have it disappear from the ranks of eastern journalism. It has been understood that since the removal of the *Medical News* to New York it has been gradually losing ground, a fact not at all due to any lack of able editorial supervision or good material furnished in its reading pages. The *Medical News* has stood for high-class journalism, and it is hoped that all its good features will be retained by the purchasers.

Medicolegal Papers Wanted for International Congress.—The committee in charge of the International Medical Congress, which will be held in Lisbon from April 19 to 26, 1906, has written asking for the contribution of papers on the following subjects and their medicolegal relations, and saying that as yet no titles of communications touching on any of these subjects have been received from this country:

The signs of virginity and defloration.
Handmarks and finger prints.
The mechanism of death by hanging.
The value of bacteriologic examination of vulvo-vaginal discharges in the determination of venereal contagion.
The signs of death by drowning.
Ecchymoses.
Spontaneous and criminal abortions.
Blood stains.
The relations between the seat of cerebral contusions and the point of application of the agent which produced them.
Epilepsy.
When is the induction of abortion permissible?
The best legislation for the protection of the "medical secret."
The effects of the civil and penal law toward the newborn living infant.
Organization of medicolegal services.

Any who intend to take part in the discussions of this section, or to prepare papers on these or other subjects, should inform the secretary of the American committee, Dr. Ramon Guiteras, 75 West Fifty-fifth Street, New York.

Women Nurses for the Navy.—Surgeon-General Rixey advocates the employment of women nurses in the navy. The medical department of the army is provided with a corps of trained women nurses, and their adaptability to service conditions and efficiency in institutions under military control have been fully established. Their services, says Dr. Rixey, would be useful in the naval hospitals, insuring for the sick of the navy as careful nursing as is now given to the sick of the army. Women nurses would also be of value in teaching and training the men of the hospital corps, and, in the event of war, besides being utilized on hospital ships, they could, in large part, take the place of the men in the naval hospitals, thereby releasing the latter for service with the force afloat.

Health Report of the Philippines.—The report of the Board of Health of the Philippine Islands for July states that 644 children were born in Manila during the month, a birth rate of 34.49 per 1,000 inhabitants. Seven hundred and ninety-five deaths were reported; of these 747 were residents and the others transients. There were 140 deaths from convulsions of children under 5 years of age, and 107 from pulmonary tuberculosis. Diarrhea and enteritis caused 85 deaths of children under 2 years of age and 52 deaths of older individuals. There were 3 deaths from bubonic plague.

Epilepsy Association to Meet.—The fifth annual meeting of the National Association for the Study of Epilepsy, etc., will be held at the Academy of Medicine, 17 Forty-third Street, New York City, the afternoon and evening of November 29. All persons interested are invited. The program includes the following subjects and authors:

Reports on Progress in the Public Care of Epileptics in New Jersey,, Dr. H. M. Weeks, Skillman; in Kansas, Dr. L. M. Perry, Parsons; in Texas, Dr. John O. Preston, Abilene; in Indiana, Hon. Ezra Mattingly, Washington; in Australia, Miss Alice Henry, England.

Organic Epilepsy, Drs. D. R. Brower, Chicago, and Morgan B. Hodskins, Palmer, Mass.

The Management of the Individual Epileptic, Dr. Edgar J. Spratling, Forsyth, Ga.

Value of Hydrotherapy in Epilepsy, Dr. Guy Hinsdale, Hot Springs, Va.

Can a Colony for Epileptics be [illegible] and, if so, How? Dr. Thos. C. FitzSimons, [illegible]

Blood Pressure Observations in [illegible] rd A. Kennedy, Palmer, Mass.

Epileptic Automatism, Dr. Edward Cowles, Boston.

Traumatic Psychic Epilepsy, Dr. Pearce Bailey, New York City.

Hospital Care and Treatment of Epileptics. Dr. Arthur O. Morton, Palmer, Mass.

Cases will be reported by Dr. Everett Flood, Palmer, Mass. Secretary of the association and by Drs. Matthew Woods, Philadelphia; N. B. Ross, Sonyea, N. Y.; W. P. Spratling, Sonyea, N. Y., and W. G. Chase, Boston.

Yellow Fever News.—In all, New Orleans has had 3,400 cases of yellow fever, with 451 deaths, a mortality of 13.26 per cent. At the present time there are only four or five cases under treatment.——Vicksburg reports that its epidemic expenses were between $15,000 and $20,000.——At Pensacola conditions are greatly improved, less than 40 cases being under treatment. In all, Pensacola has had over 560 cases, with some 80 deaths, a death rate of 14.28 per cent.——Charleston, S. C., on October 30 abandoned its quarantine.——One of the most serious sequels of the epidemic in New Orleans is now to the fore. On November 5 it was announced that Dr. Joseph Holt, who for years was president of the Louisiana Board of Health, had issued a circular letter making very grave charges against Dr. E. Souchon, president of the Louisiana State Board of Health, and Dr. Quitman Kohnke, health officer of New Orleans. Their conduct of the early days of the epidemic is directly attacked and their motives are impugned. This scandal threatened to raise its head during the epidemic. Now it evidently must be thrashed out to a finish, until reputations are cleared of suspicion. It is very unfortunate and yet full investigation will for all parties be preferable to repetition of gossip and scandal.——Later and more reliable reports from Natchez indicate that the city did not have a non-intercourse system, but a rigid exclusion of people from infected points, others being admitted by certificate. Almost from the beginning the Adams County Medical Society appointed a committee of seven, which acted as an advisory board of health.——On November 10, though nearly all quarantines are down, the press published a queer story of the detention by the Texas authorities of Miss Dorothy Tennant and her entire "College Widow" Company. They are said to have been appearing in towns that have not been infected, and, according to the story, a strong protest is being made, especially at the prospect of the company living a week in quarters recently tenanted by negroes and Italians.——Havana, Cuba, on November 10 reported 2 cases of yellow fever, both of the patients being alleged to be recent arrivals from New York. Evidently a different explanation will come later.

FOREIGN.

The Chair of Obstetrics at Edinburgh.—The curators of Edinburgh University have appointed Sir Halliday Croom to succeed Professor Simpson as teacher of obstetrics in that institution.

Supposed Yellow Fever Scare in Cuba.—A case supposed to be yellow fever was reported from Guantanamo; the patient died and the autopsy showed gastric ulcer and chronic nephritis, but no lesions of yellow fever.

The Medical Mayor of Lyons Appointed Governor of Madagascar.—Dr. Augagneur has been mayor of Lyons for several years and has made a fine record for his administration. His innovations and the energy with which he conducts affairs have long won for him in Lyons the title of the "emperor." We learn that he has recently accepted the position of governor of Madagascar.

The Virchow Monument in Berlin.—The memorial to Virchow is to be erected on the Karlsplatz, and $16,000 are already in hand for the purpose. Nearly half this amount was raised by subscription, the municipality making up the balance. Prizes of $600, $400 and $200 have been appropriated for the most suitable design for the memorial, the artists being left unrestricted as to style and size.

Congress of Criminal Anthropology.—The sixth Italian Congress of Criminal Anthropology is to convene at Turin April 26, 1906. There will be an exhibition in connection with the congress, and the friends and admirers of Professor Lombroso are planning a public manifestation in his honor on the occasion. A committee has the matter in charge; the chairman is Professor Pagliani, president of the medical faculty of the University of Turin.

Ewald Festival Number of Berliner klin. Wochenschrift.—Prof. C. A. Ewald has been connected as editor with the *Berliner klinische Wochenschrift* for twenty-five years, sharing the editorial responsibility with Prof. C. Posner. On the occasion of his sixtieth birthday, October 30, a special festival number was issued dedicated to him. It contains over 132 pages, while the weekly issue is generally from 18 to 26 pages. Twenty-eight articles are contributed by friends or former pupils and thirteen more by workers in the hospital under his charge. The dedication refers to the beautiful German custom of celebrating in this way the decennial anniversaries of its scientific leaders. It is assumed that a scientist and instructor will be most pleased and proud to be presented with the evidences of serious work done by those who stand the closest to him, scientific communications from his pupils who have received the stamp of his own spirit. "Such a *Festschrift* or *Festnummer* reflects the personality and the worth of the one thus honored better than any other tribute that could be offered." Two at least of the articles in the *Festnummer* are from America.

Italian Congress for Internal Medicine—Phenic Acid Treatment of Tetanus.—This congress (the fifteenth) was held at Genoa, October 24-29. The chief subjects were: "Etiology of Malaria," "Anemia of Parasitic Origin," and "Surgical Treatment of Gastrointestinal Affections." Great interest was aroused by the favorable statistics presented by Baccelli in regard to his method of treating tetanus by subcutaneous injections of phenic acid. Behring has reported a mortality of 44 per cent. with his serum, and Tizzoni 30 per cent. with his, but Baccelli's method has had a mortality of only 10 per cent. in 200 cases, while Woods has had only one death among 34 patients thus treated. Babes' research on dogs, rabbits and pigeons has confirmed the positive action of phenic acid on experimental tetanus. Baccelli proclaims that phenic acid is not only a powerful moderator of the reflexes, but also an excellent antithermic and good antitoxic. The perfect tolerance for it of the most seriously affected patients he regards as a proof that it is needed. "The tolerance for the remedy is directly proportional to the indication for it." He never gives more than 1 gm. or at most 1.5 gm. per day. Queirolo's experience has confirmed Baccelli's. He gives .5 gm. to .7 gm. a day and has never noted any inconveniences nor the slightest kidney disturbance. Ascoli stated that he had kept close watch of all the cases treated by Baccelli, and had become thoroughly convinced of the value of the treatment. As much as .5 gm. should be given without hesitation, pushing to .7 or .8 gm. if necessary, supervising the urine. He added that, when used in treating neuralgia and myalgia, doses up to 0.1 gm. a day should be currently injected. Its success in these affections was what impelled a trial in tetanus. All the speakers agreed that, except in the fulminating or extremely rapid cases of tetanus, the phenic-acid treatment gives results superior to those realized by any other technic to date.

THE SENN BANQUET

TESTIMONIAL BANQUET AND PRESENTATION OF MEDALLION AND LOVING CUP—A SPLENDID TRIBUTE OF PRAISE AND ESTEEM FROM THE MEDICAL PROFESSION

A testimonial banquet was given to Dr. Nicholas Senn, *Chicago, at the Auditorium Hotel, Saturday evening, Nov. 11,* 1905.

There was an attendance of 686, and from forty to fifty physicians, approximately, were turned away because proper accommodations could not be provided for them—a matter of great regret to the committee of arrangements. There were representatives present from twenty states. Dr. William A. Evans, Chicago, acted as toastmaster. Messages of congratulations were read from several prominent physicians in different parts of the United States, who regretted their inability to attend this notable event.

Dr. Joseph D. Bryant, New York City, presented a gold medallion to Dr. Senn, miniature replicas of which were distributed among those in attendance. On one side of the medallion was a likeness of Dr. Senn; on the other the inscription: "To Nicholas Senn, the Master Surgeon, from his Fellows, November 11, 1905." Dr. L. G. Nolte, Milwaukee, Wis., presented Dr. Senn with a silver loving cup, given by his former private pupils.

Between the speeches were interspersed musical selections by the Swiss Quartette and singing by the banqueters, Dr. Norval H. Pierce leading. Drs. Fernand Henrotin, Daniel R. Brower, Jacob Lang, and William E. Quine related very amusing and interesting anecdotes about Dr. Senn. Addresses were made by Drs. Witherspoon and McMurtry.

The occasion was a memorable one. Good fellowship prevailed, and Dr. Senn, the center of attraction, received a tremendous ovation.

This Banquet One of a Series.

Toastmaster Evans, after calling the meeting to order, said that, in a certain sense, this testimonial to Professor Senn is not the result of Chicago effort, but represents the spontaneous sentiment of the profession of the Mississippi Valley. Viewing the matter from that standpoint, he said there was no reason why a word of welcome should not be said to any man within the sound of his voice. But, on the other hand, there are many men who have journeyed to Chicago from afar in order to add their testimony, their presence, and their words to the testimonial that is given by those who live in the city of Chicago. In behalf of the central committee of arrangements, he extended a welcome to the visiting physicians from the Mississippi Valley, from the eastern seaboard, from the gulf states, and from the states of the Pacific. While Professor Senn is the beneficiary of this meeting, we are no less gainers by it. This is a series of banquets started some years ago, and there are hundreds present who remember how a similar banquet served to sustain the declining years of a man whom the profession all honored, and there are those who every day make acknowledgement of the fact that at that selfsame moment this section of the country was made a better land to live in and a better land in which to practice medicine. Dr. Evans referred to the banquets given to Christian Fenger and N. S. Davis, after which he introduced Dr. Joseph D. Bryant, New York City, who presented Dr. Senn with the gold medallion.

Presentation of the Medallion.

DR. BRYANT said that he knew of nothing that gives him greater comfort than to be able to fulfill the humble position that he was requested to do, the opportunity of spanning, by a few sincere, honest words of affection and praise, the brief interval between the bestowal of a token of distinguished regard and its acceptance by Dr. Senn, whom the profession so much delight to honor. It is fitting that one whose professional career began about the time of that of Dr. Senn should be chosen for this gracious purpose; one whose effort to emulate his achievements added much to the total of his own; one whose respect for him, begotten of years of friendly intercourse, has deposited in his heart a regard for him that knoweth no abatement.

Along the pathway of medical endeavor for nearly a quarter of a century noted and enduring examples illustrative of the wise forethought and generous co-operation are seen in the cause of advanced standing. Instances of his surgical technic foretell notable results that now proclaimed great surgical triumphs. The organization of military medicine, of no recent date, has yielded an abundant harvest because of his early conceptions and continued earnest culture. The books made by him, those given by him, will testify, respectively, to the bright sunshine of active life and the somber shadow of recollection. Human afflictions, which before his time yielded only to indomitable fate, now yield to the outcome of the inspiration of his teaching and the handiwork of his technic. Long-deferred and defeated hopes are now revealed in the happy opportunities contributed by the saving graces of reparative wisdom and skill of which he has given the lion's share.

Dr. Senn is classed a distinguished man, a distinguished surgeon—distinguished not only because of his surgical attainments, but because of the high standard of his ethical instincts and ennobling attributes of a generous nature. May I not, at this time, as a humble servant of joyous friends, present to him, in their behalf, this beautiful symbol of the love and respect which they cherish for him; the likeness of a sterling man, embossed on pure gold, and bearing the legend of true distinction? (Here Dr. Bryant presented Dr. Senn with a gold medallion, the audience arose, waved handkerchiefs and cheered lustily.)

He expressed the hope that this token, emblematic of that which is noblest in human character, may serve to admonish doubting souls to strive for the highest and best of aims. (Applause.)

Loving Cup Presented.

The next speaker introduced was Dr. L. G. Nolte, Milwaukee, Wis., who presented a silver loving cup in behalf of Dr. Senn's former private students, and in so doing said: "As a token of love and affection, Dr. Senn, I present you with this cup (handing the cup to Dr. Senn), the emblem of love, and wish you a great many more years of usefulness, and trust that you may spend the afternoon of your life in good health." (Applause.)

At this juncture, at the suggestion of a South Dakota physician, who was unable to be present, the toastmaster requested the audience to rise and drink a toast to the late Christian Fenger, the teacher of Nicholas Senn, which was accordingly done.

Dr. Senn's Reply.

The toastmaster then introduced Dr. Senn, who was enthusiastically received. He rose amid the waving of handkerchiefs and hearty cheers, and when quiet was restored said, among other things: "I accept from your hands, Dr. Bryant, this beautiful medallion, and assure you that I would rather accept it from your hands than from the hands of any one I know of. I appreciate this tribute. I value it much more highly than I would a decoration by a royal hand." (Applause.) "That means the judgment of one man. This is an expression of love, respect and good wishes of the noblest of all professions." (Applause.) "There are two things in this world, Dr. Bryant, that have always an intrinsic value; one is labor, the other is gold. This medallion will be cherished and highly valued as a souvenir of this memorable gathering. It is to me an evidence that my labors, arduous as they may have been, have not been entirely in vain. I thank you, Dr. Bryant, for your presence and for your eloquent address. I wish also to thank Dr. Nolte as the spokesman of my old students, and wish to tell him that I may have been in the past a somewhat severe master; I may have seemed to my students unjust at times (cries of never, never). But let me say to you I have never asked a student to do what I would not do myself." (Applause.)

Dr. Senn then read a poem, the text of which, he said, was taken from one of the most famous of the ancient philosophers—Seneca. The title of the poem was "For Life is Short, and Art is Long."

In conclusion, Dr. Senn said: "Let me return my heartiest thanks, first, to the members of the committee of arrangements, and particularly to Dr. Evans. I thank all the gentlemen who have come from afar to bring me tributes from the profession. I thank the Swiss choir for their sweet songs, and I thank each one of you for your presence, for your friendship, for your respect, and for your good wishes." (Loud and prolonged applause.)

Mayo on "American Surgery."

The next speaker was Dr. William J. Mayo, Rochester, Minn., who spoke to the toast, "American Surgery." Dr. Mayo said that there is a surgery in this country that is so typical and characteristic that it can be said to be "American surgery." There was a time in which it did not exist. Twenty years ago the surgery of the United States of America was the surgery of the world, based on clinical observation and a most inadequate pathologic foundation. The early contributions to surgery in America did not come entirely from the seacoast cities, although great and noteworthy were they, but they came from this country as a whole. Bigelow, Mott, Morton and many others from the seacoast did most notable things; but we must recollect that Sims, Battey and McDowell came from the South; and we had, in Indianapolis, Bobbs, who did the first operation on the gall bladder, and Connors, who first removed the stomach in the Mississippi Valley. We had Wolcott, of Milwaukee, who operated first on the kidney; then we had Brainard and Gunn and Edmund Andrews, of Chicago. But twenty years ago we were behind in surgical pathology. Here and there men of European education had come to this country and established spheres of influence for scientific work. The work of Fenger, of Chicago; Lange, of New York, and others, while to a certain extent local in character, was of incalculable benefit to the people of the entire country. The mass of the profession of this country twenty years ago were behind the Germans in pathology. Germany in scientific surgery had passed us by. The mass of the profession in this country did not know the position they occupied until Senn's "Principles of Surgery" was published. (Applause.) This book was popular. It had its effect in diffusing knowledge and surgery in this country became instantaneous. This book did more to teach the profession how little they knew and how much that was being accomplished than any one thing that had happened. Following this were notable contributions to surgical pathology by Roswell Park, by John Collins Warren, of Boston, and others. At about this time there also appeared the great book of Gerster. It taught the profession how to apply the new knowledge which Senn, Fenger and others had brought forth. There appeared at this time, too, a series of letters from abroad, published in The Journal of the American Medical Association, and written by Senn, describing in clear-cut, forcible language the conditions as they actually existed in German clinics. These letters told the profession what they did, what they thought, and how they did it. Dr. Senn had written up the work of these men in such an absorbing and fascinating style that every man felt as though he himself had visited these clinics, and had seen these men work. These letters were a stimulus for every medical student, who desired to do surgery, to go to Germany or be drawn there as by a magnet. Every man who did surgery felt he could not do justice to his patients if he had not been abroad, and consequently he slaved and saved for the purpose. Multitudes of American students went to Germany, so that there were more medical students in Germany than in all the other foreign countries combined. American surgery was soon Germanized in the United States under the leadership of Dr. Senn. In ten years America was Germanized in surgical pathology. American students, who had attended German clinics, brought back what was best in each one and all of this was grafted on American surgery. In America, more than in any other place, there is now taught what may be called a living pathology. The scientific German accepts little that does not emanate from the deadhouse or does not come from the laboratory.

Another characteristic in this country which has been carried out more thoroughly than in any other place abroad is this: We see borderline cases in which the surgeon and physician must work in harmony. Joint investigations are necessary. Therefore, the laboratory, postmortem examinations, the physician, the surgeon, must enter into the making of scientific surgery.

At a time when American surgery was relatively held in contempt, Senn, by a series of brilliant articles on practical subjects, such as pancreatic disease, branchial cysts, etc., made the surgeons of the world respect America. It is fitting, therefore, that the profession should acknowledge their indebtedness to this man, whose work has been an inspiration to ambitious Americans, and to know that by hard work a reputation can be built up in the West that is durable, and for this and many things more the profession owes a lasting debt to Senn. (Applause.)

Tribute from the Army.

Col. Philip F. Harvey, U. S. A., the next speaker, said that Dr. Senn has not only made substantial surgical contributions to the medical service of the army, but has extended many favors and rendered many kindnesses to the members of his corps.

Tribute from American Medical Association.

Dr. Lewis S. McMurtry, Louisville, Ky., said that Dr. Senn does not belong to the profession of Chicago; he belongs to no section, to no locality, but to the profession of the entire country. Besides, he is an American. (Applause.)

In the great advances that have been made in medicine and surgery during the past twenty years, surpassing in their extent and progress all that has been known in medical science in any century, the most potent influences in this great advancement have been the medical societies and medical press. They have played an important part in the stimulation of original research, in the development of individuality, and in the diffusion of knowledge. The local medical societies have grown both in size and number; they have become great postgraduate schools from which no pupil ever graduates.

There are medical societies which have varied functions. There are national associations for the development of special work, as the American Surgical Association, American Gynecological Society, etc. These societies are performing various important functions in the advancement of medical science in this country. They are limited in membership, and consist almost exclusively of authors, teachers and men who are known to be in the advanced rank as authorities in the various departments of medicine and surgery.

The American Medical Association has a function almost exclusively its own, almost unique, among the medical organizations in this country, namely, to reach the great body of the profession, to federate into one great organized body, through county, district and state societies, the organization of the profession which will be in accord with the spirit of the age, as seen in every department of human endeavor, and to diffuse knowledge among the members of the profession by the publication of a great weekly medical journal, and to bring the profession into close touch, so that great work can be accomplished. It has been the special purpose of this association to reach after the country doctors, the village practitioner, physicians in small towns, and bring them in close touch with one another. This association has, within the past few years, grown to be one of great power, and yet its work has scarcely begun. There are 130,000 physicians in the United States who need to be brought into the district and county societies and within the influence of this great national organization. In this work there have been leaders, among them the founder of the association—Dr. Nathan Smith Davis. Furthermore, through Dr. Senn's achievements, his influence has been felt in the association for years. His contributions to the Section on Surgery and Anatomy have been valuable. The association is the largest body of medical men in the world, and is destined to accomplish work along lines that will be more and more appreciated by the mass of the profession than any other medical society in existence. (Applause.)

The Medical Man Versus the Surgeon.

Dr. John A. Witherspoon, Nashville, Tenn., after captivating the audience by the stories he told in his droll way, said that if medical men had made diagnoses early enough surgeons would have saved thousands of patients they have lost. Since there is so much abdominal surgery being done, there is ample excuse for internists to make diagnoses as early as possible, because surgeons have so frightened the appendix that it curls up behind the cecum and internists can not find it. (Laughter.)

After brief reference to the late Spanish-American war, Dr. Witherspoon said that, should war threaten this country again, the boys of the fathers who wore the gray, and the boys of the fathers who wore the blue, will march side by side, and they will want no man as their surgeon more eagerly than Nicholas Senn. (Applause.) He is not only a great surgeon, but he has shown his patriotism. He is a good citizen. He is ever ready, on any and all occasions, to bare his face to the bayonet of any foe that may threaten this grand and glorious country. Therefore, the profession doubly owes him honor. (Applause.)

Dr. Senn as a Military Surgeon.

Dr. Charles Adams, Chicago, representing the Association of Military Surgeons, said that this organization has now many hundreds of members with one heart, and this beats for its founder, Dr. Nicholas Senn. He recounted Dr. Senn's contributions to military surgery and the active part he has taken in the deliberations of that body.

Dr. Senn as a Traveler.

Dr. Daniel R. Brower, Chicago, spoke of Dr. Senn as a traveling companion and of the trip he took with him around the world via Siberia. He referred to Dr. Senn's international reputation as a surgeon and to the manner in which he was royally and hospitably entertained by distinguished surgeons and physicians in the various cities they visited. Dr. Senn proved himself to be a very agreeable and delightful traveling companion, and their trip proved to be one triumphal march.

Dr. Senn in American Medical Literature.

Dr. Charles A. L. Reed, Cincinnati, said that Dr. Senn had contributed largely and liberally to the value and quality of the great mass of surgical literature. In the last twenty years his contributions to American medical literature amount to more than 250 entries, 238 of which relate to surgical subjects. In the list of titles are 12 printed volumes, some large, some small, but all of them important, many of them being used as text-books, others as standard works of reference in the majority of medical schools in the western hemisphere. Of these contributions a number have been translated into foreign languages. The range of subjects embraces practically every department of surgery. For the most part, these contributions are absolute protocols of original investigation. They cover, among other subjects, the surgery of the pancreas, stomach, the intestines, gall bladder, etc. Dr. Reed commended Dr. Senn's example in broad citizenship, a life actuated by an altruistic spirit of personal self-sacrifice, by a spirit of patriotism. (Applause.)

Dr. Senn as a Thorough Diagnostician.

Dr. William E. Quine, Chicago, spoke of his association with Dr. Senn as an interne at the Cook County Hospital. He has seen Dr. Senn as an interne engaged in controversy with the members of the attending staff of that institution—men who represented the strongest elements of the profession—in relation to problems of diagnosis, and he has seen him floor every one of them, though boy he was. The intensity of his earnestness, the thoroughness of detail in his methods, impressed Dr. Quine and inspired him in his work. It was something of a liberal education to be under the inspiration and guidance of such a man. He investigated thoroughly every case from the very foundation to the most minute and most intricate of its ramifications. Dr. Quine said that he was sure that Dr. Senn will close his professional career as he began it and as he has lived it through every day of his life—with sincerity, with intelligence, with dignity of effort, and with an eye single to the best interests, the greatest happiness of his fellow-men, and the greatest advancement of his brethren in the medical profession. (Applause.)

The singing of "Auld Lang Syne" brought the proceedings to a close.

CANADA.

Less Typhoid in Montreal.—During the whole of 1904 there were 574 cases of typhoid fever in Montreal. The disease has not been near so prevalent during 1905. In the first ten months of the year there were 294 cases, whereas in the same time in 1904 there were 493.

Clergyman Arrested for Practicing Medicine.—The Rev. W. J. Arnold, a well-known Anglican clergyman of Margaret's Bay, Nova Scotia, has been prosecuted by the medical board of Nova Scotia for practicing medicine without a license. The prosecution was not successful, as the minister did not collect any fees.

More Applicants for License.—Twenty-five candidates presented themselves before the examining board of the College of Physicians and Surgeons of British Columbia at the annual examinations held a few weeks ago. Eighteen were successful. The number of applicants for license was greatly in excess of any former year.

Hospital Additions.—A deputation waited on the Ontario government last week, asking aid to provide additional accommodation for the Gravenhurst and Toronto Free Consumption Hospitals. The former has room for 25 patients, the latter for 100.——The new Alexandra Hospital, Montreal, for contagious diseases among Protestants, will be ready for patients in January.——The Western Hospital, Toronto, is erecting a new addition at a cost of $10,000.——A sanitarium for consumptives in Quebec province is shortly to be erected. A company has been organized and has received 500 acres of land from the Quebec government.——Niagara Falls, Ont., is to have a hospital at a cost of $17,000.

Pharmacology

Resolutions on Patent Medicines.

The Wabash County Medical Society at a recent meeting adopted the following resolutions, which were sent us by Dr. G. C. Kingsbury:

WHEREAS: The traffic in patent medicines is attended with serious consequences to the individual, often imperiling and destroying life, and,

WHEREAS: The science of medicine is, by the use of such nostrums prevented from extending its beneficent work, and,

WHEREAS: The many publications of our country devote so much space to the advertising of such harmful mixtures containing so large a percentage of alcohol, and,

WHEREAS: You have undertaken a fearless, energetic and practical exposure and attack on this enemy to life and science, we, therefore,

Resolve: That the science of medicine owes you our sincere appreciation for so truthful a presentation of the evils, deceptions, and the facts regarding this baneful industry to the public, and advertisers of these nostrums, and,

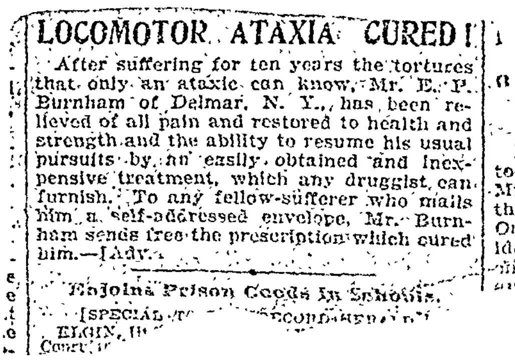
Resolve: That the medical journals should assist in destroying this traffic which is so inimical to the progress of medical science, and lives of the people, and

Resolve: That this society send these resolutions to THE JOURNAL of the American Medical Association, and the *Illinois State Medical Journal.*

BIOPLASM.

A Concrete Instance of the Manner in Which Remedies Supposed to be Ethical Are Exploited to the Laity.

The accompanying advertisement has been appearing in the newspapers for some time, and its resemblance to the old advertisement of the "Rev. Joseph T. Inman" of lost-manhood fame, aroused the curiosity of a member of THE JOURNAL force—or it may have been an innate desire to keep in touch with things. In any event, he, as a layman, answered the advertisement, and, in due time, an imitation typewritten letter was received. In it was rehearsed the old, old story of how the writer had for years suffered the tortures, etc., how he had tried all kinds of physicians, all kinds of patent medicines, serums, various climates, etc., until he heard of the virtues of the medicines which finally cured him. Accompanying the circular letter was a sheet containing the prescription, with full directions. But it was not the "Rev. Joseph T. Inman" trick in all its apparent simplicity; it was Inman improved. Here is the first prescription: "Bioplasm (Bower) series No. 235a, No. 212, in sealed bottles; 2½ oz., containing about 175 tablets, costs $1.50." Then followed the directions. Farther down the sheet is the second preparation, which is: "Sal Lithin. Take a heaping teaspoonful," etc. Bioplasm! Sal Lithin!! Certainly we have seen these names before. "These prescriptions may be had of almost any druggist. If not, send to the manufacturers, Bioplasm Company, 100 William Street, New York."



LOCOMOTOR ATAXIA CURED!

After suffering for ten years the tortures that only an ataxic can know, Mr. E. P. Burnham of Delmar, N. Y., has been relieved of all pain and restored to health and strength and the ability to resume his usual pursuits by an easily obtained and inexpensive treatment, which any druggist can furnish. To any fellow-sufferer who mails him a self-addressed envelope, Mr. Burnham sends free the prescription which cured him.—[Adv.

Enjoins Prison Goods In Schools.

Of course! We pick up certain medical journals and find that "Bioplasm" and "Sal Lithin" are "ethical proprietary" preparations, put up for physicians' use, for are they not advertised in medical journals? We wondered whether or not the Bioplasm Company was aware of the generous work that E. P. Burnham is doing, but this wonder only lasted ten days, for then came a letter from the company itself, with circulars, testimonials and other literature, all appealing directly to the credulous laymen, and especially to those suffering from that terrible affliction, locomotor ataxia. Of course, the literature said that bioplasm is endorsed by physicians, and, in fact, testimonials from medical men were among the literature sent to this layman by the company.

We shall have something more to say about this wonderful cure-all, bioplasm, in the immediate future.

The Great American Fraud, Liquozone.

SAMUEL HOPKINS ADAMS.

Twenty years ago the microbe was making a great stir in the land. The public mind, ever prone to exaggerate the importance and extent of any new scientific discovery, ascribed all known diseases to microbes. The infinitesimal creature with the mysterious and unpleasant attributes became the leading topic of the time. Shrewdly appreciating this golden opportunity, a quack genius named Radam invented a drug to slay the new enemy of mankind, and gave it his name. "Radam's Microbe Killer" filled the public prints with blazonry of its lethal virtues. As it consisted of a mixture of muriatic and sulphuric acids with red wine, any microbe which took it was like to fare hard; but the ingenious Mr. Radam's method of administering it to its intended prey, via the human stomach, failed to commend itself to science, though enormously successful in a financial sense through flamboyant advertising. . . .

In time some predaceous bacillus, having eluded the "killer," carried off its inventor. His nostrum soon languished. To-day it is little heard of, but from the ashes of its glories has risen a mightier successor, "Liquozone." Where twenty years ago the microbe reveled in publicity, to-day we talk of germs and bacteria; consequently Liquozone exploits itself as a germicide and bactericide. It dispenses with the red wine of the Radam concoction, and relies on a weak solution of sulphuric and sulphurous acids, with an occasional trace of hydrochloric or hydrobromic acid. . . . Yet the Liquozone Company is not a patent medicine concern. We have their own word for it.

"We wish to state at the start that we are not patent medicine men, and their methods will not be employed by us. . . . Liquozone is too important a product for quackery."

The head and center of this non-patent-medicine cure-all is Douglas Smith. Mr. Smith is by profession a promoter. He is credited with a keen vision for profits. Several years ago he ran on a worthy ex-piano dealer, a Canadian by the name of Powley (we shall meet him again, trailing clouds of glory in a splendid metamorphosis), who was selling with some success a mixture known as "Powley's Liquefied Ozone." This was guaranteed to kill any disease germ known to science. Mr. Smith examined into the possibilities of the product, bought out Powley, moved the business to Chicago, and organized it as the Liquid Ozone Company. Liquid air was then much in the public prints. Mr. Smith, with the intuition of genius, and something more than genius' contempt for limitations, proceeded to catch the public eye with this frank assertion: "Liquozone is liquid oxygen—that is all."

The object of the company was not to make money, but to succor the sick and suffering. They say so themselves in their advertising. For some reason, however, the business did not prosper as its new owner had expected. A wider appeal to the sick and suffering was needed. Claude C. Hopkins, formerly advertising manager for Dr. Shoop's Restorative (also a cure-all) and perhaps the ablest exponent of his specialty in the country, was brought into the concern, and a record-breaking campaign was planned. This cost no little money, but the event proved it a good investment. President Smith's next move showed him to be the master of a silver tongue, for he persuaded the members of a very prominent law firm who were acting as the company's attorneys to take stock in the concern, and two of them to become directors. These gentlemen represent, in Chicago, something more than the high professional standing of their firm; they are prominent socially and forward in civic activities; in short, just the sort of people needed by President Smith to bulwark his dubious enterprise with assured respectability.

In the Equitable scandal there has been plenty of evidence to show that directors often lend their names to enterprises of which they know practically nothing. This seems to have been the case with the lawyers. One point they brought up: was liquozone harmful? Positively not, Douglas Smith assured them. On the contrary, it was the greatest boon to the sick in the world's history, and he produced an impressive bulk of testimonials. This apparently satisfied them; they did not investigate the testimonials, but accepted them at their face value. They did not look into the advertising methods of the company; as nearly as I can find out, they never saw an advertisement of liquozone in the papers until long afterward. They just became stockholders and directors, that is all. They did as hundreds of other upright and well-meaning men had done, *in lending themselves to a business of which they knew practically nothing.*

While the lawyers continued to practice law, Messrs. Smith and Hopkins were running the Liquozone Company. An enormous advertising campaign was begun. Pamphlets were issued containing testimonials and claiming the soundest of professional backing. Indeed, this matter of expert testimony, *chemical, medical,* and bacteriologic, is a specialty of liquozone. To-day, despite its reforms, it is supported by an ingenious system of pseudo-scientific charlatanry. In justice to Mr. Hopkins, it is but fair to say that he is not responsible for the basic fraud; that the general scheme was devised, and most of the bogus or distorted medical letters arranged, before his advent. But when I came to investigate the product a few months ago, I found that the principal defense against attacks consisted of scientific statements which would not bear analysis, and medical letters not worth the paper they were written on. In the first place, the liquozone people have letters from chemists asseverating that the compound is chemically scientific. . .

[Mr. Adams goes on to say that, on investigation, he found that the technical indorsement obtained by this company, when analyzed, failed to bear out the claims of liquozone as a medicine. Inquiries conducted along medical lines revealed the fact that the published indorsements were either misstatements or a garbled version of what really had been written about liquozone. One physician, a hospital interne, who was paid to make bacteriologic tests of the germicidal power of liquozone, stated that it had shown such powers, but that the product was worthless medicinally. The last half of his report was suppressed; only the first half was printed under the designation of "Report made by the ——— Hospital." Another statement was said to have been published by a Dr. "W. H. Myers" in "The New York Journal of Health." Dr. Myers and that journal, Mr. Adams says, are purely fictitious. Another testimonial purporting to come from a physician was found to have been written by a veterinary surgeon. The Suffolk Hospital and Dispensary in Boston, through its president, Mr. Smith, testified in glowing terms to the remedial value of liquozone, but the hospital medical authorities know nothing of liquozone and never prescribed it. One testimonial was found to be genuine, having been written by a "cancer-cure" specialist, who stated that the letter was "not solicitated." Letters addressed by Mr. Adams to various institutions in Chicago elicited the information that it either had never been used or that it had been experimented with for external application or that a few private patients had purchased it, but on no recommendation from the physicians. Attempts made personally to peruse the "overwhelming number of medical indorsements" failed, the officials of the company claiming that these indorsements were "in the press" and could not be shown.]

. . . In a pamphlet issued by the company and since withdrawn occurs this sprightly sketch:

"Liquozone is the discovery of Professor Pauli, the great German chemist, who worked for twenty years to learn how to liquefy oxygen. When Pauli first mentioned his purpose men laughed at him. The idea of liquefying a gas—of circulating liquid oxygen in the blood—seemed impossible. But Pauli was one of those men who set their whole hearts on a problem and followed it out either to success or the grave. So Pauli followed out this problem, though it took twenty years. He clung to it through discouragements which would have led any lesser man to abandon it. He worked on it despite poverty and ridicule," etc.

Alas for romance! The scathing blight of the legal mind descended on this touching story. The lawyer-directors would have none of "Professor Pauli, the great German chemist," and liquozone destroyed him, as it had created him. Not totally destroyed, however, for from those rainbow wrappings, now dissipated, emerges the humble but genuine figure of our old acquaintance, Mr. Powley, the ex-piano man of Toronto. *He is the prototype of the Teutonic savant.* So much the liquozone people now admit, with the defence that the change of Powley to Pauli was, at most, a harmless flight of fancy, *"so long as we were not attempting to use a name famous in medicine or bacteriology in order to add prestige to the product." A plea which commends itself by its ingeniousness at least.* . . . *Just as to* peruna all ills are catarrh, so to liquozone every disease is a germ disease. Every statement in the new prospectus of cure "has been submitted to competent authorities, and is *exactly* true and correct," declares the recently issued pamphlet, "Liquozone, the Tonic Germicide"; and the pamphlet goes on to ascribe, among other ills, asthma, gout, neuralgia, dyspepsia, goiter, and "most forms of kidney, liver, and heart troubles" to germs. I don't know just which of the eminent authorities who have been working for the Liquozone Company fathers this remarkable and epoch-making discovery. It might be Professor Pauli, or perhaps the sulphuric-acid-proof firm of Dickman & Mackenzie. Whoever it is ought to make the definite facts public, in the interests of humanity as well as their own. Monuments of discarded pill boxes will celebrate the liquozone savant who has determined that dyspepsia is a germ trouble. The discovery that gout is caused by the bite of a bacillus and not by uric acid is almost as important an addition to the sum of human knowlege as the determination of a definite organism that produces the twinges of neuralgia, while the germ of heart disease will be acclaimed with whoops of welcome from the entire medical profession. The old claim is repeated that nothing enters into the production of liquozone but gases, water, and a little harmless coloring matter, and that the process requires large apparatus and from eight to fourteen days' time. I have seen the apparatus, consisting of huge wooden vats, and can testify to their impressive size. And I have the assurance of several gentlemen whose word (except in print) I am willing to take, that fourteen days' time is employed in impregnating every output of liquid with the gas. The result, so far as can be determined chemically or medicinally, is precisely the same as could be achieved in fourteen seconds by mixing the acids with the water. The product is still sulphurous and sulphuric acid heavily diluted, that is all. . . .

[Mr. Adams further states that of the chemists and bacteriologists employed by the Liquozone Company there is not one who will risk his professional reputation on the simple and essential statement that liquozone taken internally kills germs in the human system. Under the direction of Mr. Adams, and in the presence of Dr. Gradwohl, representing the Liquozone Company, a series of guinea-pig tests was made by the Lederle Laboratories. The result was that liquozone was found to have absolutely no curative effect, but did, when given in pure form, lower the resistance of the animals which had been inoculated with anthrax, diphtheria and tuberculosis, so that they died a little earlier than those not treated. Dr. Gradwohl was satisfied of the fairness of the tests and declared that, in his opinion, the tests had proved the total ineffectiveness of liquozone as an internal germicide. Mr. Adams says that these experiments showed further that liquozone may decrease the chances of the patient's recovery with every dose that is swallowed, but certainly would not increase them. Mr. Adams continues as follows:]

Since the announcement of this article, and before, *Collier's* has been in receipt of much virtuous indignation from a manufacturer of remedies which, he claims, liquozone copies. Charles Marchand has been the most active enemy of the Douglas Smith product. He has attacked the makers in print, organized a society, and established a publication mainly devoted to their destruction, and circulated far and wide injurious literature (most of it true) about their product. Of the relative merits of "Hydrozone," "Glycozone" (Marchand's products), and "Liquozone," I know nothing; but I know that the Liquozone Company has never in its history put forth so shameful an advertisement as the one reproduced on this page [which appeared in The Journal, Sept. 23, 1905, p. 936], signed by Marchand, and printed in the New Orleans *States* when the yellow-fever scare was at its height.

And Hydrozone is an "ethical" remedy; its advertisements are to be found in reputable medical journals.—Excerpts from *Collier's Weekly,* Nov. 18, 1905.

MEMBERSHIP OF THE PROPRIETARY ASSOCIATION OF AMERICA

COPIED FROM THE TWENTY-THIRD ANNUAL REPORT

The following is a list of the members of the Proprietary Association of America, taken from the "Twenty-Third Annual Report" of that body:

- ALLCOCK MANUFACTURING CO., NEW YORK.
  - Allcock's Porous Plasters.
  - Brandreth's Pills.
  - Allcock's Corn and Bunion Shields.
- ALTA PHARMACAL CO., ST. LOUIS.
  - Melachol.
  - Phaselin.

Marriages

Elmer E. Evans, M.D., to Miss Hazel V. Camp, both of East Oakland, Cal., October 24.

Francis Welsh, M.D., Hospital, Ill., to Miss Lena Ackerman of Yorkville, Ill., recently.

Thomas Elliot Buck, M.D., to Miss Lulu T. Tillewein, both of St. Louis, November 1.

Thomas D. Palmer, M.D., Canon City, Colo., to Mrs. Emma Baily Sherrill, November 8.

T. Edward Bailly, M.D., to Miss Stella Fortmann, both of San Francisco, November 15.

Thomas E. Hoxsey, M.D., to Miss Leila Posey, both of Spokane, Wash., November 7.

Edward Barr, M.D., Rome, Ky., to Miss Annie Ellis of Masonville, Ky., November 2.

Charles Reneau Andrews, M.D., to Miss May Waldo, both of Atlanta, Ga., November 8.

James House Bute, M.D., to Miss Claire Robinson, both of Houston, Texas, November 8.

Paul Lange Cort, M.D., to Miss Mary Reeder Scudder, both of Trenton, N. J., November 16.

J. H. Aleshire, M.D., to Mrs. Addie Miller, both of Plainville, Ill., at Palmyra, October 31.

Russell J. Shull, M.D., Hugo, I. T., to Miss Virginia Claggett of Marlboro, Va., November 1.

Homer Thrall Joy, M.D., to Miss Elizabeth Van Buren, both of New York City, November 9.

Thomas P. West, M.D., Bedford City, Va., to Miss Sallie C. Ford of Lynchburg, Va., November 1.

Loamin J. Smith, M.D., Ridge Springs, S. C., to Miss Lucile Provence of Tuskegee, Ala., October 31.

George Winslop Lawton, M.D., to Miss Susie Schmieding of the City of Mexico, November 11.

Thomas Meares Green, M.D., to Miss Emma Perrin West, both of Wilmington, N. C., November 16.

Clarence Maxfield Frye, M.D., Rock Falls, Ill., to Miss Birdie Ferris, of Sterling, Ill., November 7.

C. Bernard Voigt, M.D., Mattoon, Ill., to Miss Pearl Warner of Shelbyville, Ill., at Chicago, November 6.

Henry Walter Gibbons, M.D., San Francisco, to Miss Hazel Noonan of Los Angeles, Cal., November 15.

Burnley Lankford, M.D., Norfolk, Va., to Miss Henrietta E. Grant, at Charlottesville, Va., November 8.

William H. Morgan, M.D., Keatchie, La., to Miss Lilliore C. Decker of Spottsylvania County, Va., November 8.

Walter Philip Eidmann, M.D., to Miss Cora E. Jackson, both of St. Louis, Mo., at Belleville, Ill., November 8.

Samuel Evans Watkins, M.D., to Miss Mary Leontine Campbell, both of Washington, D. C., November 2.

Samuel Peachy Latané, M.D., to Miss Elizabeth Faulkner Shaw of Marco, Fla., at Valdosta, Ga., November 2.

William K. Newton, M.D., Paterson, N. J., to Miss Cornelia Ridgely Hunt of Washington, D. C., November 15.

Herbert Lee Kneisley, M.D., Westminster, Md., to Miss Daisy Sophia Bester, at Hagerstown, Md., November 9.

John Charles Macgill, M.D., Catonsville, Md., to Miss Annie Campbell Gordon Thomas, at Baltimore, November 8.

Deaths

George Benson Dunmire, M.D. Jefferson Medical College, Philadelphia, 1865, a member of the American Medical Association, the Medical Society of the State of Pennsylvania and once its treasurer, Philadelphia County Medical Society, Pathological Society of Philadelphia and Obstetrical Society of Philadelphia; hospital steward of the One Hundred and Twenty-fifth *Pennsylvania Volunteer Infantry in the Civil* War, died at his home in Philadelphia, October 31.

George W. Hudspeth, M.D. St. Louis Medical College, 1878, a prominent physician of Little Rock, Ark., a member of the American Medical Association, American Public Health Association, Arkansas Medical Society, and Pulaski County Medical Society; ex-member of the Arkansas State Board of Health, died at St. Joseph's Hospital, Memphis, Tenn., October 29, after a prolonged illness from septicemia following an operation on the kidney, aged 54.

Samuel E. Bibby, M.D. Howard University Medical Department, Washington, D. C., 1883, colonel and surgeon general of Idaho, a member of the American Medical Association and of the Association of Military Surgeons of the United States; for several years physician at the Lapwai Indian reservation; regimental surgeon in the Idaho National Guard through the Coeur d'Alene riots, died at his home in Grangeville, Idaho, November 3, aged 52.

Alexander Powe Hall, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1859, of Mobile, Ala., surgeon in the Confederate service throughout the Civil War; and one of the volunteer physicians who served through the yellow fever epidemic in Memphis, Tenn., in 1878, died at the Providence Infirmary, Mobile, October 22, from injuries received in a street car accident the day before, aged 69.

William Henry Borden, M.D. University of Buffalo Medical Department, 1849, a member of the American Medical Association, the oldest member of the Wisconsin Medical Society; surgeon of the First Wisconsin Volunteer Heavy Artillery in *the Civil War;* for many years a member of the board of visitors of the State University, died at his home in Milton, Wis., from senile debility, October 30, aged 81.

***Cornelius N. Lyman,* M.D.** Transylvania University Medical Department, Lexington, Ky., 1843, a member of the American Medical Association; from 1883 to 1887 a member of the General Assembly of Ohio, and especially identified with the interests of the various benevolent institutions of the state, died at his home in Wadsworth, Ohio, October 24, aged 86.

Frederick Templeton Zabriskie, M.D. College of Physicians and Surgeons in the City of New York, 1895, formerly of Phoenix, Ariz., but for two years a practitioner of Pittsfield, Mass.; a member of the Berkshire District Medical Society, and a young surgeon of great promise, died at his father's home in New York City, from pneumonia, November 4, after an illness of two weeks, aged 34.

Elias L. Bissell, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1861, surgeon of the Twenty-second and afterward of the Forty-fourth New York Volunteer Infantry in the Civil War, died at his home in Buffalo, N. Y., November 1, from heart disease, aged 72.

Alfred N. Marion, M.D. McGill University Medical Department, Montreal, 1864, surgeon in the army during the Civil War, agent at the Tulalip Indian Reservation, Wash., in 1887, and thereafter clerk of the United States Court in Walla Walla and a practitioner in Seattle, died suddenly at his home in Seattle, October 20, from nephritis, aged 65.

Hal Walker Manson, M.D. University of Nashville and Vanderbilt University medical departments, Nashville, Tenn., 1867, a Confederate veteran, in 1897 a member of the Texas legislature, died at his home in Rockwall, Texas, October 27, after an illness of several weeks, aged 64.

Helen Frances Warner, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872, a graduate of Vassar College in 1867, one of the pioneer women physicians of Detroit, died at her home in that city October 23, after an illness of six years, aged 62.

J. B. Bouchard, M.D. University of the Victoria College, Coburg, Ont., 1877, for twenty-five years physician to the east division of the Montreal police force, died at his home in that city November 6, from disease of the throat, after an illness of two years, aged 49.

George W. Kemp, M.D. Charity Hospital Medical College, Cleveland, Ohio, 1863, assistant surgeon of the One Hundred and Thirteenth Ohio Volunteer Infantry in the Civil War, died at his home in Marseilles, Ohio, October 24, after a long illness, aged 83.

Lafayette Charles Loomis, M.D. University of Georgetown Medical Department, Washington, D. C., 1863, of Winthrop Heights, Washington, D. C., one of the founders of Adelphian Academy, Brockton, Mass., died at Frederick, Md., October 17, aged 81.

Clarence B. McClure, M.D. Kentucky School of Medicine, Louisvile, 1871, formerly assistant physician at the Central Indiana Hospital for the Insane, Indianapolis, died at his home in Jeffersonville, Ind., October 28, from disease of the liver, aged 57.

Anthyme S. Menard, M.D. University of Vermont Medical Department, Burlington, 1888, whose injury October 19 by a runaway horse was noted in The Journal of October 28, died from his injuries October 20, at his home in Holyoke, Mass.

James Herbert Austin, M.D. Toronto University, 1893, formerly of Kansas City, Mo., and El Paso, Texas, died at his home in Toronto, November 5, from tuberculosis, after an illness of six years, aged 34.

Morris B. Gerberich, M.D. Pennsylvania, 1887, president of the Lebanon (Pa.) common council, died at his home in Lebanon, Pa., after a short illness, from intussusception of the bowel, November 1, aged 44.

Charles G. McKinley, M.D. Starling Medical College, Columbus, Ohio, 1852, for many years a practitioner of Olathe, Kan., died at his home in Kansas City, Mo., October 24 from senile debility, aged 84.

Edward E. French, M.D. Pennsylvania, 1887, of Trenton, N. J., died in St. Francis' Hospital, Trenton, October 20, from nephritis, after an illness of four years, aged 49.

Carlos Wilcox, M.D. Des Moines, 1887, died at his home in Huron, S. D., October 2, from cerebral hemorrhage, after a long illness, aged 67.

John Frank Lane, M.D. St. Louis, 1889, of Linn, Mo., was drowned while attempting to ford a flooded creek near his home, October 24.

Joseph P. Gregory, M.D. University of Louisville Medical Department, 1873, died suddenly at his home in Gainesville, Ark., October 16.

Penfield B. Goodsell, M.D. Vermont Medical College, Woodstock, 1852, died at his home in Roxbury, Boston, October 24, aged 70.

Charles T. Weatherly, M.D. Atlanta (Ga.) Medical College, 1874, died at his home in Benton, Ala., October 23, aged 53.

Miscellany

THE DEMAND OF THE SOUTH FOR FEDERAL CONTROL OF QUARANTINE.

The following excerpts are from editorials that have recently appeared in newspapers of the southern states. To these are added quotations from a few northern papers. We comment editorially on the subject on page 1576.

Alabama.

"With a rational but thorough national quarantine law, with the government health department in full control, we might expect fairness and intelligence in carrying out and enforcing its provision. . . . The ability of the federal government to handle such matters is universally recognized, and the ability of local governments to combat the foe is suspected if not entirely scouted. . . . After all objections have been proposed and considered there remains the plain fact that the health and lives of millions of people should be among the first consideration of a government of and for all the people. If that can only be assured by a national law—and that appears evident—then there should be no more objection to such law."—*Birmingham Advertiser.*

"The hope is that the marine-hospital doctors can wholly eliminate the disease in New Orleans before frosts fall. If they can do that public sentiment will demand that interstate and international quarantine be placed in the hands of the federal government, thus doing away with the rivalry between states, with all commercialism, in a matter pertaining to health and life. The public health outranks trade at every step. The *Atlanta Journal* joins the increasing ranks of those who demand federal control of quarantine. Public sentiment is rapidly crystallizing in all the cotton states in a demand for federal control of quarantine."—*Birmingham Age-Herald.*

Florida.

"Pensacola asks that all seaport towns join her in this request, and also the request that congress pass a general quarantine law, and we see no objection whatever to such action if the nation is more successful and resourceful in its methods of operating such law than the states are."—*Pensacola News.*

"But precautions against the transmission of disease through the ordinary means of transportation, where they are necessary at all, must be subject to some general regulation, such as the federal officers alone can exercise."—Jacksonville *Times-Union,* from Philadelphia *Public Ledger.*

Georgia.

"One result of the yellow fever epidemic in Louisiana has been to convert many doubters and scoffers to a firm belief in a national quarantine system and government control in case of epidemic."—Savannah *Press.*

Louisiana.

"It is recognized that the desired uniformity of quarantine, that will be equally strong in all its parts, can be secured only through the federal government."—New Orleans *Democrat.*

"The ruinous and barbarous quarantines established by small communities against the world, the stoppage of United States mails and interstate traffic has resulted in a demand by the press of the country for a scientific and uniform quarantine service such as can be exercised and maintained only by the national health organization."—New Orleans *States.*

"The *Times* rejoices to know that the Louisiana Press Association, through its president, Charles E. Schwing, of Plaquemine, has begun an agitation looking to federal control of the quarantine regulations throughout the country. This paper, at the very beginning of the present yellow-fever epidemic, pointed out the senselessness of some of the quarantines established by various communities, and advocated placing this power of quarantine in the hands of the national government. In a subsequent article, the *Times* sought to emphasize the importance of uniform regulations among the states, pointing out that this could not be hoped for unless needed authority is vested in a supreme, independent and impartial department, such as the Public Health and Marine-Hospital Service of the United States."—Shreveport *Times.*

Missouri.

"Adequate and uniform precautions can not be taken unless under the direction of some central authority. This means that the whole scheme of quarantine at the great ports of the country should be under charge of the national authorities. . . . National quarantine is what the country wants for all its ports, and the coming Chattanooga conference ought to start a movement which will secure congressional legislation along that line."—St. Louis *Globe-Democrat.*

"Governor Blanchard expresses himself as being in favor of federal control of maritime quarantines and is also inclined toward such control of interstate quarantines."—From an interview with Governor Blanchard of Louisiana.

Mississippi.

"For the protection of the coast—seaports—I am in favor of vesting absolute authority in the federal government."—From an interview with Governor Vardaman.

Tennessee.

"As a matter of economy, then, as well as policy, desirability and safety, as explained yesterday, the entire South should take up this federal marine quarantine at once and use its best endeavors to induce the government to establish it at the earliest possible moment."—Memphis *Commercial-Appeal.*

"The board of health of Pensacola, Fla., has adopted strong resolutions favoring national control of quarantine regulations at all southern seaports and urges the Florida congressional delegation to urge the same. The sentiment expressed by the people of Pensacola has become very general in the south since this last outbreak of fever at New Orleans, and there are strong reasons for believing that the opposition hitherto manifested by southern representatives will be withdrawn and the principle of national control of quarantine established. The press of the south is very nearly unanimous for the proposition."—Chattanooga *Times.*

"There is a growing sentiment in the South, and all over the country as for that, for a federal quarantine law. The *News*, like a great many other newspapers in the South, has not jumped into this popular wave and demanded that a law be passed at the next session of congress establishing federal quarantine, but under sensible regulations we believe that such a plan would be best for the whole country."—Chattanooga *News.*

"In view of these facts, it is declared to be the sense of the Pensacola board of health 'that the quarantine of all seaport towns should be under the charge and control of the general government.' The *American* unqualifiedly indorses the conclusion of the Pensacolans. It has long been the opinion of this newspaper that the general government is the only power capable of handling quarantine matters in such emergencies."—Nashville *American.*

Texas.

"Indeed, now that the importance of a strict quarantine is appreciated, and to avoid those embarrassments which proceed from conflicts of state laws and quarantine, the whole matter of public health, as far as contagious or infectious diseases are concerned, may be turned over to the federal government, with the consent of the states."—Galveston *News* and Dallas *News.*

Northern Opinions.

"Sentiment in favor of a national quarantine service appears to be practically unanimous among those who are able to take an unprejudiced view of the matter. The Philadelphia *Press* remarks that the more rapid, the more complete and the more sweeping the change from the patchwork state quarantines wrangling on the Gulf to federal authority the better. State quarantine has lasted its day. It is an expensive and useless nuisance. It is no more needed than state harbor lights, a state immigrant service or any other regulation of foreign or interstate commerce. The day for shotgun quarantine has passed in this country. The New York *Evening Post* thinks that a national quarantine service is brought distinctly nearer by the appeal of Louisiana to the federal government and suggests that congress will undoubtedly be called on to make the powers and the duties of the national government larger and more precise in all that relates to oversight of the public health. These views are in entire accord with what was said by the *Bee* some days ago. . . . The demand that is being made for a national quarantine service should not be allowed to die out with the subsidence of the yellow fever, but should be pressed on congress until there is legislation giving the national government absolute control over quarantine. Existing law does not go far enough."—Omaha (Neb.) *Bee.*

"The question of physical health is put first, and it is very important. An outbreak of yellow fever in the south, with no common purpose or provision to meet it, throws the people into a panic that produces scenes and acts of almost indescribable inhumanity. Shotgun quarantines are a disgrace to civilization, and the only remedy—if there is a remedy—is in concert of action and standing means to meet such emergencies. The national power should be invoked."—Washington (D. C.) *Star.*

"In no section of the United States is the principle of home rule as formulated in the doctrine of state rights so firmly established as in the South. Southern communities are tenacious of their local police powers. This being so, some surprise may be felt at the unanimity of the sentiment now prevalent throughout the portion of the South which has experienced or feared the yellow fever in epidemic form in favor of the surrender of their quarantine system to the federal government and of turning over the campaign against the mosquito to the Marine-Hospital Service."—New York *Times.*

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

STATUS OF GASTRECTOMY.

North Platte, Neb., Nov. 8, 1905.

To the Editor:—I would like to know through The Journal the present status of the operation of removing the whole stomach and whether the operation has ever been performed with satisfactory results. D. T. Quigley.

Answer.—The entire stomach has now been removed several times for carcinoma and patients have lived for from several months to two years, usually dying from metastatic carcinoma. Cases suitable for total removal of the stomach are, of course, rare. So far as the functional results are concerned after complete removal of the stomach, they have been satisfactory.

POSTGRADUATE COURSE IN BERLIN.

Worthington, Minn., Nov. 9, 1905.

To the Editor:—In The Journal, November 4, you gave a brief review of a post-graduate course to be given in Berlin next spring at the time of the dedication of the "Empress Friedrich House." Can you give me the time when these lectures will take place and the address of some one with whom I can correspond for further information? Henry Wiedow.

Answer.—The cycle of lectures is to be given during March and April, 1906. Professor R. Kutner is general secretary of the postgraduate movement (Zentralkomitee für das ärztliche Fortbildungswesen). His address is Elssholzstrasse 13, Berlin W. 30. He is editor of the journal issued by the central committee. His report for the five years since the committee was organized was recently published by J. S. Preuss, Berlin, in a book of 114 pages, giving the details and work accomplished by the postgraduate movement in Prussia.

METHYLENE BLUE TEST FOR TYPHOID URINE.

Parkersburg, W. Va., Oct. 28, 1905.

To the Editor: A friend of mine has called my attention to a new test of the urine, methylene blue, in typhoid fever. Will you give some information about it, where we can find literature concerning it, etc.? W. H. Sharp.

Answer.—The test is sometimes called Russo's test. The original paper is found in *Riforma Medica,* vol. xxi, No. 19, 1905. A partial abstract of the paper appears in The Journal, vol. xlv, 1905, p. 363. The technic of the test is very simple and is as follows: Four drops of a 1 to 1,000 aqueous solution of methylene blue are added to 4 or 5 c.c. of suspected urine. If the reaction is positive the mixture turns to an emerald or mint green hue. A light green or bluish green tint shows a negative reaction. The positive reaction is not affected by boiling the urine or the previous ingestion of such compounds as phenacetin, salol, quinin, calomel, etc. It is given as early as the second day of the disease and persists throughout its course. The mint green hue is first noted and the emerald green hue appears as the disease progresses. If the course is favorable the tone becomes more and more bluish, while if unfavorable the emerald tint persists. The chief point in favor of the test is its simplicity. It is also quite as reliable as the diazo reaction of Ehrlich. It is, however, given in cases of measles, smallpox, chronic and suppurative tuberculosis. It is not given in varioloid, varicella, scarlet fever, miliary tuberculosis, appendicitis and other conditions. The difficulty in the application of the test comes in the ability to recognize the various tints of green which may be present. With a little practice, however, the positive reaction may be readily detected. The fact that the test is not given in a miliary tuberculosis, appendicitis, varicella, etc., makes it invaluable as an aid in differential diagnosis.

State Boards of Registration

COMING EXAMINATIONS.

Board of Registration in Medicine in Massachusetts, State House, Boston, November 4-15. Secretary, E. B. Harvey, Boston.

Connecticut Medical Examining Board, City Hall, New Haven, November 14-15. Secretary, Charles A. Tuttle, New Haven.

State Board of Health of Louisiana, New Orleans, November 14-15. Secretary, F. A. Larue, New Orleans.

State Board of Health of West Virginia, Clarksburg, November 14-16. Secretary, H. A. Barbee, Pt. Pleasant.

Wyoming Board of Medical Examiners, Cheyenne, December 6. Secretary, S. B. Miller, Laramie.

Examining Board representing the President and Fellows of the Medical Society of Delaware at Dover, and the Homeopathic Board, Wilmington, December 12. Secretary, P. W. Tomlinson, Wilmington.

Ohio State Board of Medical Registration and Examination, Columbus, December 12-14. Secretary, F. Winders, Columbus.

Medical Examining Board of Virginia, Richmond, December 12-15. Secretary, R. S. Martin, Stuart.

State Board of Health of Missouri, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

Board of Medical Examiners State of California, San Francisco, December 20. Secretary, Charles L. Tisdale, San Francisco.

Board of Medical Examiners of Maryland, Baltimore, December 13-16. Secretary, J. McScott, Hagerstown.

Montana October Report.—Dr. W. C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, Oct. 3-5, 1905. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 24, of whom 16 passed and 8 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Syracuse University	(1902)	80
Kentucky School of Medicine	(1902)	77.7
University of Tennessee	(1901)	75.1

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending November 11:

Hess, Louis T., asst.-surgeon, ordered to Fort Lawton, Wash., for duty.

Collins, C. C., asst.-surgeon, ordered to Fort Walla Walla, Wash.

Pyles, Will L., asst.-surgeon, ordered to Jefferson Barracks, Mo., for duty.

Rafferty, Ogden, surg., granted two months' leave of absence.

Reynolds, Chas. R., asst.-surgeon, assigned to duty as surgeon on transport *Logan*, next voyage to Manila, where, on arrival, he will report to commanding general, Philippines Division, for assignment to duty.

Wadhams, S. H., asst.-surg., granted 30 days' leave of absence, with permission to apply for 30 days' extension.

Adair, Geo. W., asst.-surgeon general, granted 15 days' leave of absence.

DeWitt, Wallace, asst.-surgeon, granted 30 days' leave of absence.

Frick, Euclid B., surgeon, ordered to assume temporary charge of chief surgeon's office, Department of Dakota, during the absence of Col. Adair, on leave of absence.

Edwards, Jas. F., asst.-surgeon, granted leave of absence from November 17th to and including December 31, 1905. His resignation as an officer of the army has been accepted by the President, to take effect December 31.

Purnell, Julius M., contract surgeon, ordered to Alcatraz Island, Cal., for temporary duty.

Barney, Fred M., contract surgeon, arrived at Fisherman's Point, Cuba, for duty.

Daywalt, George W., contract surgeon, left Fort St. Philip, La., on sick leave for seven days.

Waddell, Ralph W., dental surgeon, arrived at Fort Crook, Neb., for duty.

Boak, S. Davis, dental surgeon, left Fort Washington, Md., on leave of absence.

Carpenter, Alden, dental surgeon, arrived at Boise Barracks, Idaho, for duty.

Ames, Roger P., contract surgeon, arrived at Fort Saint Philip, La., for duty.

Jones, George H., contract surgeon, returned to duty at Fort Fremont, S. C., from leave of absence.

Byars, Caspar R., contract surgeon, returned to Fort Sam Houston, Texas, from duty at Fort Sill, Okla.

Dickenson, Clarence F., contract surgeon, left Fort Logan, Colo., and arrived at Fort Douglas, Utah, to accompany 22d Battery, Field Artillery, on overland march to Fort Riley, Kans.

Slater, Ernest F., contract surgeon, arrived at Washington Barracks, D. C., for temporary duty.

Adair, George F., contract surgeon, left Fort Wadsworth, N. Y., on leave of absence for fifteen days.

Navy Changes.

Changes in the Medical Corps U. S. Navy, for the week ending November 11:

Riggs, C. E., surgeon, detached from the *Dolphin* and ordered home to wait orders.

Spratling, L. W., surgeon, detached from the naval station, New Orleans, and ordered to the navy yard, League Island, Pa., November 15.

Thompson E., surgeon, ordered to the navy yard, Charleston, S. C.

McDonald, P. E., P. A. surgeon, detached from the naval dispensary, Washington, D. C., and ordered to the *Dolphin*.

Plummer, R. W., P. A. surgeon, detached from the navy yard, Charleston, S. C., and ordered to the naval recruiting rendezvous, Kansas City, Mo., November 15.

Riggs, R. E., asst.-surgeon, ordered to the *Franklin*.

Michaels, R. H., asst.-surgeon, detached from the naval recruiting rendezvous, Kansas City, Mo., and ordered home to wait orders.

Diehl, O., surgeon, detached from the *Baltimore* and ordered home to wait orders.

Spear, R., surgeon, ordered to the Baltimore.

Pryor, J. C., surgeon, detached from the naval medical school, Washington, D. C., and ordered to the naval dispensary, Washington, D. C.

Brownell, C. de W., surgeon, ordered to the naval recruiting rendezvous, Providence, R. I.

Richards, T. W., surgeon, ordered to the naval hospital, Norfolk, Va.

Thompson, J. C., surgeon, detached from the naval recruiting rendezvous, Providence, R. I., and ordered to the Asiatic station, via the *Lawton*, sailing December 1.

Murphy, J. F., asst.-surgeon, detached from the naval recruiting rendezvous, Buffalo, N. Y., and ordered to Washington, D. C., December 4, for examination for promotion, and then to wait orders.

Guthrie, J. A., asst.-surgeon, detached from the navy yard, League Island, Pa., and ordered to the naval recruiting rendezvous, Buffalo, N. Y.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 8.

Lavinder, C. H., P. A. surgeon, granted leave of absence for one month from November 6.

McMullen, John, P. A. surgeon, granted leave of absence for one month from November 7.

Currie, D. H., P. A. surgeon, relieved from special temporary duty in New Orleans and from temporary duty in San Francisco, and directed to proceed to San Francisco quarantine station for duty.

Amesse, J. W., P. A. surgeon, relieved from special temporary duty in New Orleans and from duty in Seattle, Wash., and directed to proceed to Ellis Island, N. Y., reporting to medical officer in command for duty.

Berry, T. D., P. A. surgeon, granted leave of absence for one month to take effect from date of being relieved in New Orleans.

Rucker, W. C., assistant surgeon, granted leave of absence for seven days.

Collins, Geo. L., assistant surgeon, leave of absence granted Assistant Surgeon Collins for sixteen days from October 31, 1905, amended to read sixteen days from November 1.

Ashford, F. A., asst.-surgeon, granted leave of absence for five days from November 4, under provisions of paragraph 191, regulations.

Mullan, E. H., asst.-surgeon, granted leave of absence for five days from November 2.

Mullan, E. H., asst.-surgeon, granted extension of leave of absence for five days, from November 7.

de Valin, Hugh, asst.-surgeon, relieved from special temporary duty at New Orleans and directed to proceed to Baltimore, reporting to medical officer in command for duty and assignment to quarters.

Alexander, E., acting asst.-surgeon, granted leave of absence for six days from November 10.

Cleaves, F. H., acting asst.-surgeon, granted leave of absence for five days, beginning November 6.

Goldsborough, B. W., acting assistant surgeon, granted leave absence for two days from November 4.

Missouri.

"Adequate and uniform precautions can not be taken unless under the direction of some central authority. This means that the whole scheme of quarantine at the great ports of the country should be under charge of the national authorities. . . . National quarantine is what the country wants for all its ports, and the coming Chattanooga conference ought to start a movement which will secure congressional legislation along that line."—St. Louis *Globe-Democrat.*

"Governor Blanchard expresses himself as being in favor of federal control of maritime quarantines and is also inclined toward such control of interstate quarantines."—From an interview with Governor Blanchard of Louisiana.

Mississippi.

"For the protection of the coast—seaports—I am in favor of vesting absolute authority in the federal government."—From *an interview with Governor Vardaman.*

Tennessee.

"As a matter of economy, then, as well as policy, desirability and safety, as explained yesterday, the entire South should take up this federal marine quarantine at once and use its best endeavors to induce the government to establish it at the earliest possible moment."—Memphis *Commercial-Appeal.*

"The board of health of Pensacola, Fla., has adopted strong resolutions favoring national control of quarantine regulations at all southern seaports and urges the Florida congressional delegation to urge the same. The sentiment expressed by the people of Pensacola has become very general in the south since this last outbreak of fever at New Orleans, and there are strong reasons for believing that the opposition hitherto manifested by southern representatives will be withdrawn and the principle of national control of quarantine established. The press of the south is very nearly unanimous for the proposition."—Chattanooga *Times.*

"There is a growing sentiment in the South, and all over the country as for that, for a federal quarantine law. The *News,* like a great many other newspapers in the South, has not jumped into this popular wave and demanded that a law be passed at the next session of congress establishing federal quarantine, but under sensible regulations we believe that such a plan would be best for the whole country."—Chattanooga *News.*

"In view of these facts, it is declared to be the sense of the Pensacola board of health 'that the quarantine of all seaport towns should be under the charge and control of the general government.' The *American* unqualifiedly indorses the conclusion of the Pensacolans. It has long been the opinion of this newspaper that the general government is the only power capable of handling quarantine matters in such emergencies." —Nashville *American.*

Texas.

"Indeed, now that the importance of a strict quarantine is appreciated, and to avoid those embarrassments which proceed from conflicts of state laws and quarantine, the whole matter of public health, as far as contagious or infectious diseases are concerned, may be turned over to the federal government, with the consent of the states."—Galveston *News* and Dallas *News.*

Northern Opinions.

"Sentiment in favor of a national quarantine service appears to be practically unanimous among those who are able to take an unprejudiced view of the matter. The Philadelphia *Press* remarks that the more rapid, the more complete and the more sweeping the change from the patchwork state quarantines wrangling on the Gulf to federal authority the better. State quarantine has lasted its day. It is an expensive and useless nuisance. It is no more needed than state harbor lights, a state immigrant service or any other regulation of foreign or interstate commerce. The day for shotgun quarantine has passed in this country. The New York *Evening Post* thinks that a national quarantine service is brought distinctly nearer by the appeal of Louisiana to the federal government and suggests that congress will undoubtedly be called on to make the powers and the duties of the national government larger and more precise in all that relates to oversight of the public health. These views are in entire accord with what was said by the *Bee* some days ago. . . . The demand that is being made for a national quarantine service should not be allowed to die out with the subsidence of the yellow fever, but should be pressed on congress until there is legislation giving the national government absolute control over quarantine. Existing law does not go far enough."—Omaha (Neb.) *Bee.*

"The question of physical health is put first, and it is very important. An outbreak of yellow fever in the south, with no common purpose or provision to meet it, throws the people into a panic that produces scenes and acts of almost indescribable inhumanity. Shotgun quarantines are a disgrace to civilization, and the only remedy—if there is a remedy—is in concert of action and standing means to meet such emergencies. The national power should be invoked."—Washington (D. C.) *Star.*

"In no section of the United States is the principle of home rule as formulated in the doctrine of state rights so firmly established as in the South. Southern communities are tenacious of their local police powers. This being so, some surprise may be felt at the unanimity of the sentiment now prevalent throughout the portion of the South which has experienced or feared the yellow fever in epidemic form in favor of the surrender of their quarantine system to the federal government and of turning over the campaign against the mosquito to the Marine-Hospital Service."—New York *Times.*

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

STATUS OF GASTRECTOMY.

NORTH PLATTE, NEB., Nov. 8, 1905.

To the Editor:—I would like to know through THE JOURNAL the present status of the operation of removing the whole stomach and whether the operation has ever been performed with satisfactory results. D. T. QUIGLEY.

ANSWER.—The entire stomach has now been removed several times for carcinoma and patients have lived for from several months to two years, usually dying from metastatic carcinoma. Cases suitable for total removal of the stomach are, of course, rare. So far as the functional results are concerned after complete removal of the stomach, they have been satisfactory.

POSTGRADUATE COURSE IN BERLIN.

WORTHINGTON, MINN., Nov. 9, 1905.

To the Editor:—In THE JOURNAL, November 4, you gave a brief review of a post-graduate course to be given in Berlin next spring at the time of the dedication of the "Empress Friedrich House." Can you give me the time when these lectures will take place and the address of some one with whom I can correspond for further information? HENRY WIEDOW.

ANSWER.—The cycle of lectures is to be given during March and April, 1906. Professor R. Kutner is general secretary of the postgraduate movement (Zentralkomitee für das ärztliche Fortbildungswesen). His address is Elssholzstrasse 13, Berlin W. 30. He is editor of the journal issued by the central committee. His report for the five years since the committee was organized was recently published by J. S. Preuss, Berlin, in a book of 114 pages, giving the details and work accomplished by the postgraduate movement in Prussia.

METHYLENE BLUE TEST FOR TYPHOID URINE.

PARKERSBURG, W. VA., Oct. 28, 1905.

To the Editor: A friend of mine has called my attention to a new test of the urine, methylene blue, in typhoid fever. Will you give some information about it, where we can find literature concerning it, etc.? W. H. SHARP.

ANSWER.—The test is sometimes called Russo's test. The original paper is found in *Riforma Medica,* vol. xxi, No. 19, 1905. A partial abstract of the paper appears in THE JOURNAL, vol. xlv, 1905, p. 363. The technic of the test is very simple and is as follows: Four drops of a 1 to 1,000 aqueous solution of methylene blue are added to 4 or 5 c.c. of suspected urine. If the reaction is positive the mixture turns to an emerald or mint green hue. A light green or bluish green tint shows a negative reaction. The positive reaction is not affected by boiling the urine or the previous ingestion of such compounds as phenacetin, salol, quinin, calomel, etc. It is given as early as the second day of the disease and persists throughout its course. The mint green hue is first noted and the emerald green hue appears as the disease progresses. If the course is favorable the tone becomes more and more bluish, while if unfavorable the emerald tint persists. The chief point in favor of the test is its simplicity. It is also quite as reliable as the diazo reaction of Ehrlich. It is, however, given in cases of measles, smallpox, chronic and suppurative tuberculosis. It is not given in varioloid, varicella, scarlet fever, miliary tuberculosis, appendicitis and other conditions. The difficulty in the application of the test comes in the ability to recognize the various tints of green which may be present. With a little practice, however, the positive reaction may be readily detected. The fact that the test is not given in a miliary tuberculosis, appendicitis, varicella, etc., makes it invaluable as an aid in differential diagnosis.

State Boards of Registration

COMING EXAMINATIONS.

Board of Registration in Medicine in Massachusetts, State House, Boston, November 4-15. Secretary, E. B. Harvey, Boston.

Connecticut Medical Examining Board, City Hall, New Haven, November 14-15. Secretary, Charles A. Tuttle, New Haven.

State Board of Health of Louisiana, New Orleans, November 14-15. Secretary, F. A. Larue, New Orleans.

State Board of Health of West Virginia, Clarksburg, November 14-16. Secretary, H. A. Barbee, Pt. Pleasant.

Wyoming Board of Medical Examiners, Cheyenne, December 6. Secretary, S. B. Miller, Laramie.

Examining Board representing the President and Fellows of the Medical Society of Delaware at Dover, and the Homeopathic Board, Wilmington, December 12. Secretary, P. W. Tomlinson, Wilmington.

Ohio State Board of Medical Registration and Examination, Columbus, December 12-14. Secretary, F. Winders, Columbus.

Medical Examining Board of Virginia, Richmond, December 12-15. Secretary, R. S. Martin, Stuart.

State Board of Health of Missouri, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

Board of Medical Examiners State of California, San Francisco, December 20. Secretary, Charles L. Tisdale, San Francisco.

Board of Medical Examiners of Maryland, Baltimore, December 13-16. Secretary, J. McScott, Hagerstown.

Montana October Report.—Dr. W. C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, Oct. 3-5, 1905. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 24, of whom 16 passed and 8 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending November 11:

Hess, Louis T., asst.-surgeon, ordered to Fort Lawton, Wash., for duty.

Collins, C. C., asst.-surgeon, ordered to Fort Walla Walla, Wash.

Pyles, Will L., asst.-surgeon, ordered to Jefferson Barracks, Mo., for duty.

Rafferty, Ogden, surg., granted two months' leave of absence.

Reynolds, Chas. R., asst.-surgeon, assigned to duty as surgeon on transport *Logan*, next voyage to Manila, where, on arrival, he will report to commanding general, Philippines Division, for assignment to duty.

Wadhams, S. H., asst.-surg., granted 30 days' leave of absence, with permission to apply for 30 days' extension.

Adair, Geo. W., asst.-surgeon general, granted 15 days' leave of absence.

DeWitt, Wallace, asst.-surgeon, granted 30 days' leave of absence.

Frick, Euclid B., surgeon, ordered to assume temporary charge of chief surgeon's office, Department of Dakota, during the absence of Col. Adair, on leave of absence.

Edwards, Jas. F., asst.-surgeon, granted leave of absence from November 17th to and including December 31, 1905. His resignation as an officer of the army has been accepted by the President, to take effect December 31.

Purnell, Julius M., contract surgeon, ordered to Alcatraz Island, Cal., for temporary duty.

Barney, Fred M., contract surgeon, arrived at Fisherman's Point, Cuba, for duty.

Daywalt, George W., contract surgeon, left Fort St. Philip, La., on sick leave for seven days.

Waddell, Ralph W., dental surgeon, arrived at Fort Crook, Neb., for duty.

Boak, S. Davis, dental surgeon, left Fort Washington, Md., on leave of absence.

Carpenter, Alden, dental surgeon, arrived at Boise Barracks, Idaho, for duty.

Ames, Roger P., contract surgeon, arrived at Fort Saint Philip, La., for duty.

Jones, George H., contract surgeon, returned to duty at Fort Fremont, S. C., from leave of absence.

Byars, Caspar R., contract surgeon, returned to Fort Sam Houston, Texas, from duty at Fort Sill, Okla.

Dickenson, Clarence F., contract surgeon, left Fort Logan, Colo., and arrived at Fort Douglas, Utah, to accompany 22d Battery, Field Artillery, on overland march to Fort Riley, Kans.

Slater, Ernest F., contract surgeon, arrived at Washington Barracks, D. C., for temporary duty.

Adair, George F., contract surgeon, left Fort Wadsworth, N. Y., on leave of absence for fifteen days.

Navy Changes.

Changes in the Medical Corps U. S. Navy, for the week ending November 11:

Riggs, C. E., surgeon, detached from the *Dolphin* and ordered home to wait orders.

Spratling, L. W., surgeon, detached from the naval station, New Orleans, and ordered to the navy yard, League Island, Pa., November 15.

Thompson E., surgeon, ordered to the navy yard, Charleston, S. C.

McDonald, P. E., P. A. surgeon, detached from the naval dispensary, Washington, D. C., and ordered to the *Dolphin*.

Plummer, R. W., P. A. surgeon, detached from the navy yard, Charleston, S. C., and ordered to the naval recruiting rendezvous, Kansas City, Mo., November 15.

Riggs, R. E., asst.-surgeon, ordered to the *Franklin*.

Michaels, R. H., asst.-surgeon, detached from the naval recruiting rendezvous, Kansas City, Mo., and ordered home to wait orders.

Diehl, O., surgeon, detached from the *Baltimore* and ordered home to wait orders.

Spear, R., surgeon, ordered to the Baltimore.

Pryor, J. C., surgeon, detached from the naval medical school, Washington, D. C., and ordered to the naval dispensary, Washington, D. C.

Brownell, C. de W., surgeon, ordered to the naval recruiting rendezvous, Providence, R. I.

Richards, T. W., surgeon, ordered to the naval hospital, Norfolk, Va.

Thompson, J. C., surgeon, detached from the naval recruiting rendezvous, Providence, R. I., and ordered to the Asiatic station, [illegible] 'ling December 1.

[illegible] st.-surgeon, detached from the naval recruiting [illegible], N. Y., and ordered to Washington, D. C., December 4, for examination for promotion, and then to wait orders.

Guthrie, J. A., asst.-surgeon, detached from the navy yard, League Island, Pa., and ordered to the naval recruiting rendezvous, Buffalo, N. Y.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 8.

Lavinder, C. H., P. A. surgeon, granted leave of absence for one month from November 6.

McMullen, John, P. A. surgeon, granted leave of absence for one month from November 7.

Currie, D. H., P. A. surgeon, relieved from special temporary duty in New Orleans and from temporary duty in San Francisco, and directed to proceed to San Francisco quarantine station for duty.

Amesse, J. W., P. A. surgeon, relieved from special temporary duty in New Orleans and from duty in Seattle, Wash., and directed to proceed to Ellis Island, N. Y., reporting to medical officer in command for duty.

Berry, T. D., P. A. surgeon, granted leave of absence for one month to take effect from date of being relieved in New Orleans.

Rucker, W. C., assistant surgeon, granted leave of absence for seven days.

Collins, Geo. L., assistant surgeon, leave of absence granted Assistant Surgeon Collins for sixteen days from October 31, 1905, amended to read sixteen days from November 1.

Ashford, F. A., asst.-surgeon, granted leave of absence for five days from November 4, under provisions of paragraph 191, regulations.

Mullan, E. H., asst.-surgeon, granted leave of absence for five days from November 2.

Mullan, E. H., asst.-surgeon, granted extension of leave of absence for five days, from November 7.

de Valin, Hugh, asst.-surgeon, relieved from special temporary duty at New Orleans and directed to proceed to Baltimore, reporting to medical officer in command for duty and assignment to quarters.

Alexander, E., acting asst.-surgeon, granted leave of absence for six days from November 10.

Cleaves, F. H., acting asst.-surgeon, granted leave of absence for five days, beginning November 6.

Goldsborough, B. W., acting assistant surgeon, granted leave of absence for two days from November 4.

Stevenson, J. W., acting assistant surgeon, granted leave of absence for thirty days from November 6.

Tappan, J. W., acting assist.-surgeon, granted seven days leave of absence from November 6, under provisions of paragraph 191, regulations.

McDonald, Jeannette, medical inspector, granted leave of absence for eighteen days, from October 23.

Stearns, W. L., pharmacist, granted three days leave of absence effective from date of being relieved.

Goodman, F. S., pharmacist, granted leave of absence for twenty days from December 12.

Thurston, E. J., pharmacist, granted leave of absence for fifteen days, from November 10.

Spangler, L. C., pharmacist, granted leave of absence for thirty days from November 5.

BOARD CONVENED.

A board of officers was convened to meet at the Bureau on call of chairman for physical examination of Chief Engineer H. F. Schoenborn, R. C. S. Assistant Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon H. McG. Robertson, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the surgeon general, Public Health and Marine-Hospital Service, during the week ended November 13:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 21 28, 5 cases.
Louisiana: New Orleans, Oct. 21-28, 5 cases.
Michigan: Kalamazoo, Oct. 27-Nov. 4, 2 cases.
Ohio: Springfield, Oct. 26-Nov. 3, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Sept. 16-23, 1 case.
Brazil: Para, to Oct. 14, 56 cases, 14 deaths; Rio de Janeiro, Sept. 17-Oct. 8, 36 cases, 9 deaths.
Canada: Toronto, Oct. 28-Nov. 4, 1 case.
Chile: Antofagasta, Oct. 14, 65 cases, 18 deaths; Coquimbo, 16 cases, 5 deaths; Iquique, Sept. 30-Oct. 7, 23 cases, 5 deaths.
Cuba, La Salud, Oct. 28, 1 case, imported from Canary Islands.
Ecuador: Guayaquil, Oct. 3-17, 12 deaths.
Great Britain: Liverpool, Oct. 14-21, 7 cases.
India: Madras, Sept. 30-Oct. 6, 3 deaths.
Italy: General, Oct. 12-19, 16 deaths; Catania, Oct. 5 12, 2 deaths.
Mexico: City of Mexico, Aug. 26-Oct. 21, 26 cases, 12 deaths.
Russia: Odessa, Oct. 7-14, 8 cases, 1 death.
Spain: Barcelona, Oct. 10-20, 4 deaths.
Turkey: Constantinople, Oct. 1-15, 5 deaths.

YELLOW FEVER—UNITED STATES.

Florida: Pensacola, Aug. 29-Nov. 3, 555 cases, 78 deaths.
Louisiana: Assumption Parish, to Oct. 21, 48 cases, 2 deaths; East Carroll Parish, to Oct. 26, 341 cases, 41 deaths; Iberia Parish, to Oct. 21, 14 cases, 1 death; Jefferson Parish, to Nov. 3, 507 cases, 55 deaths; Lafourche Parish, to Nov. 3, 447 cases, 60 deaths; Orleans Parish, New Orleans, July 21-Nov. 8, 3,389 cases, 459 deaths.
Mississippi: Vicksburg and vicinity, Aug. 30-Nov. 4, 180 cases, 27 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Sept. 17 Oct. 8, 9 cases, 3 deaths.
Ecuador: Guayaquil, Oct. 10-17, 1 death.
Honduras: Choloma, Oct. 17-24; 3 cases, 1 death; San Pedro, 2 cases.
Mexico: Coatzacoalcos, Oct. 22-28, 1 case; Omealca, 4 cases, 4 deaths; Tezonapa, Oct. 22-28, 1 case, 1 death; Tierra Blanca, 1 case, 1 death; Tuxtepec, 7 cases, 6 deaths; Vera Cruz, 2 cases.
Panama: Bocas del Toro, Oct. 14-21, 2 cases.
Venezuela: Maracaibo, Aug. 20-27, 1 case, 1 death.

CHOLERA—FOREIGN.

Germany: General, to Oct. 21, 280 cases; 90 deaths.
India: Madras, Sept. 29-Oct. 6, 119 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 30, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Sept. 17-Oct. 8, 37 cases, 17 deaths.
India: General, Sept. 16-23, 4,695 cases, 3,192 deaths; Bombay, Oct. 3 10, 26 deaths; Karachi, Oct. 1-8, 19 cases, 18 deaths.
Peru: Lima, Sept. 21-30, 4 cases, 2 deaths; Mausche, 3 cases, 2 deaths; Paita, 3 cases.

Medical Organization

Public Lecture on Disease and Hygiene.

The Oakland (Cal.) *Enquirer* inquires: "The Chicago Medical Society is offering a series of free public lectures. Why are such things denied the people of this city? Are not physicians of Oakland as able, progressive and public spirited as those of Chicago?" The people of every city are entitled to such lectures. The county medical society has the machinery to provide them.

California and Texas.

Dr. McCormack's Western Trip.—Dr. McCormack continues his western tour. Reports from *California* indicate a varying degree of response on the part of the profession, but agree that a very great deal of good has been accomplished. October 24 Dr. McCormack addressed a joint meeting of the Santa Barbara, Monterey and San Luis Obispo (Cal.) county medical societies. At Pasadena, October 26, he addressed a meeting of the Pasadena branch of the Los Angeles County Medical Society. From California Dr. McCormack entered Texas, addressing meetings at El Paso, October 30, and at San Antonio on November 1. The latter was the semi-annual meeting of the Fifth Councilor District Medical Society, and the program included papers by Dr. John B. Deaver and Dr. Joseph Price of Philadelphia and Dr. Lewis McMurtry of Louisville. There was a two days' session and over one hundred members were in attendance. Dr. McCormack addressed the physicians of Austin on November 3, and was to have addressed the Jefferson County Medical Society on November 4, but a delay caused cancellation of that engagement. He met with the Galveston County Medical Society November 6, and on the following day addressed the Harris County Medical Society at Houston.

AMERICAN ACADEMY OF MEDICINE.

Thirtieth Annual Meeting, held in Chicago, Nov. 9-10, 1905.

The President, Dr. Winfield S. Hall, Chicago, in the Chair.

Report of Committee on Laws Regulating the Practice of Medicine.

Dr. Charles McIntire, Easton, Pa., secretary, presented the details of the changes in the laws and the statistical part of the report in printed form. The academy began the study of laws relating to the practice of medicine in 1880, and the report gives some of the results of this 25 years' investigation. Some of the imperfections of these laws are: 1. The lack of uniformity. 2. The relation of vagarious practitioners. Each state, by special legislation, by exemption in general legislation, or by sufferance, permits certain classes of people to perform the office of a physician without the tests required by the state for doctors in medicine. The report suggests that the general practice acts should recognize this by providing for "limited licentiates in medicine," who would be examined only on the elementary subjects. As these laws are to protect the people, they should not take cognizance of any special system. Each one should have liberty to treat disease after his own sweet will, but only after he has demonstrated to the state officials that he possesses such knowledge as the legislature has decided is necessary for the proper protection of the citizens. 3. The laws do not accept the statement of the medical college as final. This has been thought to have been necessary because some medical schools have been found not to have acted in good faith. The result is a somewhat mechanical statement of requirements. Time will right this, and the future laws will accept a diploma without going behind the returns. 4. Another weakness is the provisions for the transfer of a legal practitioner from one state to another. The report suggests that authority be given to each board to accept the license of another state at its value and to make such additional tests as may be required. 5. The laws too frequently fail to protect those who are licensed. They should provide for some official whose duty it is to search out and prosecute the unlicensed and those who are abusing their licenses. The report favored having osteopaths represented on state medical examining boards.

DISCUSSION.

Dr. Carl H. von Klein, Chicago, referred to the gradual evolution that is taking place toward higher medical education. America is not behind in this progressive movement. In some medical schools the courses of instruction are equal to those established in foreign countries, but the preliminary education of American medical students has not reached as high a standard in this as it has in foreign countries.

Dr. Leartus Connor, Detroit, called attention to the origin of medical laws, who originated them, and for what purpose. He said there are two parties involved—*first*, the people, and, *second*, the physicians themselves. Physicians can not enact laws themselves, but they join with the people in accomplishing this. But physicians have been the prime factors in establishing these laws, sometimes with a selfish purpose in view. He thinks that if physicians had looked disinterestedly after the interests of the people first, rather than their own interests, there would have been no need of any medical laws.

Dr. B. D. Harison, Sault Ste. Marie, Mich., did not agree with the recommendation in the report that osteopaths should be admitted as members of state medical examining boards, and recognized as a part of the medical profession. The Supreme Court of Kentucky holds that the osteopath is a masseur. It is held by the Supreme Court of another state that osteopathy comes within the field of medicine. He referred to the Michigan law regarding osteopathy and osteopaths, and said it is only a matter of time when osteopaths will be driven out of that state. He favors letting them alone, as they will work out their own salvation or damnation.

Dr. R. O. Beard, Minneapolis, believes that if we raise the standard of the medical profession we will not need medical legislation half so much as it is needed now. It is a question of the "survival of the fittest," and he thinks it will not be very long, after the medical profession has attained that standard of educational and professional fitness, before the bogus colleges will be relegated to the position of barbers, plumbers, etc. The legislative side of the question is more difficult to deal with, as physicians are not expert and successful in securing the enactment of laws.

Dr. John M. Dodson, Chicago, said that, urged by the medical profession, some literary schools have arranged their work so as to prepare young men better for the study of medicine. Some institutions of general learning are now pursuing the plan of supplying courses in chemistry, physics, general biology, and others in human anatomy, histology, bacteriology and embryology. The work they are doing should be recognized for what it is worth and not be arbitrarily rejected. He believes that the position which the Minnesota State Board of Medical Examiners has taken, in regard to examining graduates from other states than Minnesota, is absolutely untenable from a legal point of view, inasmuch as the Minnesota law does not say that a student shall have spent four years in a medical college, but says the student must have spent four years in the study of medicine in a recognized college. He thinks the whole question resolves itself into an interpretation of the law by the board, which is applied to the college instead of the individual.

Report of the Committee to Tabulate the Value of the First Degree.

Dr. Donly C. Hawley, Burlington, said that the committee found it necessary to make a prefatory study before attempting the definite work assigned to it. This study included two questions: 1. What is a college course intended to do? 2. What are the elements which, when compounded, make the physician? 1. A college is a factory where the value of the finished product depends on the character of the raw material furnished. It also depends on the process employed; but no process will cause a transmutation of metals. Unless the gold be in the ore, none can be found in the end-products. 2. To obtain material on which to base the answer to this question, a circular letter was sent to a large number of physicians, medical teachers and others, and college presidents. The replies received were studied by the committee, and are also included in the report as an appendix.

The questions were: 1. What is the character to be desired of the neophyte in medicine? To what extent can it be developed by educational processes? And what class of studies is adapted to bring it about? 2. What mental discipline is essential that a student may profitably benefit by a medical course? 3. What facts should be in possession of the intending medical student before he enters on his medical studies? Can the acquisition of these facts be used to train the character and the mind?

It is admitted that sometimes the man with a limited training outstrips his fellow with greater scholastic advantage. There must be something underlying which educational processes can not supply. He must be self-reliant, able to arrive at fair conclusions based on accurate observation, and to follow such conclusions with confidence. He must also have a bull-dog tenacity, a love of seeking scientific facts apart from preconceived theories, and sympathy with mankind. These are foundations, and every trait which will make an honorable man and cultured gentleman will be helpful. Having a student of this type, what should be the mental discipline to produce the best result? He should be taught to observe accurately and to interpret honestly the results of observation, to know how to study, to think logically, and train his memory to be of ready service. He should be educated, first, for the man, then for the physician. And, on the whole, the course in colleges leading to the A.B. degree seems to be fitted for this better than any other course. Besides, the mind so furnished should be in possession of certain facts to be used directly in the prosecution of medical studies. These include a knowledge of elementary physics, that it may understand its application in physiology and elsewhere; such a knowledge of chemistry as to make it necessary to teach only medical chemistry in a medical course; and general biology that the student can understand the study of life processes in man in an intelligent manner.

DISCUSSION.

Prof. C. S. Losey, Northwestern University, Chicago, emphasized that part of the report of the committee that students preparing for medicine should be advised to elect or to select studies in their college course, so that they may have two or three years of work in chemistry and biology, and that they be advised to take up such studies as histology, embryology and comparative anatomy. Some institutions are pursuing such a course at the present time.

Dr. Leartus Connor, Detroit, said a four-year course of study in medicine will give a man a broader outlook; it will give him imagination to look forward to what he ought to become; to have a broad sympathetic outlook of those with whom he has to do. The service of the physician reaches far beyond the peddling of pills or the opening of abdomens. The practice of medicine requires a vigorous body, and a college course ought to show the student what sort of body he has; whether he can endure the long strain of days and nights, of anxious thought about critical cases, etc. A man can not go through college and mingle with others without becoming a thinking machine, more or less. The man who has not got a good imagination, who can not see his operation before him with his eyes shut, so to speak, is not an educated physician. He is a mechanism and not a doctor.

Dr. Carl H. von Klein, Chicago, emphasized the value of an academic training preliminary to the study of medicine. The man who is academically well trained, other things being equal, makes a good physician. A man should not be discouraged because he fails in his first examination, as there are notable instances of men who failed in their first examinations, yet subsequently became great. Among others, he instanced Bismarck.

Prof. H. B. Ward, University of Nebraska, said that the heterogeneous character of our educational system in the United States as a name means nothing; that there must be some other form of test applied, some other measure than the mere name of an institution, if we expect to get anything like uniformity in the preliminary preparation of students before their entrance on the study of medicine. Those who have not followed the development of modern college education are not aware of the extent to which, even in small colleges, the elective system has been introduced. Formerly a college course meant in the same section of country, or in a group of affiliated colleges, more or less, the same training; not only four years, but four years applied relatively to certain lines, with some philosophy, some mathematics, some science, some literature, and some history. The modern college has made a departure from this. Even the most conservative colleges have introduced different courses which go under different names, but which in many, if not in all, cases lead to the same degree, and in general the degrees of B.S. and B.A. are apparently on a par with reference to future training. He deplored the fact that there is not a series of recognized studies leading

Stevenson, J. W., acting assistant surgeon, granted leave of absence for thirty days from November 6.

Tappan, J. W., acting assist.-surgeon, granted seven days leave of absence from November 6, under provisions of paragraph 191, regulations.

McDonald, Jeannette, medical inspector, granted leave of absence for eighteen days, from October 23.

Stearns, W. L., pharmacist, granted three days leave of absence effective from date of being relieved.

Goodman, F. S., pharmacist, granted leave of absence for twenty days from December 12.

Thurston, E. J., pharmacist, granted leave of absence for fifteen days, from November 10.

Spangler, L. C., pharmacist, granted leave of absence for thirty days from November 5.

BOARD CONVENED.

A board of officers was convened to meet at the Bureau on call of chairman for physical examination of Chief Engineer H. F. Schoenborn, R. C. S. Assistant Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon H. McG. Robertson, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the surgeon general, Public Health and Marine-Hospital Service, during the week ended November 13:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 21 28, 5 cases.
Louisiana: New Orleans, Oct. 21-28, 5 cases.
Michigan: Kalamazoo, Oct. 27-Nov. 4, 2 cases.
Ohio: Springfield, Oct. 26-Nov. 3, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Sept. 16-23, 1 case.
Brazil: Para, to Oct. 14, 56 cases, 14 deaths; Rio de Janeiro, Sept. 17-Oct. 8, 36 cases, 9 deaths.
Canada: Toronto, Oct. 28-Nov. 4, 1 case.
Chile: Antofagasta, Oct. 14, 65 cases, 18 deaths; Coquimbo, 16 cases, 5 deaths; Iquique, Sept. 30-Oct. 7, 23 cases, 5 deaths.
Cuba, La Salud, Oct. 28, 1 case, imported from Canary Islands.
Ecuador: Guayaquil, Oct. 3-17, 12 deaths.
Great Britain: Liverpool, Oct. 14-21, 7 cases.
India: Madras, Sept. 30-Oct. 6, 3 deaths.
Italy: General, Oct. 12-19, 16 deaths; Catania, Oct. 5 12, 2 deaths.
Mexico: City of Mexico, Aug. 26-Oct. 21, 26 cases, 12 deaths.
Russia: Odessa, Oct. 7-14, 8 cases, 1 death.
Spain: Barcelona, Oct. 10-20, 4 deaths.
Turkey: Constantinople, Oct. 1-15, 5 deaths.

YELLOW FEVER—UNITED STATES.

Florida: Pensacola, Aug. 29-Nov. 3, 555 cases, 78 deaths.
Louisiana: Assumption Parish, to Oct. 21, 48 cases, 2 deaths; East Carroll Parish, to Oct. 26, 341 cases, 41 deaths; Iberia Parish, to Oct. 21, 14 cases, 1 death; Jefferson Parish, to Nov. 3, 507 cases, 55 deaths; Lafourche Parish, to Nov. 3, 447 cases, 60 deaths; Orleans Parish, New Orleans, July 21-Nov. 8, 3,389 cases, 459 deaths.
Mississippi: Vicksburg and vicinity, Aug. 30-Nov. 4, 180 cases, 27 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Sept. 17 Oct. 8, 9 cases, 3 deaths.
Ecuador: Guayaquil, Oct. 10-17, 1 death.
Honduras: Choloma, Oct. 17-24; 3 cases, 1 death; San Pedro, 2 cases.
Mexico: Coatzacoalcos, Oct. 22-28, 1 case; Omealca, 4 cases, 4 deaths; Tezonapa, Oct. 22-28, 1 case, 1 death; Tierra Blanca, 1 case, 1 death; Tuxtepec, 7 cases, 6 deaths; Vera Cruz, 2 cases.
Panama: Bocas del Toro, Oct. 14-21, 2 cases.
Venezuela: Maracaibo, Aug. 20-27, 1 case, 1 death.

CHOLERA—FOREIGN.

Germany: General, to Oct. 21, 280 cases; 90 deaths.
India: Madras, Sept. 29-Oct. 6, 119 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 30, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Sept. 17-Oct. 8, 37 cases, 17 deaths.
India: General, Sept. 16-23, 4,695 cases, 3,192 deaths; Bombay, Oct. 3 10, 26 deaths; Karachi, Oct. 1-8, 19 cases, 18 deaths.
Peru: Lima, Sept. 21-30, 4 cases, 2 deaths; Mausche, 3 cases, 2 deaths; Paita, 3 cases.
Zanzibar: Zanzibar, Oct. 28, present.

AMERICAN ACADEMY OF MEDICINE.

Thirtieth Annual Meeting, held in Chicago, Nov. 9-10, 1905.

The President, Dr. Winfield S. Hall, Chicago, in the Chair.

Report of Committee on Laws Regulating the Practice of Medicine.

Dr. Charles McIntire, Easton, Pa., secretary, presented *the details of the changes in the laws and the statistical part* of the report in printed form. The academy began the study of laws relating to the practice of medicine in 1880, and the report gives some of the results of this 25 years' investigation. Some of the imperfections of these laws are: 1. The lack of uniformity. 2. The relation of vagarious practitioners. Each state, by special legislation, by exemption in general legislation, or by sufferance, permits certain classes of people to perform the office of a physician without the tests required by the state for doctors in medicine. The report suggests that the general practice acts should recognize this by providing for "limited licentiates in medicine," who would be examined only on the elementary subjects. As these laws are to protect the people, they should not take cognizance of any special system. Each one should have liberty to treat disease after his own sweet will, but only after he has demonstrated to the state officials that he possesses such knowledge as the legislature has decided is necessary for the proper protection of the citizens. 3. The laws do not accept the statement of the medical college as final. This has been thought to have been necessary because some medical schools have been found not to have acted in good faith. The result is a somewhat mechanical statement of requirements. Time will right this, and the future laws will accept a diploma without going behind the returns. 4. Another weakness is the provisions for the transfer of a legal practitioner from one state to another. The report suggests that authority be given to each board to accept the license of another state at its value and to make such additional tests as may be required. 5. The laws too frequently fail to protect those who are licensed. They should provide for some official whose duty it is to search out and prosecute the unlicensed and those who are abusing their licenses. The report favored having osteopaths represented on state medical examining boards.

DISCUSSION.

Dr. Carl H. von Klein, Chicago, referred to the gradual evolution that is taking place toward higher medical education. America is not behind in this progressive movement. In some medical schools the courses of instruction are equal to those established in foreign countries, but the preliminary education of American medical students has not reached as high a standard in this as it has in foreign countries.

Dr. Leartus Connor, Detroit, called attention to the origin of medical laws, who originated them, and for what purpose. He said there are two parties involved—*first*, the people, and, *second*, the physicians themselves. Physicians can not enact laws themselves, but they join with the people in accomplishing this. But physicians have been the prime factors in establishing these laws, sometimes with a selfish purpose in view. He thinks that if physicians had looked disinterestedly after the interests of the people first, rather than their own interests, there would have been no need of any medical laws.

Dr. B. D. Harison, Sault Ste. Marie, Mich., did not agree with the recommendation in the report that osteopaths should be admitted as members of state medical examining boards, and recognized as a part of the medical profession. The Supreme Court of Kentucky holds that the osteopath is a masseur. It is held by the Supreme Court of another state that osteopathy comes within the field of medicine. He referred to the Michigan law regarding osteopathy and osteopaths, and said it is only a matter of time when osteopaths will be driven out of that state. He favors letting them alone, as they will work out their own salvation or damnation.

Dr. R. O. Beard, Minneapolis, believes that if we raise the standard of the medical profession we will not need medical legislation half so much as it is needed now. It is a question of the "survival of the fittest," and he thinks it will not be very long, after the medical profession has attained that standard of educational and professional fitness, before the bogus colleges will be relegated to the position of barbers, plumbers, etc. The legislative side of the question is more difficult to deal with, as physicians are not expert and successful in securing the enactment of laws.

Dr. John M. Dodson, Chicago, said that, urged by the medical profession, some literary schools have arranged their work so as to prepare young men better for the study of medicine. Some institutions of general learning are now pursuing the plan of supplying courses in chemistry, physics, general biology, and others in human anatomy, histology, bacteriology and embryology. The work they are doing should be recognized for what it is worth and not be arbitrarily rejected. He believes that the position which the Minnesota State Board of Medical Examiners has taken, in regard to examining graduates from other states than Minnesota, is absolutely untenable from a legal point of view, inasmuch as the Minnesota law does not say that a student shall have spent four years in a medical college, but says the student must have spent four years in the study of medicine in a recognized college. He thinks the whole question resolves itself into an interpretation of the law by the board, which is applied to the college instead of the individual.

Report of the Committee to Tabulate the Value of the First Degree.

Dr. Donly C. Hawley, Burlington, said that the committee found it necessary to make a prefatory study before attempting the definite work assigned to it. This study included two questions: 1. What is a college course intended to do? 2. What are the elements which, when compounded, make the physician? 1. A college is a factory where the value of the finished product depends on the character of the raw material furnished. It also depends on the process employed; but no process will cause a transmutation of metals. Unless the gold be in the ore, none can be found in the end-products. 2. To obtain material on which to base the answer to this question, a circular letter was sent to a large number of physicians, medical teachers and others, and college presidents. The replies received were studied by the committee, and are also included in the report as an appendix.

The questions were: 1. What is the character to be desired of the neophyte in medicine? To what extent can it be developed by educational processes? And what class of studies is adapted to bring it about? 2. What mental discipline is essential that a student may profitably benefit by a medical course? 3. What facts should be in possession of the intending medical student before he enters on his medical studies? Can the acquisition of these facts be used to train the character and the mind?

It is admitted that sometimes the man with a limited training outstrips his fellow with greater scholastic advantage. There must be something underlying which educational processes can not supply. He must be self-reliant, able to arrive at fair conclusions based on accurate observation, and to follow such conclusions with confidence. He must also have a bull-dog tenacity, a love of seeking scientific facts apart from preconceived theories, and sympathy with mankind. These are foundations, and every trait which will make an honorable man and cultured gentleman will be helpful. Having a student of this type, what should be the mental discipline to produce the best result? He should be taught to observe accurately and to interpret honestly the results of observation, to know how to study, to think logically, and train his memory to be of ready service. He should be educated, first, for the man, then for the physician. And, on the whole, the course in colleges leading to the A.B. degree seems to be fitted for this better than any other course. Besides, the mind so furnished should be in possession of certain facts to be used directly in the prosecution of medical studies. These include a knowledge of elementary physics, that it may understand its application in physiology and elsewhere; such a knowledge of chemistry as to make it necessary to teach only medical chemistry in a medical course; and general biology that the student can understand the study of life processes in man in an intelligent manner.

DISCUSSION.

Prof. C. S. Losey, Northwestern University, Chicago, emphasized that part of the report of the committee that students preparing for medicine should be advised to elect or to select studies in their college course, so that they may have two or three years of work in chemistry and biology, and that they be advised to take up such studies as histology, embryology and comparative anatomy. Some institutions are pursuing such a course at the present time.

Dr. Leartus Connor, Detroit, said a four-year course of study in medicine will give a man a broader outlook; it will give him imagination to look forward to what he ought to become; to have a broad sympathetic outlook of those with whom he has to do. The service of the physician reaches far beyond the peddling of pills or the opening of abdomens. The practice of medicine requires a vigorous body, and a college course ought to show the student what sort of body he has; whether he can endure the long strain of days and nights, of anxious thought about critical cases, etc. A man can not go through college and mingle with others without becoming a thinking machine, more or less. The man who has not got a good imagination, who can not see his operation before him with his eyes shut, so to speak, is not an educated physician. He is a mechanism and not a doctor.

Dr. Carl H. von Klein, Chicago, emphasized the value of an academic training preliminary to the study of medicine. The man who is academically well trained, other things being equal, makes a good physician. A man should not be discouraged because he fails in his first examination, as there are notable instances of men who failed in their first examinations, yet subsequently became great. Among others, he instanced Bismarck.

Prof. H. B. Ward, University of Nebraska, said that the heterogeneous character of our educational system in the United States as a name means nothing; that there must be some other form of test applied, some other measure than the mere name of an institution, if we expect to get anything like uniformity in the preliminary preparation of students before their entrance on the study of medicine. Those who have not followed the development of modern college education are not aware of the extent to which, even in small colleges, the elective system has been introduced. Formerly a college course meant in the same section of country, or in a group of affiliated colleges, more or less, the same training; not only four years, but four years applied relatively to certain lines, with some philosophy, some mathematics, some science, some literature, and some history. The modern college has made a departure from this. Even the most conservative colleges have introduced different courses which go under different names, but which in many, if not in all, cases lead to the same degree, and in general the degrees of B.S. and B.A. are apparently on a par with reference to future training. He deplored the fact that there is not a series of recognized studies leading toward medicine as there is toward theology, law and other vocations.

PROF. JAMES G. NEEDHAM, Lake Forest University, favors teaching general biology in colleges, letting the medical schools teach it as it applies to the human body. He would have the colleges teach general embryology and vertebrate embryology, but let the medical schools teach those aspects of embryology that apply to the human being and to the practice of medicine. The same should be done in other subjects. These colleges can teach certain branches to greater advantage than they are now being taught in medical schools.

DR. BURTON D. MYERS, University of Indiana, said he has been studying seriously the best means of developing and furnishing a preliminary education. The aim of those in authority in this university is not to establish another medical school, but a medical department of the better kind, and they are ready to require four years of collegiate work, if they are convinced that this would be essential. The man who enters on the practice of medicine ought to be able to use the English language correctly, to express himself clearly and concisely. He ought to be able to read French and German.

The report was further discussed by Drs. Daniel T. Nelson, John M. Dodson, Professor Halsey, R. O. Beard, and B. D. Harison.

The committee asked that the report be referred to the council for action and recommendation as to whether the investigation shall be continued, and it was so done.

Report of the Committee on Teaching Hygiene.

DR. HELEN C. PUTNAM, Providence, R. I., visited over seventy classes in domestic science in 18 different cities and about as many in nature study, in elementary, high, normal and special public schools. The actual practice of principles of hygiene in domestic science and the actual observation of biologic details and physical phenomena in the teaching of the sciences (called nature study in elementary schools) were briefly compared with the method of memorizing from books and talks. The committee reserved its recommendations until it has reported on the other direct methods of teaching hygiene in the public schools.

Altruism in the Medical Profession.

DR. WINFIELD S. HALL, Chicago, stated that the first law of life is the preservation of self; but the second and higher law is the preservation of others. He summed up the biologist's interpretation of egoism and altruism in the following general principles: (1) All the activities of living organisms may be classified as egoistic, those that nourish and protect the individual; and altruistic, those that maintain and protect the race. (2) Altruistic activities invariably involve on the part of the individual sacrifice of self for the good of the race. Every profession, every occupation, in life affords its opportunities for altruism, but he who chooses the medical profession must do so with the knowledge that to be a useful and successful member of that profession he must subordinate self to the welfare of his fellow-men. The true physician is solicitous, above all, for the patient's welfare, and not only ministers to his immediate needs, but seeks so to instruct him that, when restored to health, he may, by right living, maintain it continuously, thus needing no further professional service from his physician. This is a manifestation of altruism so nearly universal in the medical profession that the physician loses caste in his profession if he fails in the discharge of this obligation. A higher degree of altruism is manifested by those who sacrifice a gain commensurate with their abilities in order to inspire, guide and uplift the youth. The work of the true teacher is always altruistic. The teacher must always take a part of his remuneration in the satisfaction which he derives from the molding of a character and in the joy which he experiences in the inspiration of lofty ambition.

The higher the order of altruism, the fewer there are who attain it. Voluntary sacrifice of life in order that other lives may be saved is the highest order of altruism. This height of sacrifice has been attained by a comparatively small number only; a number, however, that should include the names of many unknown heroes who have gone to their death while ministering to the sick in plague-stricken places, leaving no record of their heroism. Organized for the purpose of advancing the standards of medical education, of advancing the boundaries of medical science, of elevating the profession and of preventing disease, the work of the American Academy of Medicine has been altruistic from the time of its organization to the present. The field of its activities is ever widening and always along altruistic lines. If he were asked to make a general recommendation, it would be that the academy accept as its field of endeavor the altruistic responsibilities and activities of the medical profession, definitely outlining a program of research to be prosecuted along various lines, such as education, school hygiene, state medicine, ethics, etc. This research should be followed by carefully directed and persistent effort to accomplish that which the research reveals to be advantageous to society.

DR. CASEY A. WOOD, Chicago, delivered an interesting lecture, which was elaborately illustrated by numerous colored stereopticon slides, on the "Eyes and Eyesight of the Lower Animals."

Officers.

The following officers were elected: President, Dr. Donly C. Hawley, Burlington, Vt.; vice-presidents, Drs. Helen C. Putnam, Providence, R. I.; George W. McCaskey, Fort Wayne, Ind.; Henry B. Favill, Chicago, and James T. Searcy, Tuscaloosa, Ala.; secretary and treasurer, Dr. Charles McIntire, Easton, Pa.; assistant secretary, Dr. Samuel C. Stanton, Chicago.

The next meeting will be held in Boston, June 2 and 4, 1906.

(To be continued.)

MEDICAL SOCIETY OF THE STATE OF DELAWARE.

Annual Meeting, held in Wilmington, Oct. 10, 1905.

The president, Dr. Alexander Lowber, Wilmington, in the Chair.

(Continued from page 1254.)

Sanatorium Treatment of Consumption.

DR. ALEXANDER LOWBER, Wilmington, in his annual address, stated that, during the year 1900, there were 110,000 deaths from consumption in the United States. He urged teaching the general public that tuberculosis is an inoculable disease, conveyed largely through the agency of the sputum; the avoidance of promiscuous expectoration; the necessity for proper disinfection by the state boards of health; the sanitary supervision of workshops, places of public resort, hotels, steam and trolley cars, etc. Early diagnosis, informing the patient of the nature of his illness, and the treatment of the general condition of the patient, are essential factors, as the further advanced the disease is the less chance there is for recovery. Sanatorium treatment is essential, and among the important features thereof he mentioned constant life in the open air; sleeping either in the open air or in a room sufficiently open on all sides; good feeding; judicious exercises; stimulation of the vital forces, and special respiratory exercises to increase the lung capacity, together with special, individual instructions to every patient. He enumerated the number of sanitariums in the different states and territories, as well as in foreign countries, and gave a résumé of the work they had accomplished.

DISCUSSION.

DR. J. J. BLACK, New Castle, urged that the profession appeal to the legislature in order to secure the establishment of a state sanatorium. The place to attack consumption is in the slums, among the indigent and ignorant. Much can be done to prevent the spread of the disease by educating these people to the proper care of themselves and the proper precautions necessary for the safety of others. He did not believe that climate had much influence on the effect of the sanatorium treatment.

DR. GEORGE WILLIAM MARSHALL, Milford, stated that he believed the chief reason the state sanatorium had not been established was the lack of funds in the state treasury.

DR. A. ROBIN referred to the practice, when the sanatorium treatment is begun, of giving the patient a large number of eggs, which are sometimes indigestible, owing to the large amount of hydrochloric acid and gastric juice required for their proper assimilation. He believed that the reason a meat diet is so successful is because it stimulates the secretion of the gastric juice and produces more hydrochloric acid.

Dr. W. H. Hancker, Farmhurst, stated that in the institution established for the care of the tubercular insane they had cured nearly all the cases referred to them, with the exception of those in the very advanced stages, the treatment employed being outdoor exercise, plenty of fresh air, nourishment and a meat diet, in conjunction with the eggs.

Autointoxication as a Causative Factor in Disease.

Dr. Albert Robin, Wilmington, classified autointoxication as endogenous and exogenous. Endogenous autointoxication includes the toxins generated by the various tissue cells in the course of their normal biologic activity, the so-called cytotoxins, and the poisons formed during nutrition metabolism. Exogenous autointoxication is caused by the poisons generated in the gastrointestinal tract as a result of bacterial action, as well as the specific toxins generated by bacteria. The cytotoxins are closely related to the bacterial toxins and they cause disease in the same manner. Their continuous menace to the organism is overcome by the antitoxins which are continuously generated in the body by certain cells, probably those of the ductless glands. When this natural immunizing balance is disturbed, disease is the result. Nephritis, hepatic cirrhosis, and various nervous diseases are probably caused by the failure of the organism to neutralize its own toxins. The metabolic poisons generated in the course of normal nutrition are oxidized in the liver and eliminated through the emunctories. Failure of such oxidation and elimination causes disease. The exogenous poisons and toxins are also neutralized by immunizing substances, oxidized in the liver and eliminated through the emunctories. Autointoxication, therefore, may result (1) from non-neutralization of the cytotoxins which are normal end-products of cellular life; (2) from failure on the part of the liver to destroy the poisonous products of metabolism (hepatic insufficiency); (3) from the failure on the part of the kidneys to eliminate the free toxins (renal insufficiency), and (4) from gastrointestinal disturbances which favor intestinal fermentation. The rational treatment of autointoxication resolves itself into an early recognition of the underlying factors, and the application of such remedies as stimulate the production of antitoxic substances by the tissue cells, the destruction of the poisons by the liver and their elimination by the various emunctories.

Acute Septic Inflammations of the Mouth and Throat.

Dr. J. A. Ellegood, Wilmington, referred to the gravity and high mortality of many cases of acute septic processes occurring in this region, and stated that from an etiologic and pathologic standpoint they are identical with erysipelas as occurring in other parts of the body. The clinical character is peculiar on account of their primary occurrence in the mucous membrane, the peculiar and complex anatomic arrangement of the parts involved, and the proximity to the larynx. The clinical features of some of the more severe forms are described. Ludwig's angina is referred to as being an inflammation of the same nature as a septic laryngitis or pharyngitis, the distinction being more of an anatomic than of an etiologic character. Acute inflammation may be followed by ulceration. Milder forms occur, varying in degree from the slightest ulceration to those displaying the greatest malignancy. On account of the anatomic structure of the parts, the tonsils most frequently are the seat of primary infection, and most cases begin as an apparently ordinary form of tonsillitis. Although a great variety of micro-organisms are capable of exciting or taking part in septic processes, the streptococci and staphylococci are regarded as the chief offending agents, at least, in the milder cases. Among the predisposing causes, attention is called to the probable influence of autointoxication, and to the possible good results that may be attained by means of intravenous injection of saline solutions, both with and without general blood-letting. Serum therapy is discussed at length. In case a bacteriologic diagnosis is impossible, the use of an antistreptococcal or of a polyvalent serum is advised. Particular stress is laid on prophylaxis.

Thrombosis of the Popliteal Artery Complicating Typhoid.

Dr. William Chandler Pierce, Wilmington, cited the case of a man, age 38 years, who had been under the treatment of a physician for two weeks for typhoid fever. Examination confirmed this diagnosis and also revealed marked discoloration of the left leg from the knee down; the leg, foot, toes and skin were very dry, smooth and like leather to the touch, the discoloration ranging from black on the toes to dark-brown and gray on the foot, and shades of brown and gray on the leg. The leg emitted a distinct odor. On inquiry it was elicited that four days previously the patient had suffered from pain in the back of the leg, and that at this time the leg began to change color. There was no pulse in the popliteal artery and no glycosuria. A diagnosis was made of dry gangrene following thrombosis of the popliteal artery complicating typhoid. Amputation of the lower third of the thigh was advised when the patient's condition should improve sufficiently to admit of it. The patient died shortly afterward in convulsions.

Fracture of Patella.

Dr. James A. Draper, Wilmington, cited the case of a man who had fallen from a telephone pole, sustaining a compound fracture of the thigh about midway, and a fracture of the patella. The fracture of the thigh was treated by wiring, and there is no appreciable shortening. In the treatment of fracture of the patella, he had applied a ring pessary and posterior splint, which has proven very satisfactory.

Discussion on Autointoxication.

The discussion on the papers was opened by **Dr. H. Brooker Mills**, Philadelphia, who called attention to the fact that, while Dr. Robin's paper primarily related to autointoxication, the others also bore on this subject, as the patient in the case reported by Dr. Pierce clearly died from a general poisoning or autointoxication resulting from a local origin, and many cases of infection of the mouth cause a general intoxication. He reported the case of a Civil War veteran, who had been treated by a number of prominent physicians, for 237 carbuncles, when finally autointoxication was discovered and treated, and the man cured. He also referred to two cases of epilepsy, who had had attacks for years, at least every two weeks, in which he had made the diagnosis of autointoxication of intestinal origin, and originated treatment along the usual lines therefor, including intestinal enemata, with the result that the disease is now entirely cured, apparently neither patient having had an attack within the past two years. He called attention to the necessity for a thorough movement of the bowels daily, and carefully distinguished this term from a daily movement, and, in the detection of these conditions, urinalyses and the determination of the amount of indican, acetone and urea are of the utmost importance. The fecal examination, he felt, should not be omitted, as, while it might be somewhat difficult and require considerable apparatus and time, the results would more than compensate the physician therefor. The use of large doses of purgatives was not recommended; calomel in doses of 1/12 of a grain every hour for twelve hours, followed next morning by phosphate of sodium, a teaspoonful in a glass of hot water one hour before breakfast was cited as a valuable remedy, and, if this does not sufficiently open the bowels, colonic irrigation by means of a long, soft rubber rectal tube should be employed. He called attention to the important part which the skin played in the function of elimination, and urged the stimulation of its activity by drinking large quantities of water between meals. Venesection was considered a mode of relief, but was not felt to be practicable in many, especially the very anemic cases. In conclusion, he called attention to the facts (1) that autointoxication is much more common than it is realized, and (2) that many diseases, local and constitutional, which seem to be difficult of diagnosis are, in reality, due to this condition, and urged the correction thereof, not by large doses of powerful drugs, but simply by emptying the colon by means of the bladder, bowels and kidneys and by careful dietetic and hygienic regulations.

Dr. J. A. Ellegood, Wilmington, felt that Dr. Mills did not make sufficiently clear the difference between autointoxication and ptomain poisoning, the former being produced by chemical leucomains arising from within the body caused by the disturbance of the normal metabolic changes, while the latter are caused entirely by extrinsic substances, and that there was a danger of attributing too many conditions to autointoxication.

Dr. Swithin Chandler, Philadelphia, stated that autointoxication arose solely from causes arising within the body, and not by the absorption of germs introduced from without, and that, while he believed it was important to lay stress on the proper evacuation of the colon, this would have no effect on the conditions produced by germs from without the body, etc. Attention should be given, he stated, to the secondary, as well as the elementary effect of any article—for instance, food that produces uric acid should not be given, not so much for the fact that it produces uric acid as because of the changes that will take place between the proteids and uric acid to make up the by-products and cause autointoxication, and the kidneys should be observed, as much because of the irritation produced as because of their function of elimination. The cases reported by Drs. Ellegood and Pierce, he felt, were cases of toxemia, but not autointoxication.

Dr. Willard Springer, Wilmington, called attention to the fact that the infection in Dr. Pierce's case arose within the body, and that consequently it was an autointoxication.

Dr. Cleaver stated that in cases of diabetes and other similar conditions which result in blocking up the secretion of the urine there is no doubt that marked toxemia does occur, and cited such authorities as von Jaksch and Nothnagel in support of this position. While he did not feel that flushing of the colon would relieve all cases of diabetes, he believed there was no doubt that some pronounced toxemias were cured thereby.

Dr. A. Robin, Wilmington, felt that many of the cases of strict infection were complicated by autointoxication and secondary toxemia, as in the case of gangrene, the secondary infection occurring therein was produced by the formation of putrefaction from the gangrene, which is just as much autointoxication as anything else. The same is true in a case of secondary infection in a case of typhoid, the typhoid bacillus is the primary infection, but autointoxication may arise from other matters generated within the body by reason of this specific germ. He called attention to the fact that he believed the reason the autointoxication was not manifest in all cases was due to the fact that there were certain other cells in the body producing antitoxins, which neutralize the toxins produced by the liver and other organs, and called attention to the necessity for stimulating the function of the antitoxin cells.

Dr. H. Brooker Mills, Philadelphia, stated that, while he did not believe all cases of diabetes or epilepsy could be cured by colonic irrigation, yet, if they could be proved to be due to reflex or other irritation having its origin in the gastrointestinal tract, he believed this to be the most important agency known to medicine for the relief thereof. He felt that in any cause in which the poison arose within the body it must be classed as autointoxication, and believed that the cases of both Dr. Pierce and Dr. Ellegood could be properly classed under this class.

The next annual meeting is to be held in Wilmington Oct. 9, 1906.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Oct. 3, 1905.

The President, Dr. Arthur P. Hitchens, in the Chair.

Ventrosuspension of Uterus.

Dr. Swithin Chandler directed particular attention to the importance of absolute certainty in diagnosis, and stated that fixation should be undertaken only by a surgeon competent to perform the most difficult abdominal operation. He reviewed the various operations employed, including the intraperitoneal shortening of the round ligaments, the Alexander operation, and considered the suspension of the uterus by suturing the fundus uteri to the peritoneum to be the ideal procedure, but did not believe in the use of the pessary. He also urged careful technic, and particularly that no blood be left in the abdominal incision.

DISCUSSION.

Dr. M. P. Warmuth felt that the fixation operation was the one that should be done in the majority of cases, at the same time repairing any lacerations of the pelvic floor and removing endometritis, if present, by curettage. He reported several cases of ventrofixation which had subsequently caused complications, which are particularly likely to occur during subsequent pregnancies.

Dr. Luther C. Peter felt that if the statistics of the operator were supplemented by those of the general practitioner they would probably show up somewhat different, and referred to the case of a multipara, aged 30, in whom an Alexander operation had been done with absolutely no results.

Etiology and Treatment of Constipation.

Dr. Herman A. Bray stated that constipation is more frequent in females than in males and in adults than in children. One of the prominent causes in women is uterine trouble, and among the results are rectal disease, anal fissure, ulceration of the rectum and sigmoid flexure, proctitis and periproctitis. Headache, loss of memory and inability to concentrate thoughts are prominent symptoms. The causes of the condition are mechanical obstruction; defective peristaltic action; deficient intestinal secretion; deficiency of liquid; nervous instability, etc. The underlying cause should be diagnosed and treatment directed to the removal thereof. Stricture of the sphincter ani he believed to be one of the chief causes, and this should be remedied by dilation under local or general anesthesia. The treatment he outlined as follows: Light diet; plenty of fruit, such as oranges, figs, apples, stewed prunes; drinking a tumblerful of water on rising in the morning; regular hour for defecation; avoidance of sedentary life; purgatives should not be given, and only medication of the mildest possible kind. The injection of olive oil, use of electricity and massage, in conjunction with hygienic and dietetic measures, are of value. The exact treatment must be decided for each individual case.

DISCUSSION.

Dr. Swithin Chandler emphasized the importance of paying strict attention to the diet, and called attention to the fact that some of the cereals, if taken repeatedly, have a tendency to cause the condition, and urged as a routine measure the thorough examination of the patient to discover the causative element.

Dr. Wendell Reber referred to the fact that many cases of constipation show a peculiar condition of the optic nerve, with intense fullness of the lymph tubes, as indicating defective elimination, and urged as important factors in the treatment a cold sponge bath in the morning and hygienic and dietetic regulations.

Dr. Carle Lee Felt referred to the case of a girl suffering from constipation who had been treated for a long time by drugs, electricity, etc., with absolutely no effect, when strychnia was pushed to tolerance, which quickly cured her. When she returned again, two or three years later, the same drug quickly gave relief.

Dr. Luther C. Peter stated that a great many nervous conditions can be traced to constipation as a causative factor. He considers strychnia as one of the best drugs for combating the condition.

Dr. Albert Bernheim believed that the constant use of purgatives was detrimental, and that many of the patients who report to the physician that they have a daily bowel movement in reality have feces impacted around the edge of the colon, while the center might be in a condition which would cause diarrhea. The mode of dress, particularly in women, has much to do with the production of the condition; horseback riding has been proved to be a causative factor. Enema may be given for a long time without any deleterious results, preferably by means of a soft rubber tube. Glycerin, eserin, massage, etc., are of value.

Dr. Lewis S. Somers recommended that the patient be instructed to spend a longer time at stool, during which his whole mind should be on this act, no books or papers, etc., being taken to the closet by the patient. He referred to the work of Dr. Stucky, of Kentucky, who has been treating cases of pharyngitis by washing out the bowel several times a week, followed by injections of half a pint of olive oil, and claims to be securing good results.

Dr. Bray stated that he believed the condition of the eyegrounds to be an important diagnostic factor in these cases, and that frequently headaches result from reabsorption of the liquid part of the feces. Constant use of drugs and purgatives is harmful, as is also the constant employment of enemata, as this causes an overdistension of the bowel. He urged thorough digital examination in every case.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Earache.

Lake, in the *Clinical Journal*, in the treatment of this condition mentions among local measures a combination of the so-called oil of hyoscyamus with a little of the tincture of opium; he advises the application of opium salve over the mastoid and along the canal, and equal parts of olive oil and chloroform dropped in the ear. Carbolized glycerin, he states, is useful, as also douches containing opium, morphin or cocain. Of all these remedies, few equal and none excel the local application of chloroform vapor. Especially in the case of children these remedies must be carefully considered and it is often advisable to dispense with opium, which is badly borne by children, and to use hyoscyamus, belladonna or carbolic acid. Other therapeutic aids in this condition are hot compresses, hot irrigations and counterirritants.

Considering the treatment in the relation of the causes of earache, the author recommends a free incision of the drum. This gives the most speedy relief when the inflammation is confined to the middle ear. If the inflammation is extended beyond the middle ear the incision will only partly relieve the symptoms; at the same time leeches should be applied over the mastoid fairly close to the auricle, and hot irrigations and hot compresses should be applied, frequently repeated. The author believes that in the chronic suppurative otitis media the radical mastoid operation gives very satisfactory results. In case of furunculosis of the meatus he states that if pus has escaped from a furuncle before the physician sees the patient, and the pain is subsiding rapidly, all the treatment necessary is a thorough antiseptic cleansing of the meatus, preferably with an alkaline solution, and the use of peroxid of hydrogen, or a 10 per cent. solution carbolized glycerin. If, however, the physician sees the patient before relief from pain has been obtained, not only should he make an incision, passing completely through the center of the furuncle, but the incision should be carried down to the cone, the contents of the furuncle should be removed by a small scoop and the cavity packed.

Infantile Convulsions.

Cautley, in the *Clinical Journal*, gives the following treatment for this condition:

When summoned to a child in a convulsion the physician should take with him chloroform, a chloral hydrate solution of known strength, amyl nitrite, solution of morphin, and a hypodermic syringe. [Morphin and chloral hydrate must be used with extreme caution in children.—Ed.] Probably the attack will be over by the time he arrives, or, if not, the child will have been undressed and given the usual hot bath, with or without mustard in it. As soon as the attack starts the child should be laid down, with the head a little raised, and the clothes loosened or removed. All unnecessary disturbance must be avoided and the child kept quiet. A bath of from 95 to 100 F. may be given, with a view to relieving the congestion of the brain, or a dry mustard pack may be employed as less disturbing. After the child has been in the bath for five minutes it must be wrapped up in hot blankets. The bath is most useful in cases due to colic and is contraindicated in convulsions due to syncope or collapse of the lung. It does not interfere with other measures of treatment. While in the bath and after, cold affusions should be applied to the head by cloths wrung out in cold water or by an ice cap. The lower bowel can be washed out by salt solution, one dram to half-pint of warm water, or sodium sulphate in the proportion of half an ounce to half a pint for an older child; or a glycerin enema may be given. After the bowels have acted, a small rectal injection of chloral hydrate should be given, grains 3 to 10, according to the age of the child; potassium bromid may be combined with the chloral. The rectal injection should not be of more than two ounces bulk for a child aged 1 year, and the buttocks must be held together for a few minutes after injection. [The child must be carefully watched after the administration of chloral or the bromid, and these drugs should be used with great caution.—Ed.] Should there be evidence of the existence of unsuitable food in the stomach, vomiting may be induced by tickling the fauces with a feather or by ipecacuanha wine between the spasms. As a rule, irritant food has passed through the pylorus before the attack is induced. As soon as the child can swallow a dose of calomel should be given. It empties the intestinal tract and relieves cerebral congestion. Emetics should be avoided at this stage.

As soon as the secretion of urine is abundant it is evident that the kidneys are working efficiently and that active treatment can be discontinued. Abundant urination may be looked on as a critical phenomenon announcing the speedy termination of the convulsion. After the attack the child must be kept quiet for a few days on a light diet, and the bowels carefully regulated. During sleep the room must be kept well ventilated, the feet warm and the head raised. Borax, salts of zinc, belladonna and valerianate of zinc may be of use in the treatment.

When there is definite disease the treatment is naturally that appropriate to the disease. All sources of reflex irritation should be attended to, such as adenoids, enlarged tonsils, worms, genital irritation, and ear and eye troubles. The general health and diet should be most carefully watched and tended. The drugs most useful in prevention of infantile convulsions are cod liver oil, malt and iron. In treatment of epilepsy in older children bromids should be given for at least two years, and may be combined with salt starvation. The addition of opium is sometimes useful. Borax, belladonna, the salts of zinc and the valerianates are the next most useful drugs.

In all cases careful attention must be paid to the intestinal tract; constipation remedies and intestinal antiseptics are to be given if necessary. The diet should be plain and unseasoned and should contain little meat. As a rule the regularity of school life is beneficial, but it may be injurious from the effects of teasing by other children, excitement, and over mental pressure for examination. On the whole, it is advisable that a child with epileptic fits should, if possible, be brought up at home in the country, under the care of an intelligent tutor, and should live the life of a healthy animal and learn to earn a living at some outdooor occupation involving more or less physical labor.

Thompson, in *International Clinics*, discusses the treatment from a causative standpoint, first considering the treatment of the child while in the attack. The child should be placed in a warm bath, with or without mustard in it. If mustard is used, about two tablespoonfuls to the gallon is recommended. The child may be placed in a mustard pack and kept there from ten to fifteen minutes. If, however, the fit is prolonged for more than five minutes, or recurs at short intervals, it is best to administer chloroform to control the convulsive movements. Chloral hydrate is another effectual remedy, but as the infant is unable at the time to swallow, it must be administered either hypodermically or injected into the bowels through a rubber catheter.

In the new-born infant with convulsions resulting from injury received during birth sedatives are of little value. The child should be kept as quiet and warm as possible and attention given to its nourishment.

For convulsions in the dyspeptic infant sedatives are of small service. The bowels should be cleansed with a dose of calomel and castor oil and the diet should be modified. Attention should be given to the breast milk. When breast milk is not possible special care should be used in the preparation of a substitute.

In so-called idiopathic convulsions in young babies, expectant treatment, bromids and treatment of the alimentary canal are a waste of time. Chloral should be used (with great caution), the dose varying with the age of the child. This to be continued until the attacks have entirely ceased for from six to eight hours or more, and if not speedily effectual, the dose can be increased until the child begins to get too drowsy to swallow his milk. When the convulsions have entirely ceased for some time the intervals between the doses is gradually lengthened. Usually within three or four days the medicine can be discontinued without any return of the convulsions.

In "teething fits" or "rickety fits" the diet must be regulated on antirachitic lines, and cod liver oil should be given, with or without phosphorus. It is important to see that the child has plenty of fresh air and cold douches given once or twice daily. For these the infant is placed in an inch or so of warm water in front of a fire, and a large jugful of cold water (from 60 to 70 F.), is promptly poured over the shoulders and back. The child is then taken out and rubbed until dry and warm. Under this regimen the child's health improves and all tendency to convulsions soon disappears.

In convulsions caused by serious cerebral defects the result of treatment is very discouraging. Bromids may sometimes be of use. Generally, however, when given in doses large enough to affect the attacks, they interfere considerably with the child's general health. Anything which produces a distinct improvement in the child's general condition, however, may diminish the number and severity of the attacks. Thus a change to the country or the timely administration of a tonic may diminish or stop them for many weeks. In some few cases thyroid substance has a good effect.

Medicolegal

Advertising Monthly Regulators Forbidden.

Chapter 167 of the Public Acts of Connecticut of 1905 amends Section 1157 of the General Statutes, which prescribes a penalty for encouraging the commission of abortion, by inserting "or who shall advertise any so-called monthly regulator for women," shall be fined not more than $500.

Wood Alcohol to be Labeled "Poison."

Chapter 75 of the Public Acts of Connecticut of 1905 amends Section 4734 of the General Statutes of that state by adding "wood or methylic alcohol under any name or in any mixture" to list of drugs which said section requires that the bottle, box, or wrapper containing same when sold shall be marked "poison," except when for use in manufactures or the arts, etc.

May Establish a Bacteriologic Laboratory.

Chapter 162 of the Public Acts of Connecticut of 1905 provides that the state board of health may establish and control a bacteriologic laboratory where examination of supposed morbid tissues for the diagnosis of infectious diseases shall be made, free of expense, on the application of registered physicians or health officers, and may provide necessary buildings and apparatus, employ bacteriologists and assistants, and do all things necessary for the proper conduct of such a laboratory.

"Heart Failure" Not Sufficient as Cause of Death.

Chapter 21 of the Public Acts of Connecticut of 1905 amends Section 1862 of the General Statutes by inserting therein the words, "a certificate of death giving heart failure, paralysis of heart, cardiac incompetence, cardiac exhaustion, heart weakness, collapse of heart, cardiac syncope, cardiac paralysis, or any like term having the same meaning as heart failure, shall not be deemed sufficient on which to issue a burial or removal permit, and such certificate must be returned to the physician who made it for the proper correction and definition."

No Preservative or Coloring Matter for Meats.

No. 46 of the Laws of Pennsylvania of 1905 provides that if any person, firm or corporate body shall, by himself, herself or themselves, or by his, her or their or its agents or servants, sell, ship, consign, offer for sale, expose for sale, or have in possession with intent to sell, as fresh, any meat, poultry, game or shell fish which contains any substance, article or ingredient possessing a preservative character or action, or which contains any coal-tar dye, or any other substance or ingredient possessing a coloring character or action, shall be deemed guilty of a misdemeanor, etc.; provided, that nothing in this section shall prohibit the use of ice as a preservative, or proper refrigeration.

Regulation of Practice of Optometry.

Chapter 96 of the Laws of New Mexico of 1905 is entitled "An act to regulate the practice of optometry and for the appointment for the board of examiners in the matter of said regulation." It defines the practice of optometry as the employment of subjective and objective mechanical means to determine the accommodative and refractive states of the eye and the scope of its functions in general. It provides that every person, before beginning the practice of optometry in this territory, after the passage of this act, shall pass an examination before said board; examination shall be confined to such knowledge as is essential to the practice of optometry. But nothing in this act shall be construed to apply to physicians and surgeons authorized to practice under the laws of the territory of New Mexico.

May Admit Holders of Certificates from Other States.

On page 212 of the Laws of Missouri of 1905 is an act which amends Section 3 of the act regulating the practice of medicine by adding thereto the words: "And it is further provided that the said state board of health may at their discretion admit without examination legally qualified practitioners of medicine who hold certificates to practice medicine in any state or territory in the United States, or the District of Columbia, with equal requirements to the state of Missouri (and that extend like privileges to legally qualified practitioners from this state), on the applicant paying a fee of $25." The words here inclosed in parenthesis are, however, omitted from the statement of the proposed amendment in the first part of the amendatory act.

Cocain to be Sold Only on Prescription.

On page 145 of the Laws of Missouri of 1905 is an act which provides, under penalty, that it shall not be lawful for any druggist or other person to retail, or sell, or to give away any cocain, hydrochlorate, or other salt of or any compound of cocain, or preparation containing cocain, or any salts of or compound thereof, except on the written prescription of a licensed physician or licensed dentist, licensed under the laws of the state, which prescription shall only be filled once; provided, that this shall not apply to sales in the usual quantities at wholesale by any manufacturer or wholesale dealer when such manufacturer or wholesale dealer shall have affixed to the box, bottle or package containing such cocain, hydrochlorate or other salt or compound of cocain or preparation containing cocain, a label specifically setting forth the proportion of cocain contained in any preparation.

Restricts Sale of Cocain, Eucain and Their Salts.

Chapter 127 of the Public Acts of Connecticut of 1905 provides that it shall be unlawful for any person, firm, or corporation to sell, furnish, or give away any cocain, salts of cocain, eucain or its salts, or any preparation containing any cocain, or salts of cocain, or eucain or its salts, except on the original written order or prescription of a lawfully authorized practitioner of medicine or veterinary medicine, which order or prescription shall be dated, and shall contain the name of the person for whom prescribed, or, if ordered by a practitioner of veterinary medicine, shall state the kind of animal for which ordered, and shall be signed by the person giving the prescription or order; and such written order or prescription shall be permanently retained on file by the person, firm, or corporation who shall compound or dispense the articles ordered or prescribed, and it shall not be recompounded or dispensed a second time except on the written order of the original prescriber; provided, however, that the provisions of this act shall not apply to sales at wholesale by jobbers, wholesalers, and manufacturers to retail druggists, nor to sales at retail by retail druggists to regular practitioners of medicine, dentistry, or veterinary medicine, nor to sales to hospitals, colleges, or scientific or public institutions.

Sanitarium for Treating Incipient Tuberculosis.

On pages 292-7 of the Laws of Missouri of 1905 is an act which provides for the establishment, as soon as practicable, of an institution for the treatment of incipient pulmonary tuberculosis, to be located in some suitable portion of the state, and to be known as the Missouri State Sanitarium for the treatment of pulmonary tuberculosis in its earlier stages, or, as stated in another section, to be known as "state sanitarium for the treatment of incipient pulmonary tuberculosis." Fifty thousand dollars is appropriated for this purpose. There must be not less than 160 acres of good land, which shall have an elevation of at least 1,000 feet above sea level. After this, special regard shall be had, first of all, to salubrity of location. Another point to be considered is convenience to pure and wholesome water. Some of the buildings shall be for a hospital, and others for cottage sanitarium purposes. Said buildings shall be constructed of substantial materials, the walls being of brick or stone, the interior subdivisions to conform, as near as may be, to the most modern improvements, having reference to the comfort and convenience of the inmates therein; they shall be as near fireproof as practicable, with partitions and fire walls between the wards; also such facilities for egress as will insure safety in case of fire. There shall be a board of managers, to consist of five persons, two of whom at least shall be practicing physicians of good repute, and all to be appointed by the governor, subject to the confirmation of the senate.

Emergency Fund Provisions for Epidemics and Disasters.

No. 219 of the Laws of Pennsylvania of 1905 appropriates $50,000 for the purpose of creating an emergency fund, to be used, as occasion may require, by the state board of health in the suppression of epidemics, prevention of disease, and protection of human life in times of epidemic disease or of disaster threatening disease, beyond the ability of the local authorities to check or relieve. This money shall be held in the treasury of the commonwealth, and whenever the secretary of the state board of health shall find that the public health is threatened, either by epidemic or as a result of great disaster, to such an extent that the local authorities are unable to meet the emergency, he shall prepare a statement to that effect, rehearsing all the facts in the case, and the reason for considering that state aid is needed, and to what amount, and transmit the same to the governor. If the statement and the reasons therein set forth shall meet with the approval of the governor, he shall certify and file the statement and certificate of approval in the office of the auditor general, who shall then draw his warrant on the state treasurer for the amount approved by the governor, and place the same in the hands of the treasurer of the state board of health, to be used for the purpose set forth in the statement approved as aforesaid, and for no other purpose. If, after the said epidemic shall have been suppressed, or the sickness or danger averted, there shall still be a balance of the amount drawn left in the hands of the treasurer of the state board of health, he shall, without delay, return the same to the state treasurer, and it shall become part of the said emergency fund. He shall also file with the auditor general a specifically itemized statement, made under oath, of the expenditures of said moneys, as soon as possible.

6 Deflection of the Nasal Septum in Children. A. A. Bliss, Philadelphia.

1. Examination of Leucocytes as Diagnostic Aid.—Brown reviews our knowledge of the variations in the white blood cells in health and in disease, and the aid that may be derived from their study. He says that a thorough appreciation of the exact significance of leucocytosis will not be possible until we have definitely determined the mode of origin of the various forms of the white blood cells and their relationship to each other. Nevertheless, study of these cells in the various diseases and pathologic conditions has demonstrated beyond a doubt that their determination is of real practical help in the diagnosis and prognosis of disease. There are only a few diseases in which an absolute diagnosis can be made from the blood examination alone; in the vast majority of cases the condition of the leucocytes aids in making the diagnosis; in many cases, however, it is an important point without which the diagnosis would be even more incomplete than, of necessity, it is often forced to be. Thus, the study of the leucocytes has rendered possible the diagnosis of a certain number of diseases, as the leukemias and trichinosis, besides rendering marked assistance in the diagnosis of others, as tuberculosis, typhoid fever, pneumonia and various inflammatory and suppurative conditions. It tells much in regard to the prognosis of all forms of infection and inflammation. It has aided in discriminating diseases presenting clinical pictures markedly alike, such as central pneumonia and typhoid fever, appendicitis and conditions simulating it but of entirely different origin, peritonitis and gastrointestinal autointoxication, lymphatic leukemia and Hodgkins' disease, myelogenous leukemia and Banti's disease, measles and scarlet fever, etc. It has provided the surgeon and gynecologist with a ready means of determining, in the first place, whether or not he is dealing with inflammatory or suppurative processes; in the second place, whether the process is diminishing or increasing, while in the third place, it tells him much, if he can but read the figures aright, regarding the prognosis of his cases. Leucocyte counting, says Brown, has not and never will reach the point at which it and it alone will furnish us with an absolutely correct diagnosis and prognosis, but in the past it has been a great, and it will be in the future an even greater help to the physician and surgeon who value correctly its possibility and its limitations.

2. Dilation and Curettement for Dysmenorrhea.—Holden analyzes reports received from 95 patients at periods varying from one to twelve years after dilation and curettement for dysmenorrhea. He finds that 40 per cent. were entirely or very greatly relieved for at least one year with 7 per cent. out of this 40 per cent. having a recurrence of the dysmenorrhea after one year or more; 30 per cent. had no relief at all, while the remaining 30 per cent. had but slight relief or relief for a few months only. Marked maldevelopment of the pelvic organs was present in 20 cases and in only 25 per cent. of these were the patients relieved. From a study of the character of the pains Holden concludes that the prognosis for relief after dilation and curettement is better when the pains are sharp, begin the day of the flow or the day before, and last but a day or two. The prognosis is bad when pains are dull, begin several days before the flow, and last for several days or throughout the flow. Dysmenorrhea may be caused by lurking pelvic inflammatory disease which is not recognized at pelvic examination under ether. In these cases dilation and especially curettement may make the symptoms much worse. Neurasthenia, anemia or malnutrition are frequently present. In some cases such conditions are the cause of the dysmenorrhea. To get good results from the operation these conditions must also be cured. In 61 of the cases a microscopic examination of the curettings was made. Chronic endometritis in such relation as to be a possible cause of the dysmenorrhea was present in but 4 cases, hence Holden concludes that chronic endometritis is an infrequent cause of dysmenorrhea. As but 3 out of 20 sterile married women of this series, in the child-bearing period, conceived within a year after the operation, the value of dilation and curettement in relieving sterility does not seem great. In general the procedure should be limited to cases in which there are no gross pathologic lesions, such as retrodisplacements, inflammatory disease of adnexa, or myomas, to account for the dysmenorrhea.

3. Mercury in Syphilis.—Lerch explains why mercury is more effective when given by inunction. He urges that in tabes and paresis antiluetic treatment should be tried, as it is often impossible to make a positive diagnosis. A certain an-

alogy between syphilis and tuberculosis has led him to give inunctions of iodoform in tuberculosis. He has had good results.

4. **Intranasal Drainage of Frontal Sinus.**—Ingals describes a method which, he says, by reason of its simplicity, thoroughness, and freedom from complications, is an improvement on other methods now in use. In five illustrative cases he explains in detail the various steps of the new operation and the instruments employed. He claims that this operation for intranasal drainage of the frontal sinus can be easily, quickly and safely done in those cases in which it is possible to introduce a probe through the nasofrontal canal. It established free drainage and furnishes a means whereby the patient, without aid, may wash out and medicate the sinus as desired. A hemorrhage can not result from this operation that could not be checked by the packing, except in hemophilia. Perforation of the cerebral wall of the sinus is impossible. The patient's consent can be obtained for this operation much more easily than for an opening through the eyebrow, and thus many cases may be cured in their incipiency that would otherwise prove very tedious and would ultimately demand a more serious operation. This operation would probably prove curative in nearly all cases of acute suppurative frontal sinusitis. It will prove curative in a large percentage of chronic cases. It will be a valuable preliminary to the radical operation in practically all cases. From the curative results in two out of three chronic cases and from the marked benefit in the third, it would appear that the advantages of this operation are so marked that it should be recommended in preference to the external operation in practically all cases, for even if a cure should not result, the conditions will be improved for a radical operation.

7. **Treatment of General Peritonitis.**—McCosh urges that the treatment of this condition should vary according to the etiology, duration and virulence of the disease, and also according to the resisting power of the patient. He questions the advisability of immediate operation in all cases, but he does not recommend non-operative treatment even in the majority of cases. The surgeon should always consider whether operation will give the patient the best chance for recovery. Ten years ago McCosh says he was in the habit of operating in 80 or 90 per cent. of all these cases. Now he operates in only about 50 per cent. The most important features of operation for general peritonitis are: 1, Rapidity; 2, gentleness; 3, removal of the cause; 4, postoperative elevation of the trunk and head, with corresponding depression of the pelvis. General anesthesia, as a rule, is preferable to any method of local anesthesia. Chloroform is frequently to be preferred to ether, though a mixture on an open mask is often the most advantageous. As a rule, when the cause is known, the incision should be made over the spot where lies the exciting lesion. In cases of doubt immediate incision is best. Wherever situated, a length of from 8 to 10 cm. is generally sufficient. If not, the incision can be extended during the progress of the operation. An incision of from 12 to 20 cm. does not seem to offer any advantages, and if recovery follows, is apt to result in discomfort to the patient. As a rule, an intermuscular incision is not advisable, though in lax abdomens either the McBurney or Kümmerer incision is sometimes sufficient. The incision along the outer edge of the right rectus muscle is generally the most convenient. The cause of the peritonitis is immediately sought and brought into view. At the same time it is determined whether or not the peritonitis is general. If general, irrigation through a tube is at once begun. Normal salt solution at a temperature of 110 F. is employed, through a hose of good size, and with considerable force. The rubber hose itself may be inserted, or there may be attached a long glass irrigating tube or a double current glass tube, for ingress and egress of the fluid. The irrigation is begun in the flanks and systematically carried to different parts of the abdominal cavity, terminating with a thorough washing out of the pelvis. The hand of the operator, covered *invariably* by a rubber glove, by gentle manipulation, helps the washing process. If the intestines have emerged from the abdominal cavity, they are carefully protected by hot towels, and flooded with hot saline solution. Generally, into the upper part of the small intestine there is injected through a large hypodermic needle 30 gm. of a saturated solution of magnesium sulphate, the puncture being afterward closed by a Lembert suture. When the peritoneal contents have been replaced, nothing remains but the closure of the wound and drainage. This is effected by the employment of one or two drains of small diameter, the remainder of the wound being closed. One of these drains generally passes into the pelvis, and often another into the loin. This latter may emerge through a stab wound made posteriorly. The "cigarette drain" is McCosh's favorite. It consists of a thin strip of sterile gauze, around which is loosely wrapped a layer or two of thin rubber tissue. In place of the cigarette drain, especially if the pus be thick, a fenestrated rubber tube is sometimes employed. He never employs for purposes of drainage unprotected gauze strips or masses of packing. A strip of gauze, carried through a glass tube into the pelvis, however, is occasionally used. For the emergence of these drains comfortable spaces are left in the wound unsutured, or the sutures may be inserted for future use, but left untied. Often while the operation is in progress, an intravenous saline infusion is given by an assistant. The smallest possible amount of anesthetic is administered. To reduce tympanites McCosh administers .002 mg. physistigmin salicylate hypodermically. A small hypodermic injection of morphin is usually administered at the close of the operation. The postoperative treatment is of importance. The patient is placed in Fowler's position for a week, the thighs being flexed over one or two pillows. Starvation is absolute until abdominal distension is diminished and until vomiting ceases. Gastric lavage is frequently given before the patient leaves the operating table, and is often continued at intervals until vomiting ceases. Drainage remains as established for thirty-six to forty-eight hours, and then its removal is begun cautiously and gradually.

9. **Digestibility of Evaporated Cream.**—Mojonnier's investigations lead to the following conclusions: 1. The protein in evaporated cream digests a little more rapidly when treated with artificial gastric juice than does that of raw, Pasteurized or boiled milk. 2. The protein in evaporated cream is almost entirely soluble in artificial gastric juice. Its total digestibility by this method compares very favorably with that of raw, Pasteurized and boiled milk. The small difference found was in favor of the evaporated cream. 3. By means of natural digestion experiments with a child and with a man, the child was found to digest evaporated cream a little more completely than did the man. It was found that in the case of the child that only 3.31 per cent. and in the case of the man only 6.81 per cent. of the entire solid matter of the food remained undigested. 4. The total digestibility of the protein in evaporated cream, after making correction for the metabolic products in the feces, in the case of the child was found to be 98.48 per cent., or very nearly what was found by means of artificial gastric juice, namely, 98.89 per cent. With the man it was found to be 93.10 per cent. 5. The butter fat and milk sugar were both very completely digested and assimilated by two subjects. The child digested 98.80 per cent. of the fat and 97.78 per cent. of the sugar. The man digested 95.84 per cent. of the fat and 96.85 per cent. of the sugar. 6. The child digested nearly 18 per cent. more of the mineral matter than did the man. This accords with the accepted theory that a child requires more mineral matter in proportion to its body weight than does an adult because its bones are growing and developing. 7. The total energy or fuel value of evaporated cream is almost entirely available to the body. The child used 97.25 per cent. and the man 94.59 per cent. of the total energy contained in the evaporated cream which they used. 8. The health of both subjects was

normal during the experiments. The child gained in weight, an average of about one pound a week and relished its diet. The man lost in body weight, but gained in protein to the amount of nearly one-third ounce of protein a day. 9. Evaporated cream, like other forms of pure milk, is an economical article of diet because its nutrients are practically all available to the needs of the body.

12. **Extravisceral Rubber Ligature in Gastroenterostomy.**—Some time ago Coffey described an operation (THE JOURNAL, Jan. 2, 1905, page 72), of entero-enterostomy in which an extravisceral silk ligature was used. This method was very similar to the one described by Coffey in this paper, except that no cut was made and the silk ligature included all the coats. Coffey found that the method first described could not be well applied with the wall of the stomach because of its great thickness. The operation is now performed as follows: First, the incision is made both in the abdominal wall and in the mesocolon in exactly the same manner as if the short loop operation were to be done with clamps or the McGraw ligature. The stomach is pushed down through the mesocolon from above, by the hand of the operator or assistant, and held there. Second, a circular button is cut with a sharp knife down to the submucous connective tissue, great care and caution being exercised not to cut the submucous plexus of vessels. As the mucous membrane is approached, the muscular fibers, both in the wall of the stomach and in the button, contract, leaving quite a wide circular cut. The same thing is done with the intestine, except that the button is made oblong, parallel with the axis of the intestine, in order not to encroach too much on the lumen of the intestine, and also to avoid the larger vessels. Third, the button and mucous membrane are picked up gently with a wide forceps like a sponge holder, or, if preferred, with the fingers; a silk or linen thread is then laid across one side of the wound, one end being held by an assistant, the other lying loose. A rubber band of the size of No. 14 braided silk is cut in two, making of it a thread instead of a band. The mucous membrane is pulled out as far as possible, without tearing or injuring it, so that as big a bite as possible may be cut out. One end of the rubber string is held with a pair of forceps by an assistant, while the operator takes the other end, with or without forceps, and proceeds to wrap the rubber around the mucous membrane, including the thread, which is to tie the rubber. If the rubber is as small as it should be, ten or twenty turns should be made. The string is tied around all the rubber to prevent slipping. The suture is continued all the way around, and the last end is tied with the end left loose for this purpose at the starting point. One of the main advantages of this operation, says Coffey, is the fact that no opening is made into the intestine or stomach at the time of the operation, hence the danger of infection is minimized.

18 Case of Primary Lupus Vulgaris of the Oropharynx and Nasopharynx, Treated by X-rays. H. S. Birkett, Montreal.
19 *Acute Pancreatitis. J. G. Sheldon, Telluride, Colo.

13. **Antepartum Measurement of Fetal Head.**—Stone shows that the antepartum measurement of the fetal head is as feasible as is pelvimetry, and that these measurements afford a more precise method of estimating the course of labor in contracted pelves than any other now available. They are of the greatest value in the selection of the cases suitable for premature induction of labor, and in the determination of the best time for performing it. Stone's method of measurement is described as follows: "The patient is placed in the ordinary dorsal position for an abdominal examination, and the examiner, standing by the side and placing the lower end of the patient's body, first carefully palpates and makes out the position of the head. If it is already engaged in the pelvis, it will not be practicable to measure it, but in such cases it naturally is unnecessary. The occipital and frontal poles are then grasped between the two hands, and an assistant places from below the ends of the pelvimeter between the terminal phalanges of the middle and ring fingers of the examiner, pushing them firmly inward, as the examiner directs. It is essential that the ends of the pelvimeter go between these fingers, because in palpation one naturally places the middle or longest finger nearest the two poles from which the measurements are to be taken. If placed in front of the middle finger, the pelvimeter will slide forward and the measurement will be inaccurate. An assistant or nurse is necessary in order to obtain the best results, in order that the examiner's fingers may be entirely free accurately to locate the fetal parts." A table is given showing the results obtained before and after delivery in 41 patients measured in this way. In 28 instances the postpartum measurement of the occipitofrontal diameter agreed exactly with the measurements made through the abdominal walls before labor; in 11 there was an error of 0.25 cm.; in 2 of 0.50 cm. In another table the average amount to be deducted from each occipitofrontal diameter in order to obtain the biparietal diameter is given.

14. **Carcinoma of the Intestinal Tract.**—Tuttle discusses the symptoms and indications for treatment of cancer of the intestine, these varying according to the portion of the digestive tract occupied by the neoplasm. The various segments of the alimentary tract, in the order of frequency with which they are attacked by cancer are: stomach, rectum, sigmoid, cecum and ascending colon, transverse and descending colon, vermiform appendix, duodenum, ileum and jejunum. The prognosis of cancer of the intestinal tract without surgical interference is absolutely hopeless. The fact, however, that metastasis and glandular involvement are later in this area than in any other portion of the body renders surgical interference more hopeful here than elsewhere.

15. **Quick Curative Treatment of Gonorrhea.**—Lyons reports 400 cases treated by the method brought forward by him ten years ago. In 384 of these cases the disease was cured in six days, and in about 80 per cent. of this number in twenty-four hours. The method consists of injections into the urethra of a dram and a half of silver nitrate solution, at first in 4 per cent. strength, later in 2 per cent. and 1 per cent. strength. In most cases a single injection was sufficient. When a cure was not effected by three injections the treatment was discontinued. The method depends for its effect on the fact that early in the disease the gonococci lie entirely on the outer layer of epithelial cells, multiplying on them, destroying their vitality and causing them to exfoliate. At this stage the microscope shows many gonococci on the epithelial cells. There follows congestion, afflux of serum, exfoliation of all the epithelium until the subepithelial tissue is laid bare. There will now be in the discharge few epithelial cells and many pus cells. At this time the gonococci penetrate the connective tissue. As long as there appear under the microscope epithelial cells studded with gonococci, so long are the germs within reach of the germicide, and the case is amenable to quick treatment. The exfoliation of the epithelium caused by the silver nitrate only quickens the exfoliation produced by the disease and destroys the gonococci and does no harm.

17. **Diagnosis of Essential Anemias.**—Bridges discusses the differential points in the diagnosis of acute lymphatic leukemia, splenomyelogenous leukemia, splenic anemia with atrophic cirrhosis of the liver, and pernicious anemia, and reports one case of each disease.

19. **Acute Pancreatitis.**—Sheldon suggests the following points be made the subjects of discussion by writers on acute pancreatitis: 1. *The presence of glycerin in the urine*, which Cammidge and Robson claim is characteristic of pancreatic disease. 2. The infectious or mechanical nature of the process in the early stages of the disease. 3. The significance of the condition of the gall bladder. He has found it distended and very tense in three out of four patients with acute pancreatitis operated on or observed at autopsy, and did a cholecystotomy in a supposed instance of acute pancreatitis twelve hours after the onset of symptoms, the case terminating in recovery.

20 Relation of Animal Life to Human Diseases. T. Smith, Boston.
21 *Case of Pyloric Stenosis in an Infant. J. L. Morse and F. T. Murphy, Boston.
22 Separation of the Criminal Class from Other Insane in Institutions. C. A. Drew, Bridgewater, Mass.
23 Active Treatment of Muscular Rheumatism. B. B. Cates, Knoxville, Tenn.

21. **Pyloric Stenosis.**—In the case reported by Morse and Murphy, the vomiting began when the infant was two weeks old. Just before entering the hospital the infant passed a closed bib-pin about one inch long, which had been missing for about two weeks. The onset of the vomiting coincided pretty closely, therefore, with the disappearance of the pin. A diagnosis of chronic gastric indigestion was made, with stenosis of the pylorus to be considered. Various sorts of food were tried, and various plans of feeding were instituted, but without success, the vomiting continuing. There was nothing characteristic about the vomiting at any time. One week after admission of the patient to the hospital the lower border of the stomach was palpable just below the umbilicus, and at times visible peristalsis was made out, although it was not distinctly in waves. Two days later a mass the size of a small marble was felt about 1 cm. below and to the right of the umbilicus. The consistency and form of the mass were variable. The mass was freely movable but not tender. Operation was advised but refused. The only distinctive feature about the bowel movements was their meconium-like character. The operation, which was performed later, disclosed at the pylorus a bluish-red smooth and rounded tumor about the size and shape of a good sized dollar. The stomach was distended. Below the pylorus the entire intestinal tract was collapsed and contracted. The child died ten hours after the operation. The authors emphasize the following facts: 1. The symptoms may vary much from those of absolute pyloric obstruction, and they do not necessarily begin at birth. 2. The peculiar meconium-like character of the dejections may be of great diagnostic importance. 3. In complete or nearly complete pyloric obstruction, operation seems to offer the only hope of recovery. 4. The operation must be done before the infant has become reduced to the last degree of starvation, therefore an early diagnosis is imperative. 5. Pathologically, the condition is an entity.

29 *Three Vices of Blood Pressure. L. F. Bishop, New York.
30 Status of the Fetus in Utero. H. Hughes, Mankato, Minn.

26. **New Method of Exploring Abdomen.**—Ferguson points out the value of the various methods now in use of exploring the abdomen and calls attention to a new one devised by him. Through the incision for exposing the gall bladder and ducts it is his practice to see and feel all he can within a reasonable radius. It is not uncommon that appendicectomy can be performed through this incision without even extending it downward. In one instance he removed a stone in the right kidney through this incision. On the other hand, the bile ducts may be explored through the incision usually made to reach the kidney. This is done by making an incision through the peritoneum in front of the kidney, reaching inward to the gall bladder, discovering gallstones, and removing them through a button-hole incision made over the fundus of the gall bladder as it is held by the exploring hand against the anterior abdominal wall. He has also removed the appendix through the lumbar incision for kidney work. Through an enlarged gridiron incision for appendicitis he has often removed small fibroids, shortened ovarian ligaments, bisected ovaries, and he has performed anterior transplantation of the round ligaments, salpingostomy, and hysterosalpingostomy before or after removing the appendix. In cases presenting the clinical evidences of both appendicitis and gallstones, he makes a "compromise incision" through the right rectus muscle opposite the umbilicus, of sufficient length to admit the hand, which easily reaches the gall bladder and appendix respectively and, if need be, the other organs within the abdomen. In certain cases, says Ferguson, an examination of the abdominal organs would be highly satisfactory, although often the operator does not feel justified in opening through the abdominal wall for that purpose. The problem is solved in passing the hand and entire forearm into the abdominal cavity through the vagina. In order to furnish enough space for this purpose, it is imperative to cut through the mucous membrane of the vagina its whole length on each side postero-laterally. The mucous membrane being severed, the other structures stretch at once. The bare arm being smeared over with sterile vaselin, glides in with ease. A number of instances are cited in which this method of examination proved exceedingly useful.

27. **Pathogenesis of Exophthalmic Goiter.**—Gordon cites a case which he considers a valuable addition to the subject of the nervous origin of exophthalmic goiter and especially to its probable origin in the medulla; interesting also, from the standpoint of evolution of the symptoms, the involvement of cranial nerves, preceding a rapid, if not immediate, development of exophthalmic goiter. A middle-aged woman while attending to her usual duties noticed suddenly that she could not raise her eyes in the normal manner; she had to throw her head backward in order to be able to look up. On the following day she noticed an inability to turn the left eye externally. A few days later a gradually coming on of prominence of both eye globes was observed. A week later the neck became enlarged in front and at the same time palpitation of the heart with tremor of the hands made their appearance. In addition to the inability to raise both eyes (more on one side than on the other) and to turn both eyes externally (more on one side than on the other), there was also difficulty to turn the eyes upward and inward or downward and inward; finally the left pupil reacted very sluggishly to light. It was, therefore, an involvement of the third, fourth and sixth nerves, unequally distributed on both sides. The syndrome of Graves' disease was present in its entirety: exophthalmos, von Graefe's sign, goiter, tachycardia (pulse 120), and tremor.

28. **Chronic Headache Treated by Massage.**—Norstrom makes a running comment of the treatment instituted by him for chronic headache of inflammatory and muscular origin. The treatment consists of massage of the muscular insertions to the cranium, of the fleshy part of the trapezius, the sternocleidomastoid, and other muscles of the neck, performed for a time sufficient to remove inflammatory deposits.

29. **Vices of Blood Pressure.**—According to Bishop, the vices of blood pressure are threefold: First, primary low arterial tension, which is met in all enfeebling disease, in great physical emergencies, and following either disease of the heart structure, or failure of the vital force and tissues of the body. Second, high arterial tension, which indicates that the circulation is laboring under stress, and due to nervous causes, such as overwork, excitement, and dissipation, or chemical causes, such as the over-ingestion of food, or the failure of kidney elimination; indeed, all the causes which can arise from a life of mental hardship combined with physical luxury. Third, secondary low arterial tension, which represents the final outcome of pre-existing high arterial tension.

35. Fracture of the Spine.—As the result of a study of 244 cases, Burrell draws the following conclusions: Fractures of the spine may well be divided into two classes: First, fractures of the spine, with injury to the cord, and, second, fractures of the spine, without injury to the cord. It is not best to decide what the treatment of an individual case of fracture of the spine should be from the statistics, because the lesion varies so widely. In many cases of fracture of the spine it is impossible primarily to state whether or not the cord is crushed or pressed on by bone, blood or exudate, except by an open operation. Only by the persistence of total loss of reflexes, complete insensibility to touch and pain, and motor paralysis below the level of the lesion, can total transverse destruction of the cord be diagnosticated. If pressure on the cord is allowed to remain for many hours, irreparable damage may take place. Unless it is perfectly clear that the cord is irremediably damaged, an open operation to establish the condition of the cord and to relieve pressure is imperative as soon as surgical shock has been recovered from. In certain cases of fracture of the spine, when the cord is not injured, but is liable to injury from displacement of the fragments of a vertebra, rectification of the deformity and fixation of the spine may be used. If the cord is crushed, no matter what treatment is adopted, there will, of necessity, be a high rate of mortality.

37. Tubercular Conditions of Spine.—According to Willard, complete methodical and long-continued fixation of the spine in the position of hyperextension, with healthy surroundings in the sunlight, are the prime factors in securing new ossific deposit necessary to replace the carious bone. Laminectomy for paraplegia is advisable only after long-continued and patient treatment along these lines from one to two years, since the prognosis, especially in children, under these conditions, is favorable, and good powers of locomotion may be confidently expected. The operation is justifiable in selected cases in which loss of motion and sensation are progressively worse and the symptoms threaten life. If the tuberculous masses within the spine can be removed, and if extradural pachymeningitic deposits or pus can be taken away, improvement may be expected, and in many cases relief occurs. The operation has a mortality of about 25 per cent. from immediate shock, 36 per cent. within a month; while one-half the patients die within the year, their lives probably being shortened by the operative procedure. Cases of non-improvement and death equal nearly 65 per cent. Forcible immediate straightening of the kyphosis is an unsurgical and dangerous proceeding; it is liable to reawaken the tubercular disease and to weaken the column. Forcible gradual straightening by supporting the kyphotic area on a pedestal is a valuable agent in relieving deformity. The weight of the shoulders and pelvis can thus be utilized as straightening forces and the weight of the column thrown on the posterior arches. In this position it is permanently fixed by plaster of paris. Complete erasion of the carious bodies of the vertebræ is an uncertain operation; in the dorsal region requiring section of ribs, with danger of wounding the pleura. Wiring of the spinous processes has never been sufficiently tried to demonstrate its helpfulness. Spinal abscesses which contain only liquefaction or caseation products should be aspirated. When true pus has formed, drainage is advisable.

38. Surgical Treatment of Intraspinal Tumors.—Harte's paper is based on the records of 92 operations for spinal tumors, among which number 43 patients died, a total mortality of nearly 47 per cent. The nature of the tumor is recorded in 88 of the reported cases. It was sarcomatous in two-fifths of the whole number (37 cases); adhesions, thickenings, etc., hold second place, with 11 cases; then comes ecchinococcus, 8 cases; fibroma, 6 cases; syringomyelia, 5 cases; endothelioma, 4; psammoma, 3; cyst, 3; fibromyxoma, 2; osteoma, 2, and one each of myeloma, lipoma, lymphangioma, dermoid cyst, primary and secondary carcinoma and one tumor of bone, the nature of which is not stated. In only three instances in which the patient recovered from the operation did no improvement follow it. Two of these were cases of inoperable sarcoma, and the third was a case of syringomyelia. Of those patients, 49 in number, who survived the operation for some weeks or months, no less than 29, or 59 per cent., recovered their functions sufficiently to be classed as cured; 17, or 34 per cent., could be classed as improved by the operation; while in the condition of only three patients, or 6 per cent., as mentioned above, did the operation effect no change. Harte includes in his figures twelve cases in which symptoms of spinal tumor were produced by meningeal thickenings or adhesions. In at least five of these cases the patients had suffered from Pott's disease of the spine in previous years, and a kyphosis still remained; but no tuberculous process was found at the operation. There are 87 cases in which the situation of the tumor with regard to the dura is mentioned; in 50 of these it was extradural, and in 36 intradural—not such a very striking difference. The death rate, moreover, in the extradural cases was even higher than that of the intradural tumors, being 50 per cent. for the former and only 47.21 per cent. for the latter. It is interesting to note that among female patients the mortality of operation has been only 45 per cent., while among the male it is 57 per cent. In searching for an explanation of this marked difference, Harte noticed that sarcomata were found one-third oftener in males than in females, and supposes that this fact may have something to do with lessening the mortality among women. Most of the operations were on adults, nearly one-half being between 30 and 50 years of age. The extremes of life were 9 years, in a boy, and 65 years, in a woman. Those patients under 20 and over 50 gave the highest percentage of recoveries. The average duration of symptoms before the operation was two years and three months. In 12 patients symptoms had existed for less than six months, in 11 for one year, in 8 for one year and a half, in 12 for two years, in 11 for three years, in 7 for four years, and in 6 for periods varying from four to eighteen years. The duration of symptoms does not throw much light on the nature of the tumor. The average duration of symptoms in the patients with sarcoma was two and three-quarters years, in those with adhesions two and three-quarter years, in those with ecchinococcus two and one-half years, and in those with fibroma one and a half years; while in all other forms of growth the average was about two and one-eighth years. A history of injury is noted in only five cases—three sarcomata, a psammoma and an endothelioma. Of 82 cases in which the region of the spine affected is given, the upper dorsal region was involved in 33 cases, or over 40 per cent.; the tumor was found in the lower dorsal region in 24 cases, in the lumbosacral region in 14, and in the cervical region in 11 cases. As far as the results are concerned, it appears to be immaterial at what level the growth is found. The cause of death is given in 28 cases. One-half of these were due to shock and hemorrhage, or to infection and meningitis, there being 7 fatal cases under each of these categories. Eight patients died from exhaustion, three from recurrence of malignant growths, two from hypostatic pneumonia, and one from bedsores and sepsis. As regards the technic of the operation, it is essentially the same as when employed in traumatic cases. After the operation no rapid improvement in the patient's condition need be anticipated; indeed, the paralysis and the anesthesia are sometimes markedly aggravated by the interference with the spinal nerves. The pain, however, is nearly always remarkably relieved; and the patient is in a more hopeful frame of mind than before the operation. The after-treatment should be the same as in every serious operation.

39. Surgical Anatomy of Small Intestine and Its Mesentery. —The studies reported by Monks concern that part of the small intestine which extends from the end of the duodenum to the ileocecal valve, and which is known to anatomists as the jejuno-ileum. The nature of this paper is such that it does not admit of a satisfactory summary of all the points mentioned in it. There are certain features, however, which Monks emphasizes. He attempts to show: 1. That the relative shape of the mesentery and intestine *in situ* can be best understood by arranging the intestine in a series of alternating curves on a wire, thus putting all parts of the intestine and mesentery

gently on the stretch. 2. That the mesentery may be roughly divided into two portions: (1) a proximal or flat portion, which comprises about two-thirds or three-fourths of the mesentery, and (2) a distal or ruffled portion, the "ruffled border," which comprises the remaining one-third or one-fourth. 3. That the main sheets of the mesentery alternate from above downward, going first to the left, then to the right, and finally proceeding to the iliac regions and pelvis. 4. That the fold of mesentery which descends into the pelvis can usually be palpated from a wound in the lower abdomen, and that it forms a valuable guide for the finger in the attempt to reach the left abdominal fossa. Monks suggests that this fold be known as the pelvic fold of the mesentery. 5. That the part of the ileum which is about to enter the cecum can usually be picked up from a right iliac wound with the forefinger, which, after passing into the pelvis, is curved upward around "the pelvic fold of the mesentery." 6. That while the intestine, freed from its mesentery, is straight, or nearly so, the mesentery when attached to it obliges it to follow a curved and tortuous course. 7. That, when the gut is attached to the mesentery, the free border of the gut is several feet longer than its mesenteric border, and that the free border may, therefore, properly be called "the long side," and the mesenteric border "the short side" of the intestine. 8. That the influence of the mesentery is such that the intestine is thrown into a series of alternating loops of varying shapes, sizes and planes. 9. That kinks in the intestine are usually confined to the lateral aspect of the gut. 10. That a distended and paralyzed intestine, filled with gas or semiliquid contents, does not at once empty itself through an enterostomy wound, and that the cause of this is obstruction, not only from sharp curves and kinks, but also from outside pressure on the tube, and, still further, because the fluid portions are in the dependent loops, where they act as traps to obstruct the passage of gases along the tube. 11. That, unless the intestine be "gathered up" on the tube, it is impossible to pass any instrument, hard or soft, straight or curved, into the gut without probability of soon engaging the wall of the intestine, usually in its free border. And, finally (12), that, when the size of the wound and its situation will permit, the surest method, at least on the cadaver, of determining which is the proximal and which the distal end of a loop of intestine is by palpation of the mesenteric root between the thumb and fingers of one hand.

40. **Infection of Knee Joint.**—Flint analyzes 310 cases and *summarizes his paper as follows: Non-penetrating injuries,* penetrating injuries, traumatic or operative, and knees independent of any injury occurring in the course of some other infectious process, or not, may present signs and symptoms not to be distinguished in the absence of bacteriologic examination from the cardinal sign and symptoms of infection. Certain of these cases are undoubtedly infected, but the data at command do not allow these to be distinguished from such as may be due to trauma and those possibly due to toxins secondary to infection elsewhere. The knee joint has certain germicidal powers. One out of every 22 operations on clean knees becomes sufficiently infected to demand operation (4.6 per cent.). One out of every 9 operations for recent (5 days) traumatic non-penetrating injury becomes sufficiently infected to demand operation (11 per cent.). One out of every 35 operations for pathologic conditions other than traumatic injuries more than five days old becomes sufficiently infected to *demand operation and drainage of the joint* (2.9 per cent.). One out of every 22 operations for simple fracture of the patella becomes sufficiently infected to demand operation (4.6 per cent.). One out of every 71 operations for fracture of the patella done after the fifth day becomes sufficiently infected to make operation a necessity (1.2 per cent.). One out of every 9 or 10 operations for fracture of the patella done before the fifth day becomes sufficiently infected to demand operation (10.5 per cent.). Three out of every five cases of penetrating injury to the knee joint become sufficiently infected to require operation (60 per cent.). Of compound fractures of the patella, seven out of nine become sufficiently infected to demand operation (78 per cent.). Certain knees subjected to non-penetrating injury and not operated on become sufficiently infected to require operation (10 per cent. of the operative septic cases). Certain knees become sufficiently infected to require operation *where no history* of trauma or other evident septic focus in the body exists (13 per cent. of the operative septic cases). Certain knees become sufficiently infected to require opening and draining the joint in the course of some evident focus of infection elsewhere in the body (11 per cent. of the operative septic cases). One out of every nine patients with infected knees which have been opened and drained dies (11 per cent.; some after previous amputation). One out of every fifteen patients with infected knees which have been opened and drained comes to amputation before recovery (6.6 per cent.). One out of every thirty-one infected knees which have been *opened and drained is resected (3.3 per cent.).* Most knee joints which have been infected, opened, drained, and recovered show varying degrees of functional disability, from slight limitation of motion to complete ankylosis, with or without subluxation. The average stay in the hospital of a patient operated on for infected knee joint is between two and three months. When it is once determined to open and drain the joint, the operation should be as radical as possible at the start. The position of the leg should be that giving the best mechanical drainage, i. e., the patient should be face down. The risk of infection is greatest in penetrating wounds of the knee (60 per cent.). The *risk of infection is least in operations* on clean knees and where there has been no recent trauma (3 to 4 per cent.).

3. **New Operation for Moderate Myopia.**—Maddox' operation consists in flattening the cornea, first in one meridian and then at right angles. The operation was tried successfully on a young man who was barred from entering the army medical service because of a very slight myopia in one eye. Without anesthesia Maddox first dissected up a conjunctival flap and threw it over the cornea, then introduced a triangular iridectomy knife between the reflected conjunctiva and the sclera, and entered the anterior chamber. The iris prolapsed again and again, especially after enlarging the incision above and below with the probe-pointed knife, which forms the next stage of the operation, for only a very large incision is capable of producing a regular flattening of the cornea. At last the iris was comfortably reposed and the conjunctival sutures inserted so as to exert considerable traction on the flap. Healing was painless and uninterrupted. The second incision was made about three months afterward, the incision being made with an ordinary cataract knife, this time downward, with the same good result as before. The patient succeeded in passing his physical examination, showing that the operation was a success.

5. **Diagnosis of Varieties of Pleural Effusion.**—Hadley calls attention to the means at our disposal for diagnosing the nature of any particular pleural effusion. These are clinical, cultural, by inoculation, by tuberculin, Jousset's microscopic method, cytodiagnosis and serum diagnosis. In conclusion he submits the following suggestions: 1. It is most important to appreciate the frequently tuberculous nature of pleural effusions. 2. Clinically, if an effusion takes place without any apparent cause, either in the shape of trauma, of inflammation from without, or of some definite trouble in the lung, mediastinum, or pericardium, or if there is not heart or kidney disease to account for it, and if there is no strong rheumatic taint, then it is almost surely tuberculous. 3. Pathologically we have several very reliable ways of definitely determining its true nature, the two most reliable as well as convenient, being (a) the estimation of the cell content of the fluid, (b) Jousset's method of demonstrating the presence of tubercle bacilli.

6. **Posture and Adventitious Breath Sounds.**—The point brought out by Ransom is that not only in cases of bronchitis and emphysema, but in a few cases of limited pulmonary tuberculosis, adventitious sounds may be heard in the supine while absent in the erect position.

8. **Human and Bovine Tuberculosis.**—As the result of an observation of 3,500 cases of tuberculosis, with, in addition, a study of 650 autopsies on such cases, Raw expresses the opinion that human and bovine tuberculosis are separate and distinct varieties of disease, but that the human body is susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases are so rarely seen together in the human that there seems to be some ground for presuming that they are antagonistic to each other, and that bovine tuberculosis may possibly confer an immunity against human tuberculosis. Raw believes that primary intestinal tuberculosis, tabes mesenterica, and other tuberculous affections of the serous membrane in children are probably bovine tuberculosis conveyed by milk and are not true human tuberculosis, although the bacillus of Koch is found in them all. He believes also that the bovine bacillus is more virulent for children than the bacillus of human tuberculosis.

13. **Secondary Parotitis.**—On studying the evidence presented by 6 cases Bucknall concludes that it is highly probable that secondary parotitis is invariably due to an infection of Stenson's duct, dependent on a septic condition of the mouth, and that its onset may be prevented by attention to the following details: 1. The patient's mouth should be carefully cleansed and rendered aseptic before operations and at the commencement of long febrile illnesses. If necessary, causes of nasal obstruction leading to mouth breathing, such as adenoids, should be removed. 2. The anesthetic apparatus should be sterile. 3. The mouth should be periodically cleansed afterward, especially after every attack of vomiting. 4. The bowels should be opened early, and food by the mouth, and especially solid food, should be given as soon as possible. 5. Opium should not be given unless absolutely necessary. 6. The head should not be placed too low nor the binder fixed

gently on the stretch. 2. That the mesentery may be roughly divided into two portions: (1) a proximal or flat portion, which comprises about two-thirds or three-fourths of the mesentery, and (2) a distal or ruffled portion, the "ruffled border," which comprises the remaining one-third or one-fourth. 3. That the main sheets of the mesentery alternate from above downward, going first to the left, then to the right, and finally proceeding to the iliac regions and pelvis. 4. That the fold of mesentery which descends into the pelvis can usually be palpated from a wound in the lower abdomen, and that it forms a valuable guide for the finger in the attempt to reach the left abdominal fossa. Monks suggests that this fold be known as the pelvic fold of the mesentery. 5. That the part of the ileum which is about to enter the cecum can usually be picked up from a right iliac wound with the forefinger, which, after passing into the pelvis, is curved upward around "the pelvic fold of the mesentery." 6. That while the intestine, freed from its mesentery, is straight, or nearly so, the mesentery when attached to it obliges it to follow a curved and tortuous course. 7. That, when the gut is attached to the mesentery, the free border of the gut is several feet longer than its mesenteric border, and that the free border may, therefore, properly be called "the long side," and the mesenteric border "the short side" of the intestine. 8. That the influence of the mesentery is such that the intestine is thrown into a series of alternating loops of varying shapes, sizes and planes. 9. That kinks in the intestine are usually confined to the lateral aspect of the gut. 10. That a distended and paralyzed intestine, filled with gas or semiliquid contents, does not at once empty itself through an enterostomy wound, and that the cause of this is obstruction, not only from sharp curves and kinks, but also from outside pressure on the tube, and, still further, because the fluid portions are in the dependent loops, where they act as traps to obstruct the passage of gases along the tube. 11. That, unless the intestine be "gathered up" on the tube, it is impossible to pass any instrument, hard or soft, straight or curved, into the gut without probability of soon engaging the wall of the intestine, usually in its free border. And, finally (12), that, when the size of the wound and its situation will permit, the surest method, at least on the cadaver, of determining which is the proximal and which the distal end of a loop of intestine is by palpation of the mesenteric root between the thumb and fingers of one hand.

40. **Infection of Knee Joint.**—Flint analyzes 310 cases and summarizes his paper as follows: Non-penetrating injuries, penetrating injuries, traumatic or operative, and knees independent of any injury occurring in the course of some other infectious process, or not, may present signs and symptoms not to be distinguished in the absence of bacteriologic examination from the cardinal sign and symptoms of infection. Certain of these cases are undoubtedly infected, but the data at command do not allow these to be distinguished from such as may be due to trauma and those possibly due to toxins secondary to infection elsewhere. The knee joint has certain germicidal powers. One out of every 22 operations on clean knees becomes sufficiently infected to demand operation (4.6 per cent.). One out of every 9 operations for recent (5 days) traumatic non-penetrating injury becomes sufficiently infected to demand operation (11 per cent.). One out of every 35 operations for pathologic conditions other than traumatic injuries more than five days old becomes sufficiently infected to demand operation and drainage of the joint (2.9 per cent.). One out of every 22 operations for simple fracture of the patella becomes sufficiently infected to demand operation (4.6 per cent.). One out of every 71 operations for fracture of the patella done after the fifth day becomes sufficiently infected to make operation a necessity (1.2 per cent.). One out of every 9 or 10 operations for fracture of the patella done before the fifth day becomes sufficiently infected to demand operation (10.5 per cent.). Three out of every five cases of penetrating injury to the knee joint become sufficiently infected to require operation (60 per cent.). Of compound fractures of the patella, seven out of nine become sufficiently infected to demand operation (78 per cent.). Certain knees subjected to non-penetrating injury and not operated on become sufficiently infected to require operation (10 per cent. of the operative septic cases). Certain knees become sufficiently infected to require operation where no history of trauma or other evident septic focus in the body exists (13 per cent. of the operative septic cases). Certain knees become sufficiently infected to require opening and draining the joint in the course of some evident focus of infection elsewhere in the body (11 per cent. of the operative septic cases). One out of every nine patients with infected knees which have been opened and drained dies (11 per cent.; some after previous amputation). One out of every fifteen patients with infected knees which have been opened and drained comes to amputation before recovery (6.6 per cent.). One out of every thirty-one infected knees which have been opened and drained is resected (3.3 per cent.). Most knee joints which have been infected, opened, drained, and recovered show varying degrees of functional disability, from slight limitation of motion to complete ankylosis, with or without subluxation. The average stay in the hospital of a patient operated on for infected knee joint is between two and three months. When it is once determined to open and drain the joint, the operation should be as radical as possible at the start. The position of the leg should be that giving the best mechanical drainage, i. e., the patient should be face down. The risk of infection is greatest in penetrating wounds of the knee (60 per cent.). The risk of infection is least in operations on clean knees and where there has been no recent trauma (3 to 4 per cent.).

3. **New Operation for Moderate Myopia.**—Maddox' operation consists in flattening the cornea, first in one meridian and then at right angles. The operation was tried successfully on a young man who was barred from entering the army medical service because of a very slight myopia in one eye. Without anesthesia Maddox first dissected up a conjunctival flap and threw it over the cornea, then introduced a triangular iridectomy knife between the *reflected* conjunctiva and the sclera, and entered the anterior chamber. The iris prolapsed again and again, especially after enlarging the incision above and below with the probe-pointed knife, which forms the next stage of the operation, for only a very large incision is capable of producing a regular flattening of the cornea. At last the iris was comfortably reposed and the conjunctival sutures inserted so as to exert considerable *traction* on the flap. Healing was painless and uninterrupted. The second incision was made about three months afterward, the incision being made with an ordinary cataract knife, this time downward, with the same good result as before. The patient succeeded in passing his physical examination, showing that the operation was a success.

5. **Diagnosis of Varieties of Pleural Effusion.**—Hadley calls attention to the means at our disposal for diagnosing the nature of any particular pleural effusion. These are clinical, cultural, by inoculation, by tuberculin, Jousset's microscopic method, cytodiagnosis and serum diagnosis. In conclusion he submits the following suggestions: 1. It is most important to appreciate the frequently tuberculous nature of pleural effusions. 2. Clinically, if an effusion takes place without any apparent cause, either in the shape of trauma, of inflammation from without, or of some definite trouble in the lung, mediastinum, or pericardium, or if there is not heart or kidney disease to account for it, and if there is no strong rheumatic taint, then it is almost surely tuberculous. 3. Pathologically we have several very reliable ways of definitely determining its true nature, the two most reliable as well as convenient, being (a) the estimation of the cell content of the fluid, (b) Jousset's method of demonstrating the presence of tubercle bacilli.

6. **Posture and Adventitious Breath Sounds.**—The point brought out by Ransom is that not only in cases of bronchitis and emphysema, but in a few cases of limited pulmonary tuberculosis, adventitious sounds may be heard in the supine while absent in the erect position.

8. **Human and Bovine Tuberculosis.**—As the result of an observation of 3,500 cases of tuberculosis, with, in addition, a study of 650 autopsies on such cases, Raw expresses the opinion that human and bovine tuberculosis are separate and distinct varieties of disease, but that the human body is susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases are so rarely seen together in the human that there seems to be some ground for presuming that they are antagonistic to each other, and that bovine tuberculosis may possibly confer an immunity against human tuberculosis. Raw believes that primary intestinal tuberculosis, tabes mesenterica, and other tuberculous affections of the serous membrane in children are probably bovine tuberculosis conveyed by milk and are not true human tuberculosis, although the bacillus of Koch is found in them all. He believes also that the bovine bacillus is more virulent for children than the bacillus of human tuberculosis.

13. **Secondary Parotitis.**—On studying the evidence presented by 6 cases Bucknall concludes that it is highly probable that secondary parotitis is invariably due to an infection of Stenson's duct, dependent on a septic condition of the mouth, and that its onset may be prevented by attention to the following details: 1. The patient's mouth should be carefully cleansed and rendered aseptic before operations and at the commencement of long febrile illnesses. If necessary, causes of nasal obstruction leading to mouth breathing, such as adenoids, should be removed. 2. The anesthetic apparatus should be sterile. 3. The mouth should be periodically cleansed afterward, especially after every attack of vomiting. 4. The bowels should be opened early, and food by the mouth, and especially solid food, should be given as soon as possible. 5. Opium should not be given unless absolutely necessary. 6. The head should not be placed too low nor the binder fixed

too tightly and the dorsal decubitus should be given up as soon as possible. There is also evidence to show that the process of duct infection responsible for ascending parotitis is due to one or other of the following causes: 1. The presence of specific micro-organisms in the buccal cavity, such as the special organisms of mumps, typhoid fever, and probably typhus fever and pneumonia also. 2. An increase in the number or virulence of the normal buccal organisms and especially of the staphylococci. 3. Anything interfering with the quantity or quality of the saliva protectively draining down the duct. Either an actual obstruction, such as a calculus, or an alteration in the saliva secreted, resulting from general ill-health or the administration of drugs may produce this effect.

14. **Physiologic Albuminuria.**—Wright and Ross claim that when it is found that a patient possesses a normal excretory quotient, and that his albuminuria can be abolished by diminishing the hydrostatic pressure on the renal capillaries and by increasing the coagulability of the blood, there is every reason to conclude that the kidney is free from organic disease and that life is no more endangered than it would be if the patient were the subject of urticaria.

15. **Operation for Volkmann's Contracture.**—Rolland describes an operation which he performed on a girl 6 years old for Volkmann's contracture following a fracture of the radius and ulna. The whole left upper limb having been very thoroughly cleaned and compressed on the previous day, an operation was performed a little more than four months after the accident. Anesthesia was produced by ethyl chlorid followed by ether. A tourniquet was applied round the lower third of the arm and an incision was made along the middle third of the radial border of the forearm; the wound was placed slightly in front of the interval between the radial extensors of the wrist and the special extensors of the thumb. The posterior border of the radius can be easily felt in this interval before an incision is made, but a wound over the extensor carpi radialis longior gives a better access to the radius. This tendon and the radial nerve protected by it were drawn forward and the extensor carpi radialis brevoir was retracted in the opposite direction. The radius, having been well cleared of soft parts, was drilled at two points, one and a quarter inches apart, and then a portion of it three-quarters of an inch long was removed by the aid of a small saw. The piece of bone removed extended from the pronator teres insertion to the pronator quadratus; some of the fibers of the former had to be detached from the bone to allow the removal of enough bone. The wound was now covered by a temporary dressing, during the removal of a similar portion of the ulna through a longitudinal incision along its subcutaneous border. Care was taken to divide the ulna an inch higher than the radius so as to prevent cross union by callus. The bone ends were brought together and fixed in apposition by means of fine silver wires, one for each bone. The bones were soft and the wire cut its way out by fissuring the upper ulnar fragment and another hole had to be drilled farther away from the section; this was difficult and it demonstrated the wisdom of drilling the bones before sawing them. The drill holes in the radius had been so directed that when the wire was tightened the lower fragment of the radius rotated into a position of semi-supination. Thus the troublesome fixation of the hand in full pronation was corrected. During the operation it was noticed that the deeper flexors in front of the radius and ulna were firm and fibroid. On removing the tourniquet there was but little bleeding, so the wounds were at once sutured and the limb was enveloped with aseptic dressings and lightly secured in good position on an internal angular splint in order to preserve the semi-prone attitude of the hand. When the operation had been completed, the wrist and fingers could be extended almost, but not quite, into a straight line with the forearm. The splint was long enough to maintain this correction. The operation lasted for forty minutes. After the fourth day passive movements of the fingers were carried out several times daily and the child was encouraged to move the fingers from the first day. When the bones had united, pronation and supination were also practiced diligently and massage also was carefully performed after the ninth day. The child can now use the hand for most things, has a good range of movement in the fingers, a powerful grip, and supination and pronation are very well performed.

17. **Impacted Gallstone in Colon.**—The symptoms in the case reported by Smith did not, at any time, point to gallstone disease. There was some pain across the abdomen in the region of the umbilicus, occasional attacks of hiccough and frequent vomiting. An operation having been decided on, the abdomen was opened in the middle line below the umbilicus. Examination revealed the presence of a mass of adhesions in the region of the gall bladder. A second incision was made through the upper part of the right rectus, and it was found that many bands of adhesions were binding down the transverse colon to the neighborhood of the gall bladder. That part of the colon beyond this point was empty and collapsed. Separation of the adhesions was successful in relieving obstruction. Gauze drains were inserted and the wounds were closed. The patient's condition becoming worse, the colon was again exposed and opened under local anesthesia and a Paul's tube tied in. The patient died shortly afterward. At the autopsy the large intestine was found to be distended as far down as the brim of the pelvis, at which point a gallstone of the size and shape of a hen's egg was found impacted. The transverse colon and the gall bladder were found imbedded in a mass of adhesions and a communication was found between their cavities. The common bile duct was obliterated. Other calculi were found in the gall badder.

24. **Malaria in Algiers During 1904.**—The French have been masters of Algeria for seventy-four years, but the ravages of malaria recur, in certain seasons, almost as severely as during the first years of their occupancy. About 98,774 cases of malaria were known in 1904, with 7,432 deaths from this cause. The total mortality during the corresponding three months in 1903 was 2,280, while it rose to 9,927 in 1904, mainly due to the recrudescence of malaria. In the French army of 44,065 men, stationed in Algeria, 10,065 cases of malaria were reported, with 47 deaths from this cause. The season was an unusually wet one. The physicians, teachers and public officials in Algeria now have undertaken a campaign of education to teach the people how to avoid malarial infection. It is proposed to introduce the "malaria catechism" used in Corsica. The children there are obliged to learn the answers to a set of questions in regard to malaria, its causes, mode of dissemination and its prophylaxis. Drs. Soulié and Moreau have been instrumental in founding an antimalaria league in Algeria, which is now introducing prophylactic measures on a large scale.

28 *La langue auxiliare, L'Esperanto (artificial, auxiliary language). G. Vitoux.

27. **Effectual Serum Treatment of Hemophilia.**—Weil presents some views in regard to hemophilia which explain its nature. and suggest effectual treatment. His experience has demonstrated to his satisfaction that the lack of coagulation in the blood of hemophilics is not due to the presence of an anticoagulating body. It is the result of the absence or modification of certain substances normally in the blood, such as the coagulating ferment, the fibrin ferment or the thrombase. If traces of these ferments from normal serum are added to a specimen of hemophilic blood, coagulation proceeds as under normal conditions. Hemophilic serum added to normal blood does not affect its coagulation. On the other hand, normal serum added to hemophilic blood causes normal coagulation in the latter. Animal serums have the same action in this respect as human serum, but less intense. In a typical case of

hemophilia with excessive, protracted hemorrhages after slight traumatisms, never spontaneous, intravenous injection of beef serum had a remarkable effect in inducing coagulation in the blood drawn from the finger or elbow. Before the injections blood from a vein in the elbow showed no signs of coagulation until after 25 to 75 minutes, but after intravenous injection of 15 c.c. of beef serum blood from the finger coagulated in 3 minutes, and that from the elbow in from 5 to 10. A week later 10 c.c. of human blood were injected, and by the fifth day coagulation was almost immediate. The interval before coagulation gradually lengthened until in two weeks it was from 20 to 55 minutes. Another intravenous injection of 15 c.c. of beef serum reduced the interval again to less than 8 minutes. This serum treatment or vaccination of the hemophilic blood is only passive. The curative action of the injected serum becomes evident in 48 hours and continues marked for about a week, when it gradually subsides. This passive vaccination is similar to that observed by Widal in his preventive serum treatment of paroxysmal hemoglobinuria. Too large doses produce the opposite effect. Weil concludes by recommending this method of serum treatment, or rather opotherapy, as a preventive measure in case an operation is contemplated on a hemophilic. In the case described the patient had a tooth pulled after an intravenous injection of the foreign serum, and, for the first time in his life, the traumatism of the operation was not followed by excessive and prolonged hemorrhage. His gums did not bleed any more than is usually observed in normal individuals.

28. **International Language: Esperanto.**—THE JOURNAL recently referred to an international congress where all spoke the same language, although 1,500 members had gathered from all parts of the civilized world. This artificial, auxiliary language was invented by a Polish physician, Dr. Zamenhof of Warsaw, in 1887, and Vitoux claims that it is a masterpiece of simplicity and clearness. The dictionary contains only the root words, the thirty affixes that modify them being applied with mathematical exactness to define the sense. The plan of the language is readily understood and three or four months of practice are sufficient to master it. Hachette of Paris publishes, in Esperanto, the *Internacia Scienca Rivuo*, and it is announced that a medical journal, published exclusively in Esperanto, will soon be founded.

40. **Pyonephritis, Pyelitis and Compression of Ureter.**—A woman of 33, in the sixth month of her first pregnancy, was attacked suddenly with violent pains in the left side of the back, and fever. The urine showed no marked changes, but other signs indicated a tumor in the kidney region, and the operation revealed pyonephrosis. The cause was assumed to have been compression of the left ureter by the gravid uterus, and the patient was ordered to lie exclusively on the right side. Recovery was prompt and the pregnancy continued undisturbed to term. Sippel ascribes greater importance to compression of the ureter than is generally accepted nowadays. Abrupt compression might induce troubles leading even to eclampsia, without permanent enlargement of the ureter sufficient to attract attention at the autopsy. Systematic reclining on the sound side, supplemented with the usual measures, will frequently avert or banish disturbance from this compression pyelitis. If all fails, then the uterus should be emptied. Compression of the ureter should be suspected when fever and sudden pain develop during a pregnancy. In some cases, appendicitis has been diagnosed, but the appendix region was found sound at the operation and the disturbances persisted until expulsion of the fetus, when they subsided. The compression may interfere with the circulation into and out of the kidney, and relief may be obtained by decapsulation, as Edebohls has reported in a case of eclampsia.

44. **Improved Technic for Over-pressure Anesthesia.**—The head of the patient is enclosed in an air-tight glass box, to which compressed air is supplied. The arms of the anesthetist are inserted into the box through openings, with an air-tight rubber cuff fitting around the wrist. There are also additional openings for the arms of an assistant. The illustration gives a view of the combination of the compressed-air apparatus, with the chloroform-oxygen apparatus which supplies mixed chloroform and oxygen for the anesthesia. Both apparatus have been simplified and improved. The introduction of a bellows tank provides a reservoir for the compressed air. A manometer shows the varying pressure, while the register of a second manometer shows the constant pressure in the box in which the patient breathes. There is also a glass bell, in which hangs a rubber bag, in direct communication with the breathing box; this bag is subjected inside and outside to the same pressure as the patient's lungs.

45. **Minor Aids to Examination of Patients Presenting Brain Troubles.**—Among the minor points to which Liepmann calls attention is the danger of incorrectly diagnosing apraxia in cases of paralysis from a focus in the cortex. This is especially liable to occur when there is simultaneous aphasia. In examining such a patient, one is liable to accept mental impairment from the lack of the proper response. This error can be avoided by systematically seeking for some group of muscles which is not affected. The patient may be able to respond correctly with the muscles of the leg or face when the failure to respond correctly with the hand might be interpreted as due to inability to understand the orders given. Another means is by asking a nonsensical question, such as "Has an eagle wings? Has a horse wings?" the expression of the patient's face answering the question as plainly as words. To determine hemianopia, he strews some beans on the table, without the patient noticing it, and then asks him to pick them up. If he picks them all up, not much is learned, but if he overlooks all on his left side a defect on that side is more than probable. Another point is that persons unable to read words are yet sometimes capable of reading figures. Another good test for mind blindness is to have the patient pick up grains of different sizes strewn on a table. The smallest size perceived is an indication of the visual capacity. Congenital may be differentiated from acquired color blindness by the lack of hesitation in sorting out articles of different colors. In testing cases of perseveration, only the first response in each series of tests can be regarded as demonstrative. He gives a number of means to test apraxia, and lays special stress on the natural actions of the patient, how he combs and brushes his hair, takes up a glass of water to drink when he is thirsty or greets a friend—the information thus derived is more important than that obtained when the patient performs the same actions on command.

47. **Membranous Enteritis.**—Elsner's article issues from Boas' clinic. He believes that colitis mucosa and colica mucosa are neuroses affecting the secretion of mucus. They are generally accompanied by other nervous symptoms, and the patients usually notice that the pains and evacuation of mucus follow psychic excitement. The secretion of mucus may be subject to nervous influences in other organs, as we witness in membranous dysmenorrhea and in croupous bronchitis. This nervous hypersecretion generally develops on the basis of some catarrhal intestinal affection. He describes the postmortem findings in 2 cases and reviews what has been published on the

been done, the patient suddenly stopped breathing and the pulse became imperceptible, but both were restored by two minutes of artificial respiration. On account of the necessary manipulations for this, the asepsis of the field was dubious, and consequently the soft parts were held back with a roll of gauze on each side and the skin was sutured over them. Three days later the operation was continued and the removal of the tumor then proved an easy task. Among the conclusions drawn from this experience is the refutation of the assumption that intradural tumors are necessarily small. Also that the injury from the tumor is liable to be felt more seriously in the part of the spinal cord opposite to the tumor than in the part directly contiguous to it. The patient in the present case recovered so completely that her right arm is now stronger than the left, notwithstanding its long paralysis. The operation was undertaken about eleven months after the first symptoms of trouble had been noted. Operating in two sittings was possibly one of the main factors in the success obtained.

63. **Cryoscopy of Blood and Serous Fluids.**—This article by Cohn contains the bibliography of the subject, in addition to extensive personal research. He found the freezing point of normal blood between —0.517 and —0.562 C. He noted that it was frequently abnormally low in chronic nephritis and generally so in uremia and leukemia. In febrile affections it was abnormally high. Contrary to what is observed in animals, inflammatory fluids in the pleura, peritoneum, spinal cord or brain are not isotonic with the blood serum in man. He was unable to find any particular molecular concentration of the blood characteristic for any special kind of nephritis.

64. **Prospects for Early Diagnosis of Intestinal Cancer.**—Boas analyzes his experience and comes to the conclusion that the prospects for early diagnosis of cancer in the intestines and its successful removal are not very promising. The really incipient stage of intestinal cancer is beyond our powers to detect. Early application to a physician and early diagnosis do not guarantee the possibility of its radical removal in all cases, and not even in the majority of gastrointestinal cancers. He cites a number of instances to show further that good results are possible even when the symptoms have long existed. The kind and the malignancy of the tumor are the deciding factors, not the promptness with which the affection is diagnosed after the first symptoms appear. Our very earliest diagnosis, as a rule, is too late. Metastases or ascites are found even in the apparently very earliest stages in a large proportion of cases. He does not believe that gastroscopy will ever acquire much importance, as the very first subjective symptoms are generally found accompanied by advanced objective changes in the majority of cases of intestinal or stomach cancer, even in case of cancers of the rectum which are more accessible than others. Much might be accomplished by better training of physicians in the diagnosis of cancer, and Boas here reiterates his plea for the establishment of cancer-examining stations for suspicious cases. This would reduce the number of investigated but incorrectly diagnosed cases of rectal cancer, and also of cancer of the colon. The latter have a better prognosis than cancer elsewhere in the gastrointestinal tract. The malignancy of cancer, he thinks, lies not only in the neoplasm itself, but in the insidious latency of its development.

67. **Idiopathic Osteopsathyrosis.**—Looser reports the results of examination of the amputated leg of a patient with typical congenital imperfect and tardy bone formation. It has convinced him that the condition is a clinically and anatomically well-defined affection, as he relates in detail.

68. **Guaiacol in Treatment of Tuberculosis of the Kidneys.**—Schüller describes two cases of tuberculosis of the kidneys in which he realized a complete cure by internal and local application of guaiacol for months. His first patient was a man of 40, with evidences of apical tuberculosis, bacilli in sputa, bilateral tuberculous processes in the testicles and tubercle bacilli and kidney epithelial cells and red corpuscles in the urine. The process in the testicles healed completely after seven injections of a guaiacol-iodoform-glycerin preparation, combined with internal administration of guaiacol for several months. The drug was then suspended for a few months, and then resumed for a few weeks, by which time no further evidences of tuberculosis in any organ could be detected. The patient has been definitely cured, now for more than thirteen years. Schüller's second patient was a little girl with a tuberculous process in the hip joint and evidences of a tuberculous affection of the kidneys. Guaiacol topically and internally was followed by the cure of the hip process and the subsidence of all symptoms on the part of the urinary apparatus, without recurrence during the nine years since. He consequently suggests the advisability of guaiacol treatment in the incipient stages of tuberculosis of the kidneys and bladder, also after removal of one kidney to protect its mate, and, further, in the cases in which a partial operation has been done on the kidney, in order to hasten and to promote the permanent recovery of the organ. Some of his patients have taken guaiacol for more than four years without inconveniences. He gave it in 200 cases of tuberculosis between 1891 and 1899, and 37 of the patients were materially improved or quite cured by it. The kidneys are especially adapted for this mode of treatment, as part of the guaiacol is eliminated through these organs. His practice is to give it in small fractional doses continually. His dose for adults is from 12 to 15 or even 20 drops of pure guaiacol in from 130 to 150 or 200 gm. of water, shaken until dissolved, and fractioned into five or six portions. Children take from 3 to 23 drops, according to age. No preparation of guaiacol has proved so effectual in his experience as the pure article.

69. **Periarteritis Nodosa.**—Versé has been able to find only 20 cases of this affection in the literature. Men between 20 and 35 were principally affected, but the disease has been observed in an infant under 3 months and in one man of 52. The course is always more or less acute, terminating fatally in three or four months. He describes the history and findings in a typical case personally observed. Signs of old nephritis were found and a peculiar affection of the smaller arteries in the liver, mesentery, intestine, stomach and spermatic cord, characterized by the formation of small spindle-shaped or round aneurisms, with thrombosis of the vessels affected. In 5 of the published cases syphilitic antecedents were certain, and Schmorl has reported one in which the multiple lesions entirely retrogressed under antisyphilitic treatment. At the autopsy years later, the vessels were found normal, but in the liver, kidneys and heart traces of the old affection could be detected in the form of minute fibrous foci closely related to the vessels. Periarteritis nodosa may thus be regarded as a special form of syphilis of the blood vessels.

70. **Nasal Diphtheria with Scarlet Fever.**—Uffenheimer describes a fatal case of what appeared to be diphtheria affecting the nose during the last stages of scarlet fever. He argues that it was not true diphtheria and that the membrane formation was exclusively the work of the scarlet fever infection. He calls the condition nose diphtheroid, with scarlet fever. A very few non-virulent diphtheria bacilli were found in the midst of countless numbers of streptococci.

71. **Treatment of Suppuration in Maxillary Sinus.**—Strubell takes two maxims as his guide: To rinse only so long as the patient tolerates it without objecting, and to reject all radical measures which leave a permanent communication between the mouth and the sinus. He describes his methods and technic in detail.

subject, affirming, in conclusion, that there are no grounds for the assumption that membranous enteritis is a special affection *sui generis.*

48. **Zigzag Incision in Appendicitis.**—Riedel's motto now is: "Operate on a patient with appendicitis as soon as you see him." He protests against the term "early operation" and claims that it should be called the "proper operation." The tumor should not be directly cut into, and for this reason he prefers what he calls the zigzag incision. He has had a mortality of 7 per cent. in 357 cases, and states that 19 out of the 21 deaths might have been prevented if the patient had applied to a physician earlier.

49. **Gangrene of Testicle After Gonorrhea.**—Buschke knows of only 17 cases of gangrene of the testicle after gonorrhea. In the case personally observed, the gonorrhea was mild, but the inflammation in the testicle progressed to gangrene. The patient was a robust man of 27. A bacillus resembling the colon bacillus was cultivated from the secretions, and Buschke believes that the gangrene was a secondary process. Gonococci have not been found in the gangrene to date. Trauma seems to afford a predisposition.

50. **Dressings of Fuller's Earth.**—Aufrecht is enthusiastic in regard to the advantages of fuller's earth as a dressing for wounds. It is slightly astringent, sucks up the secretions and prevents putrefaction, all qualities of the ideal dressing. The best way in which to use it is with gauze impregnated with it; the gauze is first treated with an ammoniacal soap, with or without a small proportion of salicylic acid or aluminum acetate. The absorbing power of gauze thus impregnated with fuller's earth is three times that of ordinary gauze, while its antiseptic properties, he claims, are superior to those of iodoform.

55. **Regeneration of Nerves.**—Perthes describes the particulars of a case of recurring trigeminal neuralgia in which five different operations for its relief had been done. The patient finally succumbed to the progress of a valvular defect, and the autopsy revealed regeneration of the nerves where the Gasserian ganglion had been extirpated, and also after the various resections and other operations on the nerves involved. In a second case the neuralgia recurred after a Thiersch operation on the nerve, but was abolished again by removal of the regenerated nerve. Experiments on dogs are reported which show that regeneration of a nerve was almost certain to occur after a few months, when it was merely resected, while the mere severing of the nerve, with the interposition of a gold filling between the ends of the stumps in the infraorbital canal, prevented regeneration. The experimental results observed promise good results in man from the use of a dentist's filling to plug the canal in the bone after severing or extracting the inferior infraorbital or alveolar nerve.

57. **Fractures of Pelvis.**—Stolper's collection of fractured pelves now numbers 33, while the clinical cases observed bring the total to 64. He is convinced that many fractures of the pelvis are not recognized, and describes the points useful in diagnosis. It is difficult and sometimes impossible to diagnose a concomitant rupture of the bladder; consequently all dubious cases should be sent at once to a surgical hospital. Exploratory laparotomy is more than justified, and fine results were attained in the 50 cases on record in which a ruptured bladder received operative treatment. Stolper's article fills nearly 100 pages, and presents the subject from every point of view, with special reference to injuries of the urethra and bladder.

62. **Successful Removal of Spinal Tumor.**—The patient was a robust young woman, previously healthy, who suddenly experienced violent pains in the back of the neck and in the right arm. Symptoms of right radial paralysis developed with other indications of compression of the cervical spinal cord. Tentative antisyphilitic treatment produced no effect and the affection continued a gradually progressive course. In pachymeningitis, the radial domain is generally spared, while the trouble is usually bilateral and several roots are involved. The absence of vasomotor or trophic symptoms in this case spoke against syringomyelia. Differentiation from caries was more difficult, as some of the symptoms suggested it, also the predominance of motor over sensory disturbances, the comparatively rapid involvement of the other side (after six months), and the rigid way in which the head was held. Arguments against caries were found in the lack of any indications of tuberculosis or of a tendency to a hump or to protrusion of the rear wall of the throat, and also the normal temperature during the eight weeks of observation. Roentgen findings were negative. Abrupt pressure of the head in the direction of the spine did not cause the violent pain common to spondylitis, and extension gave no relief. As the highest muscles unmistakably affected with atrophy were the supraspinal, the upper edge of the tumor was supposed to reach the fourth cervical segment at least, possibly also the third and second. This was suggested by the zones of hyperesthesia which reached to the edge of the hair at the back and in front almost to the margin of the lower jaw. In this region the patient also located her most violent pains, although they sometimes extended into the back of the head and to the temples and brow. She also complained of pains in the left middle intercostal spaces, but these were disregarded in the diagnosis. It was assumed that the tumor probably extended downward to the eighth cervical segment, on account of the participation of the smaller muscles of the hand and the eye symptoms. Engravings of the tumor are given in natural size and colors. It was 6.5 cm. long by 1.5 to 2.25 cm. wide and 1 cm. thick, of rather solid consistency. It surrounded the spinal cord like a mantle, and its upper portion lay for 2.5 cm. beneath the atlas and axis. It was only lightly adherent to the arachnoid, and it slipped out from beneath the unopened atlas on gentle traction. Its removal was followed by a gush of blood-stained fluid, but this was soon arrested by lowering the head of the table and tamponing. The tampon was removed in a few minutes, and it was seen that the flattened spinal cord had resumed its cylindrical shape. Seven catgut stitches were taken in the dural sac, and a strip of gauze brought out through the wound which was sutured with catgut in tiers. No symptoms on the part of pulse or respiration were observed during the ablation of the tumor. The patient rapidly recovered, the paralysis and atrophy promptly subsiding; the muscles first affected regained function first. The eye symptoms, however, persisted unmodified. The incision extended from the atlas to the first dorsal vertebra, and the spine was carefully dissected free from the soft parts. When this had

been done, the patient suddenly stopped breathing and the pulse became imperceptible, but both were restored by two minutes of artificial respiration. On account of the necessary manipulations for this, the asepsis of the field was dubious, and consequently the soft parts were held back with a roll of gauze on each side and the skin was sutured over them. Three days later the operation was continued and the removal of the tumor then proved an easy task. Among the conclusions drawn from this experience is the refutation of the assumption that intradural tumors are necessarily small. Also that the injury from the tumor is liable to be felt more seriously in the part of the spinal cord opposite to the tumor than in the part directly contiguous to it. The patient in the present case recovered so completely that her right arm is now stronger than the left, notwithstanding its long paralysis. The operation was undertaken about eleven months after the first symptoms of trouble had been noted. Operating in two sittings was possibly one of the main factors in the success obtained.

63. **Cryoscopy of Blood and Serous Fluids.**—This article by Cohn contains the bibliography of the subject, in addition to extensive personal research. He found the freezing point of normal blood between —0.517 and —0.562 C. He noted that it was frequently abnormally low in chronic nephritis and generally so in uremia and leukemia. In febrile affections it was abnormally high. Contrary to what is observed in animals, inflammatory fluids in the pleura, peritoneum, spinal cord or brain are not isotonic with the blood serum in man. He was unable to find any particular molecular concentration of the blood characteristic for any special kind of nephritis.

64. **Prospects for Early Diagnosis of Intestinal Cancer.**—Boas analyzes his experience and comes to the conclusion that the prospects for early diagnosis of cancer in the intestines and its successful removal are not very promising. The really incipient stage of intestinal cancer is beyond our powers to detect. Early application to a physician and early diagnosis do not guarantee the possibility of its radical removal in all cases, and not even in the majority of gastrointestinal cancers. He cites a number of instances to show further that good results are possible even when the symptoms have long existed. The kind and the malignancy of the tumor are the deciding factors, not the promptness with which the affection is diagnosed after the first symptoms appear. Our very earliest diagnosis, as a rule, is too late. Metastases or ascites are found even in the apparently very earliest stages in a large proportion of cases. He does not believe that gastroscopy will ever acquire much importance, as the very first subjective symptoms are generally found accompanied by advanced objective changes in the majority of cases of intestinal or stomach cancer, even in case of cancers of the rectum which are more accessible than others. Much might be accomplished by better training of physicians in the diagnosis of cancer, and Boas here reiterates his plea for the establishment of cancer-examining stations for suspicious cases. This would reduce the number of investigated but *incorrectly* diagnosed cases of rectal cancer, and also of cancer of the colon. The latter have a better prognosis than cancer elsewhere in the gastrointestinal tract. The malignancy of cancer, he thinks, lies not only in the neoplasm itself, but in the insidious latency of its development.

67. **Idiopathic Osteopsathyrosis.**—Looser reports the results of examination of the amputated leg of a patient with typical congenital imperfect and tardy bone formation. It has convinced him that the condition is a clinically and anatomically well-defined affection, as he relates in detail.

68. **Guaiacol in Treatment of Tuberculosis of the Kidneys.**—Schüller describes two cases of tuberculosis of the kidneys in which he realized a complete cure by internal and local application of guaiacol for months. His first patient was a man of 40, with evidences of apical tuberculosis, bacilli in sputa, bilateral tuberculous processes in the testicles and tubercle bacilli and kidney epithelial cells and red corpuscles in the urine. The process in the testicles healed completely after seven injections of a guaiacol-iodoform-glycerin preparation, combined with internal administration of guaiacol for several months. The drug was then suspended for a few months, and then resumed for a few weeks, by which time no further evidences of tuberculosis in any organ could be detected. The patient has been definitely cured, now for more than thirteen years. Schüller's second patient was a little girl with a tuberculous process in the hip joint and evidences of a tuberculous affection of the kidneys. Guaiacol topically and internally was followed by the cure of the hip process and the subsidence of all symptoms on the part of the urinary apparatus, without recurrence during the nine years since. He consequently suggests the advisability of guaiacol treatment in the incipient stages of tuberculosis of the kidneys and bladder, also after removal of one kidney to protect its mate, and, further, in the cases in which a partial operation has been done on the kidney, in order to hasten and to promote the permanent recovery of the organ. Some of his patients have taken guaiacol for more than four years without inconveniences. He gave it in 200 cases of tuberculosis between 1891 and 1899, and 37 of the patients were materially improved or quite cured by it. The kidneys are especially adapted for this mode of treatment, as part of the guaiacol is eliminated through these organs. His practice is to give it in small fractional doses continually. His dose for adults is from 12 to 15 or even 20 drops of pure guaiacol in from 130 to 150 or 200 gm. of water, shaken until dissolved, and fractioned into five or six portions. Children take from 3 to 23 drops, according to age. No preparation of guaiacol has proved so effectual in his experience as the pure article.

69. **Periarteritis Nodosa.**—Versé has been able to find only 20 cases of this affection in the literature. Men between 20 and 35 were principally affected, but the disease has been observed in an infant under 3 months and in one man of 52. The course is always more or less acute, terminating fatally in three or four months. He describes the history and findings in a typical case personally observed. Signs of old nephritis were found and a peculiar affection of the smaller arteries in the liver, mesentery, intestine, stomach and spermatic cord, characterized by the formation of small spindle-shaped or round aneurisms, with thrombosis of the vessels affected. In 5 of the published cases syphilitic antecedents were certain, and Schmorl has reported one in which the multiple lesions entirely retrogressed under antisyphilitic treatment. At the autopsy years later, the vessels were found normal, but in the liver, kidneys and heart traces of the old affection could be detected in the form of minute fibrous foci closely related to the vessels. Periarteritis nodosa may thus be regarded as a special form of syphilis of the blood vessels.

70. **Nasal Diphtheria with Scarlet Fever.**—Uffenheimer describes a fatal case of what appeared to be diphtheria affecting the nose during the last stages of scarlet fever. He argues that it was not true diphtheria and that the membrane formation was exclusively the work of the scarlet fever infection. He calls the condition nose diphtheroid, with scarlet fever. A very few non-virulent diphtheria bacilli were found in the midst of countless numbers of streptococci.

71. **Treatment of Suppuration in Maxillary Sinus.**—Strubell takes two maxims as his guide: To rinse only so long as the patient tolerates it without objecting, and to reject all radical measures which leave a permanent communication between the mouth and the sinus. He describes his methods and technic in detail.

73. **Cytorrhyctes Luis.**—Freund regards it as very remarkable that the announcement of the discovery of spirochetes in syphilis has attracted such widespread attention, while Siegel's announcement in regard to the finding of the *Cytorrhyctes luis,* at about the same time, has passed almost unnoticed. Freund has confirmed Siegel's findings in nearly a dozen cases of syphilis, and has succeeded in inoculating animals with the cytorrhyctes. He found them in enormous numbers in his cases, corresponding to from 3,000 to 5,000 in a single drop of blood or 60,000,000 in a liter of blood. The extreme contagiousness of syphilis can be explained only by assuming that the causal germs are present in every drop of blood. Siegel's bodies are flagellates, and the blood corpuscles near them sometimes rock a little as if set in motion by the action of the flagella. The stains that show tne spirochetes are the best ones for the cytorrhyctes also, but they can be seen equally well without staining. Siegel's illustrated description appeared in the *Münch. med. Wochft.* for July 11, No. 28, 1905.

81. **Treatment of Gynecologic Affections with Thiosinamin.**—Offergeld gave thiosinamin a thorough trial in 55 cases of various gynecologic affections, but found that it failed to display any power to reduce infiltrations or to soften adhesions or contractures. No benefit whatever was realized in any instance that was not amply explained by the concomitant measures.

86 (No. 32.) *Om Behandling af tuberkulos Peritonitis. C. A. Dethlefsen.

82. **Hyperacidity and Sahli Test Meal.**—Rubow reviews the experiences during the last five years with 704 patients presenting dyspeptic disturbances treated in Faber's service at Copenhagen. Hyperacidity, *after* an Ewald-Boas test meal, was found in 213. The details of these cases with acidity of 75 or over are given in tabulated form. None showed a total acidity above 125. He thinks that this shows the rarity of actual hyperacidity, as all the cases are explainable by simple hypersecretion. The proportion of hydrochloric acid averaged .44 per cent. Only in three instances did it reach .45 and .46 per cent. Trials of the Sahli test meal gave conflicting findings, even in healthy subjects. He thinks that one source of error is in the rising of the butter to the top of the "flour soup" used for the test. It does not form a homogeneous emulsion.

85. **Ether Anesthesia.**—Struckmann argues that a combination of morphin and ether insures an almost ideal anesthesia without by-effects. He uses the Sudeck mask and a dropper for the ether, and emphasizes the remarkable absence of salivation and secretion when from 1 to 1.5 cg. of morphin was injected one hour before the ether. All his surgical patients during the last six months were anesthetized in this way, and the results far surpassed those observed with any other mode of anesthesia. There was no stage of excitement, and the pulse, respiration and color of the face remained normal throughout. He is convinced that this form of anesthesia avoids all the dangers of other technic, and is far more convenient for both the surgeon and the patient.

86. **Tuberculous Peritonitis.**—Dethlefsen relates the history of a girl of 7 with typical tuberculosis of the peritoneum cured by a median laparotomy. Another case was that of a married woman of 40, with other indications of tuberculosis, accompanying those of typical tuberculous peritonitis. The peritoneal process was arrested by a median laparotomy, and the ascites never returned, but the patient succumbed a year or two later to the progress of her lung affection.

87. **Dosage of Antidiphtheria Serum.**—Suber tabulates statistics from various countries to sustain his assumption that antidiphtheritic serum should be given in large doses (5,000 to 15,000 units) in the severer cases of diphtheria, irrespective of age. The moderately severe cases can be treated with moderate doses (3,000 to 4,000 units). Intravenous injection in the extremely severe cases has a prompt and certain curative action, without serious by-effects, even when colossal doses are used. He claims that the published statistics show that insufficient doses have been given in many instances. Injection of large doses of the serum also proves effective even against diphtheritic paralysis. He rejoices that the price of the serum has recently been reduced in Sweden, and urges that all the local boards of health and hospitals should be provided with the serum for preventive injections at need, free of cost.

88. **Postoperative Treatment of Cancer with X-Rays.**—Sjögren is now making a practice of *x*-ray exposure after ablation of a cancer in all cases. He has thus treated 10 patients with mammary cancer and 2 with sarcoma, allowing an interval of from one to three months after the extirpation before he commenced the Roentgen exposures. More than six months have elapsed since the sarcoma operations, and there has been no trace of recurrence in any instance. The first case was a sarcoma in the kidney of a girl of 5, and the other a sarcoma originating in the soft parts of the hip in a woman of 21. He thinks that systematic postoperative *x*-ray treatment, to forestall recurrence, is a most promising field.

92. **Oxidizing Ferment as Cause of Green Stools of Infants.**—Wernstedt calls attention to the fact that green stools are distinguished not only by their color, but by the presence of considerable mucus. He thinks it is due to the action of a substance which he has isolated from such stools, and regards as a ferment. It oxidizes guaiacol in presence of hydrogen dioxid, but the reaction does not occur if the stool is first heated to boiling point. The oxidation causes a brownish discoloration which is most marked in the flakes of mucus and is not diffuse. The substance is contained in the mucus and apparently has an oxidizing action on bilirubin. Green stools do not necessarily imply dyspepsia, he says, but may be observed in starving infants and occasionally in those apparently otherwise healthy.

THE INFLUENCE OF CHRONIC PASSIVE CONGESTION AND CIRRHOSIS OF THE LIVER ON THE CONNECTIVE TISSUES OF THE SPLEEN.*

HENRY A. CHRISTIAN, M.D.
Instructor in Pathology and George Cheyne Shattuck Fellow Harvard Medical School; Assistant Visiting Pathologist, Boston City Hospital; Assistant Visiting Physician, Long Island Hospital.
BOSTON.

It is well known that in cases of cardiac disease which have caused chronic passive congestion of the abdominal viscera the spleen is usually firmer than normal, unless some complicating acute infectious process has produced an acute splenic tumor. Similarly with cirrhosis of the liver there is generally a firm spleen. In either case the spleen may or may not be larger than normal.

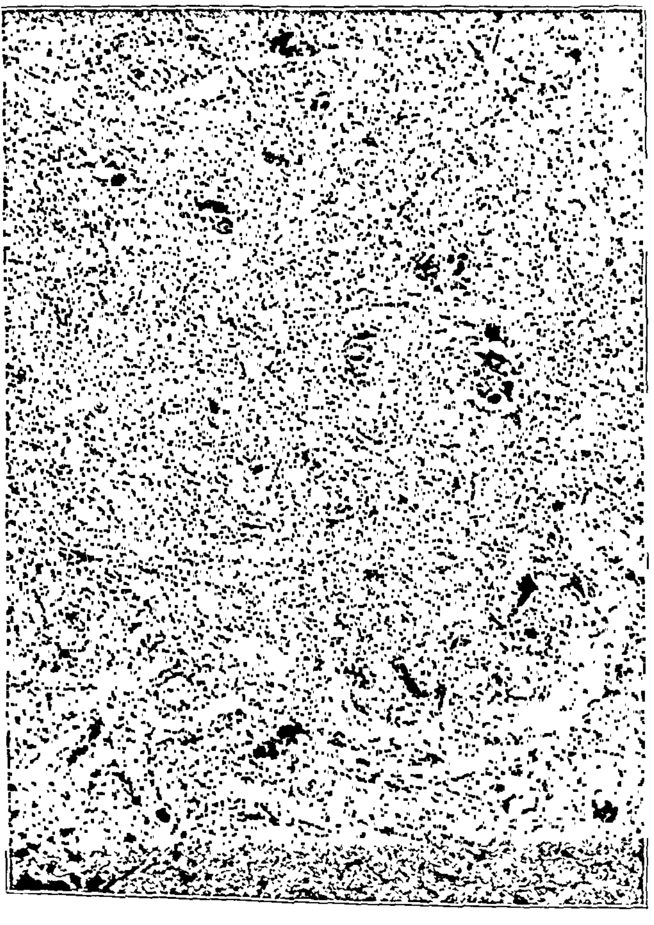

Fig. 1.—Chronic passive congestion. Spleen showing connective tissue increase (x 120 dia.).

The following questions arise in regard to the spleen under these conditions: With this increase in consistence is there an increase in the framework of the spleen? Is the change in the white fibrous and reticular tissue or in the elastic tissue? Is there any difference in the character and distribution of the connective tissues of the spleen in cases with chronic passive congestion or cirrhosis of the liver?

It was thought that these questions might be answered by the study of a series of such cases selected from the autopsy material at the Boston City Hospital since 1901. To be regarded as suitable for this purpose cases had to fulfill the following conditions: The patients must be adults; the autopsies must be made soon enough after death to furnish tissue in good condition for the staining methods used; the cases must be free from infectious processes leading to the production of an acute splenic tumor; and, finally, histologic examination of the liver must show well-marked lesions of chronic passive congestion or cirrhosis. Among 891 cases examined, 38 fulfilled these conditions. From them Zenker-fixed material was imbedded in paraffin, sec-

tioned, and stained with eosin and methylene blue, Mallory's anilin blue connective tissue stain, and Weigert's resorcin-fuchsin elastic tissue stain.*

In the 38 cases selected the livers show either well-marked cirrhosis of the multilobular or monolobular type (atrophic or Laennec's cirrhosis), or chronic passive congestion of an advanced degree. In the latter the central one-third to one-half of the liver lobule is congested with marked atrophy or total disappearance of liver cells. Fibrin thrombi occur frequently in the sinusoids, but do not dominate the picture in any case. In five cases the connective tissue about the central vein is increased in amount (moderate central cirrhosis. Of the cases of cirrhosis none shows a diffuse intralobular distribution of connective tissue (hypertrophic or Hanot's cirrhosis).

In the spleens no lesions of the Malpighian corpuscles occur, though there is some variation in their size. The pulp of the spleen in all cases is relatively poor in cells. The blood sinuses are generally dilated, distinctly demarcated, and usually are lined by a definite layer of low cuboidal endothelial cells. Between the blood sinuses lies a tissue made up of cells of the connective tissue and endothelial types, with a varying number of, rarely many, lymphoid and plasma cells and an occasional leucocyte. Sections with little or no connective tissue increase, as a rule, do not show the sharp distinction between blood sinuses and intervening cellular tissue, and here cells of the connective tissue type are not so prominent.

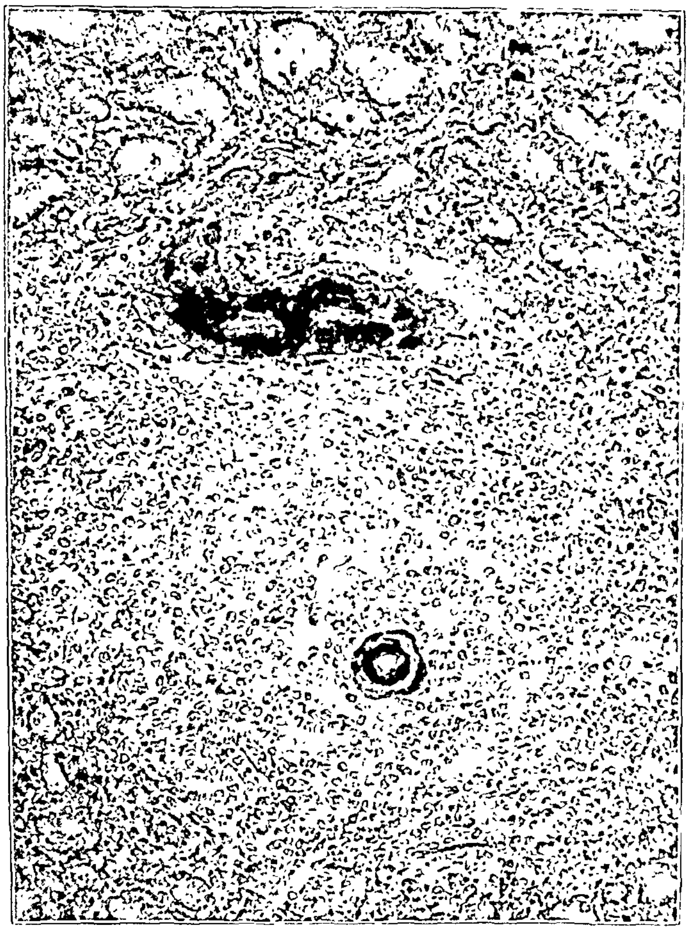

Fig. 3.—Chronic passive congestion. Spleen showing absence of connective tissue increase in Malpighian corpuscle.

The anilin blue connective tissue method stains white fibrous and reticular tissue blue, but does not tinctorically distinguish the two. In the spleen the trabeculæ and walls of larger blood vessels contain white fibrous tissue appearing as bundles of straight or slightly wavy fibrils. Outside of this the supporting framework consists mainly of recticulum, a meshwork of blue-staining fibrils, slight in amount in the Malpighian corpuscles, more abundant in the pulp between the blood sinuses. About the blood sinuses are circular fibrils staining blue, which surround them at very regular intervals.

In the group of 38 cases studied, the white fibrous tissue of trabeculæ and blood vessels presents little or no change. In 10 cases the reticulum is not increased; in 28 it is present in increased amount. As seen in the table, the latter are divided into three groups; nine with considerable, eleven with moderate and eight with slight increase. Both the size and the number of the fibrils is increased.

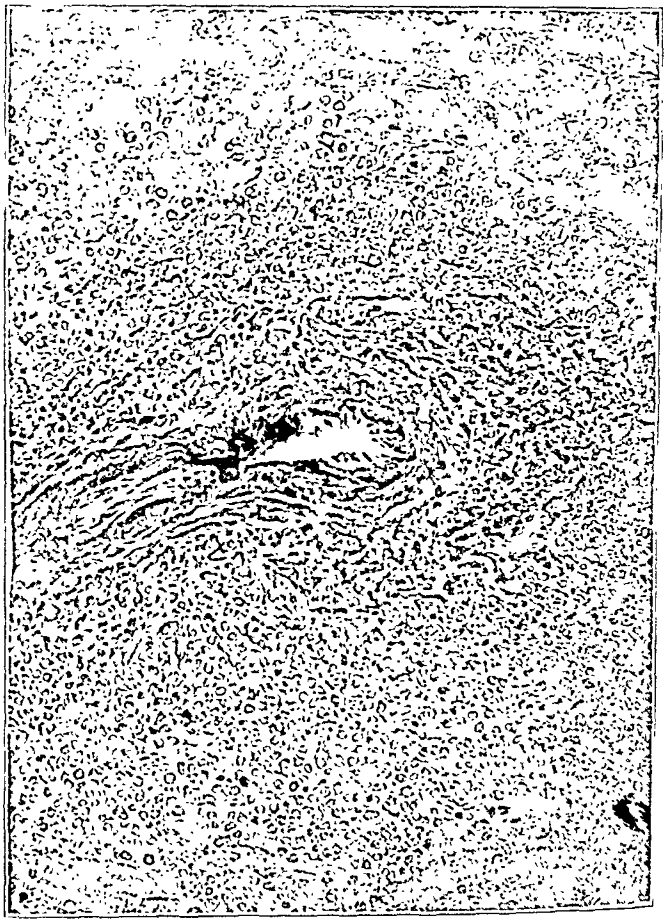

Fig. 4.—Cirrhosis of Liver. Spleen showing connective tissue increase about artery within Malpighian corpuscle.

In the cases of chronic passive congestion, the reticulum of the pulp is increased (Figs. 1 and 2), and there is little change within the Malpighian corpuscles (Fig. 3). In the cirrhosis cases there is a similar increase in pulp reticulum, to which is added an increase about the smaller splenic arteries and within the Malpighian corpuscles (Fig. 4), in cases in which there is a more marked connective tissue increase.

The increase in reticulum is sufficient to explain in part the increased firmness of the spleen under these conditions. The slight difference in its distribution in chronic passive congestion and cirrhosis may add some weight to the view that the changes in the spleen accompanying cirrhosis of the liver are only in part due to simple mechanical hindrance to its circulation.

The elastic tissue in the 38 cases, as demonstrated by the Weigert resorcin-fuchsin method, shows very little change. Elastic tissue is present in the spleen in the capsule and trabeculæ in large amount, and also occurs in the walls of larger blood vessels, and to a slight degree extends from them out into the surrounding splenic tissue. Outside of these places practically none is found, though with overstaining, certain fibers about the sinuses are deeply tinted. However, careful differentiation with absolute alcohol separates these from the typically staining elastic tissue fibers. In a few cases there is a slight increase in the elastic tissue radiating from the blood vessels, but there is no difference in this respect between chronic passive congestion and cirrhosis cases.

38	75	Firm	1,510	Chr. passive congestion.

SUMMARY.

1. In 38 cases of chronic passive congestion and cirrhosis of the liver, the spleen of 28 (73.6 per cent.) shows an increase in connective tissue framework. Some of the 10 cases with no increase in connective tissue are equally as firm; consequently the firm consistence in these is due to vascular distention rather than to connective tissue increase, and in all cases vascular distention probably plays an important part in producing the firm consistence.

2. The connective tissue increase is mainly a proliferation of the reticular tissue of the pulp with little or no change in the white fibrous and elastic tissue of the organ.

3. Some cases of cirrhosis show in addition to the proliferation in pulp reticulum, an increase in connective tissue about the smaller splenic arteries and within the Malpighian corpuscles.

ETIOLOGY OF PIGMENTOUS SARCOMA OF THE CHOROID.*

PROF. J. HIRSCHBERG.
BERLIN.

The cause of malignant tumors generally, and of the pigmentous sarcoma of the choroid especially, is a mystery to us. It is impossible to find one general cause for all of them. The reason, in my opinion, is that there are different causes in existence for different forms of the disease.

In 1882, I observed and published reports of two cases in which the monolateral congenital pigmentation formed the predisposition to the development of a melanotic sarcoma of the choroid.

The color of the iris in the healthy eye was grayish green; in the other dark brown, and the sclerotica of the dark eye contained around the cornea some large dark violent spots which were congenital according to the decided assertions of the patient.

In the one case, the eyeball was enucleated at once and showed a pigmentous sarcoma of the choroid. The melanoid spots of the sclerotica extended over the equator to the entrance of the optic nerve. They were composed of stretched but normal pigment cells.

In the other case, the affected eyeball had yet a tolerably good vision. Excision was performed two years later, as the vision had gone; seven years later the patient was in good health; nine years after excision death occurred, probably by metastasis.

In another group of cases, a congenital pigment spot in the iris was the cause of a pigmentous sarcoma of the same coat. I had two cases—one in the year 1868, in which excision of the eyeball was performed by my teacher, Albrecht von Graefe. I published a report[1] of the case in the *Archiv. f. Ophth.*, xiv, 3, 1868; it was the first case of melanotic sarcoma of the iris.

I observed the other patient in the year 1894, and operated by iridectomy. The microscope showed sarcoma. After nine years the patient was observed in perfect health, the eyeball blind, but quiet. The report of the case was published by my assistant, Dr. Fehr, last year, in the jubilee volume presented to me.

The third fact is a circumscribed pigment spot in the iris, causing a melanotic sarcoma in the same region of the ciliary body of the affected eyeball. This case is a new one, which I will now describe with some details:

Patient.—A woman, aged 33, presented herself May 2, 1905, with a letter stating that she was suffering from detachment of the retina of the right eye. Seven months previously she had observed that the eye was almost blind.

Examination.—I found the left eye entirely normal. The right one had only a very small eccentric visual field below the fixation point, and could only distinguish the finger at a distance of 35 cm. This eye was free of irritation and hypertension, but showed in the lateral octant of the greenish iris a large yellow-brown spot of trapezoid form, occupying the whole extent of the iris breadth. This spot was congenital, or at least noticed from the first childhood of the patient. Immediately behind the iris, in the same part of the eyeball, to the temporal side, a tumor was visible even by the naked eye of the observer. With focal illumination and the loop I detected a reddish-yellow sarcoma of that region with fine vessels on the surface and some pigment spots. Below the lens there was a dark neoplastic nodule. With the

[1] Before my report only a single case of that had been mentioned, but not discussed by Hulke, 1861, vol. iii, p. 280, Ophth. Reports Fr., "Sarcom der Uveal Tractus," 1882, p. 234, has a short remark about that subject, but the cases of Warren, Tay and Kipp, which he mentions, *do not belong to this class.*

ophthalmoscope the optic nerve entrance was visible, and very near to it a detachment of the retina.

Treatment.—As the diagnosis was self-evident, I proposed excision and performed it six days later, the home physicians of the patient having approved of my diagnosis and of the proposed treatment. A fortnight later the patient was discharged.

Pathologic Examination of Eyeball.—Now I come to the anatomic examination of the excised eyeball. The eyeball is

the size of a cherry appear

in the lower half of the globe, one-quarter in the upper half. The cut surface is rather bright and shows several sections of blood vessels or spaces. The lower part of the tumor is not visible in this section, but it appears in a second horizontal division of the lower half of the globe. The tumor starts from the outer lower part of the ciliary body which here is thickened and converted into neoplasm. The middle part of the tumor is firmly adherent to the detached retina; between its posterior part and the retina there is an exudation coagulated by formol. The tumor is a sarcoma made up of small, round and spindle cells, the round cells prevailing; it is poor in pigment and rich in large vascular spaces with only capillary coats. Interstitial tissue is scanty. A fine connective coat surrounds the tumor and adheres to the retina, which also is converted into connective tissue.

In sections which correspond to the width of the pupil, as seen in Figure 2, the neoplasm is separated from its base or foot, but the ciliary body is thickened and interspersed with sarcomatous cells. Such cells are also visible in the wall and in the lumen of the canal of Schlemm.

The iris of the lateral half corresponding to the tumor is intensely pigmented. The yellow-brown pigment is situated in the superficial layer of the stroma, partially extracellular, partially in ramified chromatophore cells. The iris of the opposite side is free of pigment in the whole stroma and contains only the posterior pigment layer.

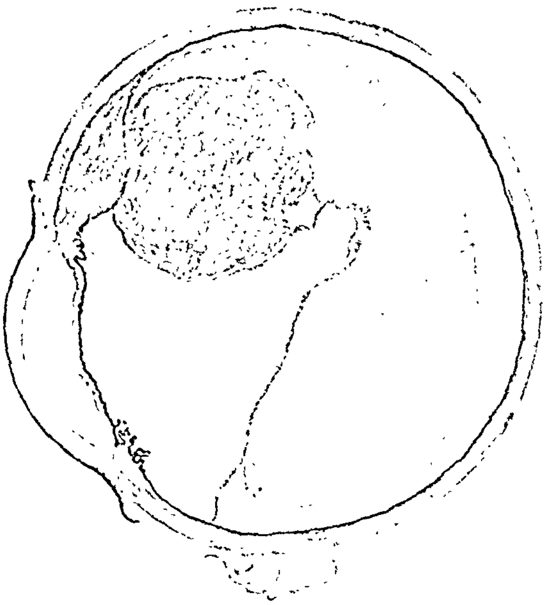

Figure 3.

In the sections which approach to the lower pupillary margin the tumor gradually becomes in touch with the ciliary body (Fig. 3).

In the lower part of the lower half of the globe the whole ciliary body is converted into neoplasm to the root of the iris. This tumor of the ciliary body is spindle-shaped and its upper border perforates the boundary coat and grows freely and fungiform into the subretinal space.

For the microscopic preparations and the able drawings, I am indebted to my first assistant, Dr. Fehr.

We must agree that the tumor started from this part
ciliary body which corresponds to the congenital

A CASE OF MELANOSARCOMA OF THE CHOROID.*

LEWIS H. TAYLOR, M.D.,
WILKESBARRE, PA.

I wish to report briefly a case of melanosarcoma of the choroid occurring in my practice, because of some of the interesting features connected therewith and the later metastasis to the liver and the death of the patient:

Patient.—Mrs. B, aged about 65, was first seen by me in consultation with her family physician Dec. 22, 1900. The patient was in bed suffering great pain with the left eye, which was much swollen and congested.

History.—Four days previously, in the early hours of the morning, her left eye became suddenly affected with very severe pressing pain. Her physician saw her at the time and during the following forenoon the severe pain passed away, but the eye remained uncomfortable and the sight was gone. The eye was not swollen but looked much the same as the other. When first seen by me it was greatly swollen, tension increased, the iris pushed forward, and the cornea steamy. Her physician had used atropia three times. This was discontinued as the eye was in complete condition of absolute glaucoma, from, as I supposed, intraocular hemorrhage. I changed to eserin. There was also some chemosis of the conjunctiva. Lead water and laudanum lotion was applied. On the following day the eye was more comfortable but very rigid, almost suggestive of panophthalmitis.

December 24 the condition was about the same but she had passed a comfortable night; three leeches had been applied. I went away for Christmas and returned late on December 26. On the 27th the condition had not improved, and I informed her husband and the family physician that, in my judgment, the eye should be enucleated at once, or within a very few days and suggested consultation.

The patient had had trouble with this eye three months before, in September, and came to my office during the meeting of the Pennsylvania State Medical Society and as I was not in she went to another oculist, who treated her a while with improvement and fitted her with glasses. Later she went to Philadelphia on a visit and while there was treated by Dr. J. T. Carpenter, who in reply to a letter of inquiry wrote me December 26 as follows:

"I saw Mrs. B. November 15, 1900, and her condition at that time was as follows: O. S. V. = fingers in limited area of temporal field. External appearance normal; tension normal. History of sudden blindness preceded by intensely brilliant phosphenes. Eye shows extensive retinal detachment, balloon-shaped, occupying almost the entire fundus with a narrow area in central upper nasal quadrant where retina is still attached and fundus appears normal. No tremulousness of retinal detached area on ocular movement. The normal portion of the retina shows refraction to be about Em. or low H. I could not make out the exact nature of the case but in absence of myopia considered the possibility of its being retinal separation of intraocular growth in the quiet stage. The possibility of an enormous retinal hemorrhage was also considered."

Operation.—At my request Dr. Carpenter came for consultation December 28, as did also Dr. Gloniger of Lebanon, Pa., a relative of the family. Both agreed with my expressed opinion that the eye should be enucleated. This I did at once, suturing the conjunctiva in the usual manner. On the following day there was no discharge but considerable swelling. I had probably closed the wound a little tighter than necessary. Under daily dressing this soon subsided and the wound healed kindly without any trouble.

Examination of Eye.—Dr. Carpenter took the eye to Philadelphia for examination and made a preliminary report January 5 as follows: "There is a heavily pigmented mass in the choroid which is very decidedly like sarcoma." Later he wrote: "The microscopic examination makes the diagnosis of the choroid only too evident. I have submitted the sections to Dr. Edward Shumway, who reports as follows:

"*Macroscopically.*—A densely pigmented mass found springing from the choroid, 12 mm. in height and 10 mm. in diameter at base. The retina is completely detached, the lens pushed forward, the subretinal space filled with albuminous exudate.

"*Microscopically.*—A densely pigmented mass found springing from the larger vessels of the choroid. Pigmented cells make up the main bulk of the tumor, they are round and spindle-shaped, the surface layers are infiltrated with blood, and the blood vessels of the growth are widely distended. The choroidal vessels, in common with the central retinal vessels and the posterior ciliary vessels show great thickening of walls, involving both adventitia and intima, the endothelial cells of the latter much proliferated. No structure is discernible in the retina which shows no connection with the choroid at the ora serrata. It is probable that the detachment is not of recent date. The optic nerve was found infiltrated with sarcoma cells which stain better than in the tumor itself. A large recent hemorrhage with corpuscles staining well is found beneath the retina and in the tumor itself.

"*Summary of Findings.*—Large densely pigmented sarcoma of the choroid showing extensive degenerative changes; detachment and degeneration of the retina; sarcomatous infiltration; and destruction of the optic nerve; intraocular hemorrhages; secondary glaucoma; cataract and pressure necrosis of iris, ciliary bodies and cornea."

Subsequent History.—This report naturally made us fear an early return of the trouble and gave a very unpromising outlook for the patient, as the experience of others would lead one to expect a return either in situ or in some other organ within a year. In spite of the infiltration of the optic nerve, there was no return of any growth in the orbit. The patient seemed to recover fully her general health, and during the rest of the winter and spring was very well.

I saw her a number of times and fitted the right eye with distance and near glasses, and she could read comfortably. She was somewhat nervous about the right eye, fearing it might also become affected, but it gave her no trouble. She went away during the summer and was fairly well, returned in the fall, and soon after noticed trouble in her right side. This progressed rapidly and she died of sarcoma of the liver Nov. 15, 1901. The orbit remained entirely free from any return of the sarcoma.

It is rather rare to have occasion to see and to diagnose a case of pigmented sarcoma of the choroid and afterward to confirm the diagnosis by microscopic examination. And yet a number of such have been reported. Frequently, as in the case above reported, the diagnosis is not made until the eye has been enucleated on account of hemorrhagic glaucoma. As to the return, the time varies greatly, but as stated above, it is likely to return either in the orbit or by metastasis to some other organ within a year or two.

Dr. Buller of Montreal reported a case to the American Ophthalmological Society some years ago of a return *in situ* after ten years. A very interesting summary of the subject of sarcoma of the choroid may be found in the Ophthalmic Year Book for 1905, by Drs. Jackson and de Schweinitz, who close by reference to Professor Hirschberg's work thus:

> The most important contribution of the year to the question of recurrence in loco and metastasis after enucleation for choroidal sarcoma is by Professor Hirschberg. He records the statistics of 68 cases of sarcoma of the uveal tract seen between the year 1872 and 1903; of these 63 were in the choroid. Sixty-six enucleations were performed. There were no deaths from the primary operation. Local recurrence was observed only once, in which perforation had occurred before enucleation. In two out of six cases in which puncture of the eyeball for diagnosis was made previous to operation, there was a recurrence in the position of the conjunctival puncture, so that he advises against this procedure. Death occurred from metastasis in 16 cases, in 12 of these within two years. Of 41 cases that could be properly followed, one died from local recurrence, 2.5 per cent; 17 from metastasis, 41.5 per

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

ophthalmoscope the optic nerve entrance was visible, and very near to it a detachment of the retina.

Treatment.—As the diagnosis was self-evident, I proposed excision and performed it six days later, the home physicians of the patient having approved of my diagnosis and of the proposed treatment. A fortnight later the patient was discharged.

Pathologic Examination of Eyeball.—Now I come to the anatomic examination of the excised eyeball. The eyeball is divided by a horizontal section into an upper and a lower half. Figure 1 shows the lower half. Cornea, anterior chamber and lens seem normal. The iris stroma is bright in the nasal side, broader and brown in temporal side. The retina is completely detached. In the subretinal space a tumor of the size of a cherry appears, three-quarters of it being located in the lower half of the globe, one-quarter in the upper half. The cut surface is rather bright and shows several sections of blood vessels or spaces. The lower part of the tumor is not visible in this section, but it appears in a second horizontal division of the lower half of the globe. The tumor starts from the outer lower part of the ciliary body which here is thickened and converted into neoplasm. The middle part of the tumor is firmly adherent to the detached retina; between its posterior part and the retina there is an exudation coagulated by formol. The tumor is a sarcoma made up of small, round and spindle cells, the round cells prevailing; it is poor in pigment and rich in large vascular spaces with only capillary coats. Interstitial tissue is scanty. A fine connective coat surrounds the tumor and adheres to the retina, which also is converted into connective tissue.

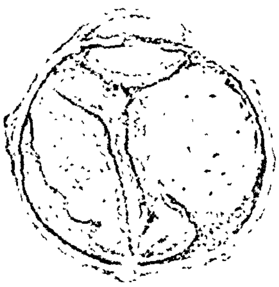

Figure 1.

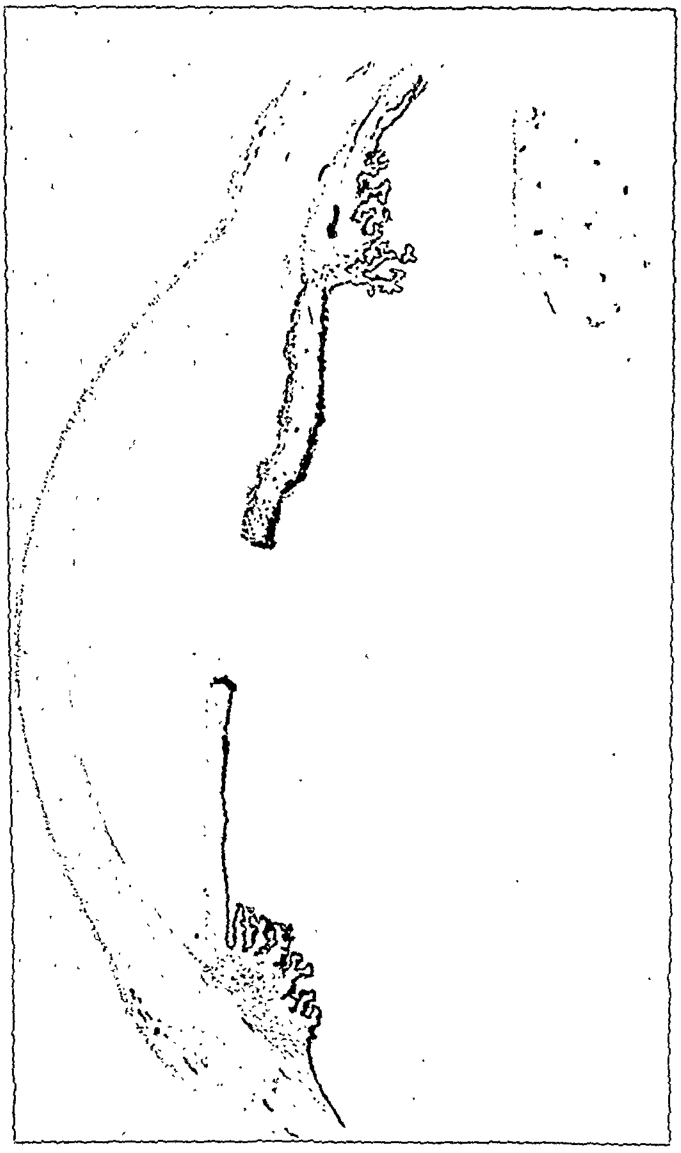

Figure 2.

In sections which correspond to the width of the pupil, as seen in Figure 2, the neoplasm is separated from its base or foot, but the ciliary body is thickened and interspersed with sarcomatous cells. Such cells are also visible in the wall and in the lumen of the canal of Schlemm.

The iris of the lateral half corresponding to the tumor is intensely pigmented. The yellow-brown pigment is situated in the superficial layer of the stroma, partially extracellular, partially in ramified chromatophore cells. The iris of the opposite side is free of pigment in the whole stroma and contains only the posterior pigment layer.

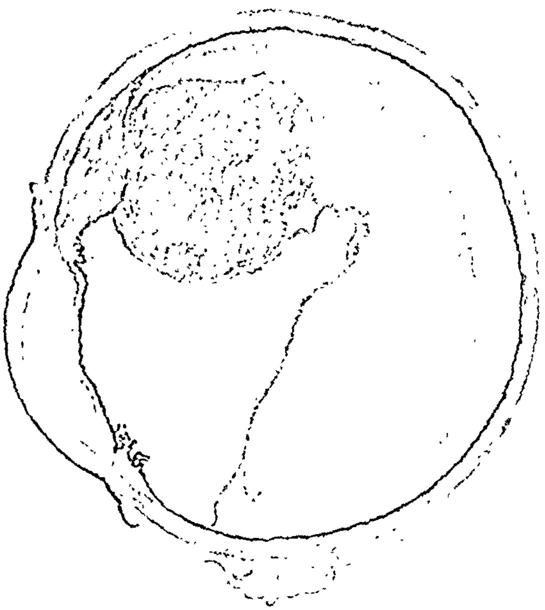

Figure 3.

In the sections which approach to the lower pupillary margin the tumor gradually becomes in touch with the ciliary body (Fig. 3).

In the lower part of the lower half of the globe the whole ciliary body is converted into neoplasm to the root of the iris. This tumor of the ciliary body is spindle-shaped and its upper border perforates the boundary coat and grows freely and fungiform into the subretinal space.

For the microscopic preparations and the able drawings, I am indebted to my first assistant, Dr. Fehr.

We must agree that the tumor started from this part of the ciliary body which corresponds to the congenital nevus of the iris.

These facts are very striking; they are not mentioned in the very large and new book of F. Lagrange on tumors of the eye, but they agree with some other facts of the pathology, for instance, that congenital pigment nevi of the cutis, as life advances, are converted into melanotic tumors, and with the theory of Cohnheim that congenital peculiarities of cell groups or persistencies of embryonal germs constitute the real predisposition to later development of malignant tumors.

A CASE OF MELANOSARCOMA OF THE CHOROID.*

LEWIS H. TAYLOR, M.D.,
WILKESBARRE, PA.

I wish to report briefly a case of melanosarcoma of the choroid occurring in my practice, because of some of the interesting features connected therewith and the later metastasis to the liver and the death of the patient:

Patient.—Mrs. B, aged about 65, was first seen by me in consultation with her family physician Dec. 22, 1900. The patient was in bed suffering great pain with the left eye, which was much swollen and congested.

Both agreed with my expressed opinion that the eye should be enucleated. This I did at once, suturing the conjunctiva in the usual manner. On the following day there was no discharge but considerable swelling. I had probably closed the wound a little tighter than necessary. Under daily dressing this soon subsided and the wound healed kindly without any trouble.

Examination of Eye.—Dr. Carpenter took the eye to Philadelphia for examination and made a preliminary report January 5 as follows: "There is a heavily pigmented mass in the choroid which is very decidedly like sarcoma." Later he wrote: "The microscopic examination makes the diagnosis of the choroid only too evident. I have submitted the sections to Dr. Edward Shumway, who reports as follows:

"*Macroscopically.*—A densely pigmented mass found springing from the choroid, 12 mm. in height and 10 mm. in diameter at base. The retina is completely detached, the lens pushed forward, the subretinal space filled with albuminous exudate.

"*Microscopically.*—A densely pigmented mass found springing from the larger vessels of the choroid. Pigmented cells make up the main bulk of the tumor, they are round and spindle-shaped, the surface layers are infiltrated with blood, and the blood vessels of the growth are widely distended. The choroidal vessels, in common with the central retinal vessels and the posterior ciliary vessels show great thickening of walls, involving both adventitia and intima, the endothelial cells of the latter much proliferated. No structure is discernible in the retina which shows no connection with the choroid at the ora serrata. It is probable that the detachment is not of recent date. The optic nerve was found infiltrated with sarcoma cells which stain better than in the tumor itself. A large recent hemorrhage with corpuscles staining well is found beneath the retina and in the tumor itself.

"*Summary of Findings.*—Large densely pigmented sarcoma of the choroid showing extensive degenerative changes; detachment and degeneration of the retina; sarcomatous infiltration; and destruction of the optic nerve; intraocular hemorrhages; secondary glaucoma; cataract and pressure necrosis of iris, ciliary bodies and cornea."

Subsequent History.—This report naturally made us fear an early return of the trouble and gave a very unpromising outlook for the patient, as the experience of others would lead one to expect a return either in situ or in some other organ within a year. In spite of the infiltration of the optic nerve, there was no return of any growth in the orbit. The patient seemed to recover fully her general health, and during the rest of the winter and spring was very well.

I saw her a number of times and fitted the right eye with distance and near glasses, and she could read comfortably. She was somewhat nervous about the right eye, fearing it might also become affected, but it gave her no trouble. She went away during the summer and was fairly well, returned in the fall, and soon after noticed trouble in her right side. This progressed rapidly and she died of sarcoma of the liver Nov. 15, 1901. The orbit remained entirely free from any return of the sarcoma.

It is rather rare to have occasion to see and to diagnose a case of pigmented sarcoma of the choroid and afterward to confirm the diagnosis by microscopic examination. And yet a number of such have been reported. Frequently, as in the case above reported, the diagnosis is not made until the eye has been enucleated on account of hemorrhagic glaucoma. As to the return, the time varies greatly, but as stated above, it is likely to return either in the orbit or by metastasis to some other organ within a year or two.

Dr. Buller of Montreal reported a case to the American Ophthalmological Society some years ago of a return *in situ* after ten years. A very interesting summary of the subject of sarcoma of the choroid may be found in the Ophthalmic Year Book for 1905, by Drs. Jackson and de Schweinitz, who close by reference to Professor Hirschberg's work thus:

> The most important contribution of the year to the question of recurrence in loco and metastasis after enucleation for choroidal sarcoma is by Professor Hirschberg. He records the statistics of 68 cases of sarcoma of the uveal tract seen between the year 1872 and 1903; of these 63 were in the choroid. Sixty-six enucleations were performed. There were no deaths from the primary operation. Local recurrence was observed only once, in which perforation had occurred before enucleation. In two out of six cases in which puncture of the eyeball for diagnosis was made previous to operation, there was a recurrence in the position of the conjunctival puncture, so that he advises against this procedure. Death occurred from metastasis in 16 cases, in 12 of these within two years. Of 41 cases that could be properly followed, one died from local recurrence, 2.5 per cent; 17 from metastasis, 41.5 per

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

cent.; and 23 remained healthy, 56 per cent. This is the best record of success thus far published. Of 47 cases in which anatomic examination was recorded, 35 were melanotic, 9 slightly pigmented, and 2 leucosarcomatous. He reports, finally, a case of metastasis to the liver nine years after enucleation of the eye ball, but considers this very exceptional, and believes that patients who remain healthy after four years should be considered permanently cured.

DISCUSSION

ON PAPERS OF DRS. TAYLOR AND HIRSCHBERG.

Dr. Dudley S. Reynolds, Louisville, said that the chief point of interest, to his mind, is the time which may elapse after operation and recurrence of the disease. He recalled reporting a case of tumor of the iris to the International Medical Congress of 1876, at Philadelphia. In that case the neoplasm, being small, was removed by iridectomy. The patient had gone fourteen years after operation without any trouble whatever, until 1890, when he suffered from overwork, and then the eye became sensitive to light. In 1904 Dr. Reynolds saw this patient again, with the eye presenting an enormous mass, as large as the doubled fist, and the whole orbit and its contents, the lid, brow and part of the cheek, were all incorporated in the mass. He declined to do anything and the patient fell into the hands of a general surgeon, who scraped out the cavity of the orbit, and for five or six months the patient was going about, when suddenly he was seized with pneumonia and died. Postmortem showed that the liver, stomach and lungs had all fused together in one mass. This is an instance in which twenty-eight years elapsed before the fatal issue came. There are other similar cases in Dr. Reynolds' experience, and some in which but a few months elapsed. In the case of a child, ophthalmoscopic examination showed detachment of the retina, of circumscribed form, and the eye becoming painful, it was enucleated. Four months later the child came back with a malignant sarcoma, beginning above the brow and extending to the angle of the jaw. The case terminated fatally in a few weeks.

Dr. John E. Weeks, New York, for facilitating the diagnosis of these intraorbital tumors, commended the lamp devised by Sachs of Vienna. All ophthalmologists have experienced the difficulty of determining the presence of a growth in the interior of the eye. With this lamp of Sachs the eye which does not contain a neoplasm or large foreign body can be transilluminated. The lamp may also be used for direct illumination and a retina that is so opaque that one can not see through it with the ophthalmoscope will be rendered transparent by this means. Dr. Weeks has recently experienced this difficulty in seeing an intraorbital tumor which came out clearly on use of the lamp. He thinks that the origin of the malignant sarcomata from pigmented nevi of the iris has been recognized for some time. It is very probable that sarcoma of the choroid, like sarcoma of the iris, develops in many cases from similar congenital pigmented spots in the choroid.

Dr. Kaspar Pischel, San Francisco, showed specimens of [illegible] of the choroid. One patient he had under observa n for four years refused operation until acute glaucoma th intense pain compelled him to have something done.

Dr. L. H. Taylor said that he had no opportunity of examining his patient with the ophthalmoscope. He confirmed what Dr. Weeks said about the value of the Sachs lamp. He has one and uses it all the time.

Prof. J. Hirschberg said that he has had good results with the Roentgen light in showing a tumor of the choroid in a particularly non-transparent eyeball.

Thoroughness should be vindicated in the work to which we have been called and by which we have to be judged. If we play a game, let us strive to play it well, and not be a "footy"; if we undertake a piece of work, let us finish it to the last jot and tittle. If we profess a subject of knowledge, let us have it at our finger ends. . . . There is honor for the man who can be trusted to the end and whose work does not need to be done over again, who can always be found in his own place, and will always do what is expected of him. There is continual dishonor for the person who is slipshod and unreliable, and fickle and lazy, for he is like the reed which pierces the hand that leans on it.—Ian Maclaren in "Homely Virtues."

SOME OBSERVATIONS ON TREATMENT OF YELLOW FEVER.

L. SEXTON, M.D.

NEW ORLEANS.

While prophylaxis is the step most important to any community threatened with yellow fever, we must do something for the patient who already has the disease, and, to those inexperienced in the management of cases, this is really the most interesting viewpoint of the subject. All that we can do in some cases often comes to naught, as in patients who seem to be overwhelmed by the virulence of the poison from the very start, with marked congestion in the algid condition, which may soon be followed by anuria, feeble, rapid pulse and death. There is also another class of cases in which, either from the small amount of poison injected by the mosquito into the patient, or the splendid eliminating powers of the organs, the toxin seems to be thrown off with such rapidity that it is hardly necessary to aid Nature in the fight. These two opposite conditions in patients have produced a school of therapeutic nihilists in the treatment of yellow fever, which is very much to be regretted, because, for the patient occupying the middle ground between the two extremes just mentioned, there is a great deal to be done to conduct him to a comfortable and safe recovery.

In treating yellow-fever subjects, the constitution of the patient has a great deal to do with the plan pursued. For instance, the plethoric, strong-bodied young person with high fever may take with benefit one 5-grain dose of acetanilid or phenacetin and may use ice caps to back and front of head; whereas for a delicate or weak subject, or one in the algid stage, we who treat yellow fever in New Orleans would not allow even one dose of any of the coal tar derivatives or any ice application whatsoever. The majority of physicians advise against the use of any of the coal-tar derivatives in the treatment of yellow fever. We agree with this treatment for patients with weak hearts, but in the robust, plethoric cases mentioned above, with a temperature of 106 F. maintained for some time, it is more damaging to the patient than would be a single dose of acetanilid or phenacetin, which not only reduces the fever, but quiets the backache and headache, which is characteristic of this fever.

THE HOT BATH.

As a rule, we prefer the hot foot bath treatment, of one hour duration following the initial chill. During the bath the patient is to be snugly covered with light blankets to retain the steam arising from the hot water; and, to encourage the elimination by the skin, hot toweling, with hot drinks and alcohol rubs, should follow the bath to keep the pores of the skin open. If the majority of the physicians who have had experience were asked to state their preference, between the hot and the cold treatment of yellow fever, a great many would say that they prefer the hot method. The hot foot bath has become so universally recognized in tropical climates that we usually find this part of the treatment under way on our first visit to a yellow-fever case. Perspiration may be often augmented by hot lemonade, orange leaf or other tea, which, in addition to increasing perspiration, exerts a stimulating action on the kidneys, which is so much to be desired in treating yellow-fever subjects. In a hot climate, in the midst of summer with a temperature of 105 F., a hot mustard foot bath with warm blankets and still warmer drinks, is not a position to covet, but in its final results or benefit to the patient, it has been found to be more efficacious than the experience with Kibbie and his ice cot. In fact, the only three ways in which ice is to be used in the treatment of yellow fever are in crushed ice to allay vomiting and to quench the thirst; ice bags under and on the head in hot fever and on the stomach to allay vomiting where hemorrhage is suspected. When used on the stomach several folds of flannel intervening prevent the chilling and absorb the moisture from the ice bag.

TREATMENT OF BOWELS.

Elimination by the bowels is just as important as that by the skin, so it is in order to begin the treatment by an agreeable saline cathartic, such as citrate of magnesia, Seidlitz or any effervescing agreeable salts to suit the patient's taste, as we do not wish to disturb or unsettle the stomach at this time. Many physicians prefer an initial dose of calomel and soda, 2½ grains each, followed by some purgative mineral water; this calomel treatment is best suited to subjects who are naturally bilious. Quick flushing of the bowels is what is required, so an enema, or glycerin suppository is ordered if there is any tardy action of the bowels. This flushing must be kept up by enemas, or suppositories daily, as there is a great tendency to the formation of gas in the bowels in all yellow-fever patients. The proper initial purge to be used depends largely on the patient; equally good results seem to have been obtained from calomel in one or broken doses, and from the different saline purgatives rendered agreeable, as no nauseating drug or pills should ever be given to add fuel to the smoldering inflammation already in the stomach, hence citrate of magnesia, the effervescent salts of phosphate of sodium, the charged saline mineral waters to which the patient's taste is accustomed should follow up the initial dose of calomel in about four hours, until from two to four good movements of the bowels have been accomplished.

TREATMENT OF STOMACH.

The stomach is the next organ on which the ravages of the poison seem to exert special virulence. On postmortem, the mucous lining of the stomach is found to be softened and very congested, showing the impossibility of its functioning. It is harmful in severe cases to put either food to be digested or medicines to be absorbed into a stomach whose gastric and mucous follicles, peptic glands, nerve loops and capillary blood vessels are all undergoing changes incident to violent inflammation; hence the necessity of keeping the stomach absolutely empty from three to five days at the beginning of the fever. If an attack comes on after a hearty meal and there are indigestible substances in the stomach, they should be washed out or emptied by a mild emetic, such as hot salt water, or simple hot water until the stomach is distended; then the fauces should be titillated until the stomach is emptied; this aids in producing perspiration and starts the case out with a clean stomach, which is one of the principal organs attacked later on in the disease, and is, consequently, no little advantage.

The best plan to pursue in all cases is absolute starvation from three to five days, just as if the mouth were sewed up, with the exception of drinking water. The best treatment for nausea and vomiting (which is a very persistent symptom) is to use small particles of crushed ice with one-eighth of a grain of cocain occasionally, iced champagne for those accustomed to drink, mustard plasters and ice bag applied over the stomach, provided there is a tendency to hemorrhage. The cocain may be repeated as suppository two or three hours apart until nausea and vomiting are stopped. In some cases tablespoonful doses of milk of magnesia and cream of bismuth with peppermint water in equal parts, assist in allaying the acidity and removing the gases in the stomach. Pressure on the heart from these gases through the diaphragm produces the most disagreeable symptoms, which are sometimes met in treating yellow fever. Bicarbonate of soda is occasionally added to the above prescription when this acidity is continuous. All the resources of the expert are needed to allay an irritable stomach.

TREATMENT OF SUPPRESSION OF URINE.

The way to prevent anuria, from which most subjects die, is to keep the kidneys functioning by water diuresis. What goes in must come out, so water given regularly every hour or two, while the patient is awake and has high fever, is not only very grateful to the patient, but keeps the kidney acting. The water may be charged, alkaline or plain, iced or hot, just to suit the patient, but it must be given with the regularity of medicine to have the desired results. Watermelon seed or orange leaf tea are common remedies among the Creole population of New Orleans. Lithia tablets may be added to the water or mineral springs water of proven diuretic value may be used, but, after all, it is more in the quantity than in the chemistry of the water. This water should be repeated often, but not in large quantities, if nausea be present. High hot water enemas, or a literal warm bath for the kidneys through the rectum, or hot turpentine applications to the spine or abdomen are all recommended by experienced practitioners.

Others have suggested one-grain doses of calomel one hour apart until the kidneys and bowels act, while some have recommended half-pint doses of champagne. Any one who has examined a yellow-fever kidney postmortem with its epithelial and inflammatory degeneration, its blocked, uriniferous tubules filled with débris and toxin products, will know the necessity of washing them out with the vis-a-tergo or abundant water treatment. The condition is a desperate one, hence the multiplicity of remedies and suggestions, all of which frequently have failed.

TREATMENT OF THE HEART.

Yellow fever is a germ or toxin poisoning circulating in the blood, which profoundly depresses the heart's action. The pulse may drop to 50 or 60 beats per minute. After the first two or three days remember the recumbent position is imperative during the existence of this depression. The patient should not exert himself, even to turning in bed. Water and liquid nourishment should be taken out of ideal glass, sick cup, or through a bent tube, so that not even the head is raised in the effort of drinking. The patient should be given 1/60 grain of strychnin hypodermically with caffein to stimulate the heart during this weakened period, when necessary.

As said before, the poison of yellow fever is a powerful toxin circulating in the blood whose main ravages are exerted on the liver, resulting in jaundice, on the stomach, producing pain, nausea and hemorrhage in severe cases; on the kidneys, causing nephritis, hence the albuminuria, uremia; and on the heart, slowing and weakening its action, so that the ratio between the pulse rate and temperature is lost, giving 106 F. temperature with a 70 or 80 pulse beat per minute. Any toxin that is capable of working any or all of these ravages is a powerful factor with which to deal, and any one who views it lightly is either reckless or not experienced in its management.

COMPLICATIONS WITH MALARIA AND DENGUE.

Yellow fever is certainly intimately connected with malaria in many cases, in that it occurs in the patient at the same time and in tropical climates; has the same intermediate host (the mosquito); begins with a chill, head and lumbar pains, so that the first twenty-four hours of the two diseases run in parallel lines in many cases. On this account, whenever the malarial plasmodium is found in the blood examination, 20 grains of quinin has been given with advantage by enema during the first twenty-four hours of the fever. It is not considered safe to give it by the stomach in capsule form, but its action in eliminating the malarial element is just as positive as in uncomplicated malaria. It has been observed by clinicians that nearly every outbreak of yellow fever has been preceded or intermixed with dengue fever. Whether the so-called dengue is another name for mild yellow fever, I will not attempt to discuss here, but will state that the last three epidemics of yellow fever in New Oreans and contiguous territory have been so mild in some patients that many families, thinking it dengue, risked treating themselves, rather than to call in a physician and to undergo the temporary inconvenience of screening and fumigation incident to yellow-fever cases. Many of these mild untreated yellow-fever patients spread the disease and reproduced the severer forms of fever in localities where its origin could not be otherwise traced.

DIET.

During convalescence the liquid nourishment, such as alimentary elixir, milk and lime water, strained soups, barley water, egg albumin, may be administered prudently, but only in tablespoonful doses at the time, and an hour or two apart, until convalescence is well established. All of these articles of diet are to be stopped if disagreeable symptoms supervene.

With Dr. Sternberger's bichlorid of mercury treatment, we have had no personal experience.

This article is intended to deal only with some of the more prominent symptoms and treatment of yellow fever. There are many little details of nursing and nourishing in the convalescent stage that the tact of the nurse and the physician will discover in the progress of the case. What is here recommended is a sort of résumé (consensus) of general methods and treatment usually in vogue by the active practitioners during the last three outbreaks in New Orleans.

POSTOPERATIVE PELVIC EXUDATES.*

W. FRANCIS B. WAKEFIELD, M.D.
SAN FRANCISCO.

Anyone who takes the trouble to investigate this subject carefully will be surprised at the frequency of a postoperative exudate as a sequel to surgical procedures for the relief of the various pathologic conditions which may be found within the female pelvis, due to past or present inflammation.

Let these conditions be what they may—pyosalpinx, hydrosalpinx, or hematosalpinx, ovarian cystomata, hematomata or abscesses, neoplasms of the uterus or periuterine structures associated with degenerative or inflammatory changes—if they produce an exudation which results in the formation of abnormal adhesions, if they bring about hyperplastic changes in the pelvic connective tissue structures, or if they are responsible for an embarrassed pelvic circulation with passive hyperemia, edema or venous varicosity, they may easily lay the foundation for future postoperative exudates.

Although theoretically recognizing the possibility of postoperative pelvic exudates, the question had not assumed practical importance to me until three years ago, when a patient, a few months after having been operated on for bilateral pyosalpinx, returned to me complaining of pelvic discomfort and on examination I was surprised to find a firm, slightly fluctuating mass, the size of an orange, on the left side. Under appropriate general and local treatment the mass entirely disappeared in a few weeks and has not returned since. During the time it was present in the pelvis it produced symptoms almost as severe as the original condition.

Since that time I have made a systematic study of the postoperative local conditions of the patients on whom I have operated for the results of pelvic inflammatory disease. The outcome of this methodical research leads me to the conclusion that postoperative exudates or indurations may be found, to greater or less extent, in about 60 per cent. of the patients on whom we operate for the purpose of relieving the various pathologic conditions produced by severe inflammatory disturbance.

While our patient lies in bed after the operation, and, in fact, up to the time she leaves the hospital, these postoperative tumefactions are rarely observed. It is after the patient begins to lead a more active existence and gradually takes up her general duties, with the increased physical exercise which such duties demand, that these exudates begin to give evidence of their existence. The patient will feel a sense of weight and ill-defined discomfort amounting sometimes almost to pain, on one side or the other, or on both, reflected up around the brim of the pelvis on the affected side, and on examination a more or less pronounced thickening or tumefaction will be found. In general character these tumefactions vary greatly. Sometimes one observes simply an edematous thickening of the broad ligament structures; at other times hard indurations of variable size, from that of an egg to that of a large lemon; again, semi-fluctuating tumors which often are as large as a cocoanut, almost filling the pelvis and pushing the uterus toward the opposite pelvic wall.

In this paper I exclude from the discussion those septic exudates of streptococcic or other pyogenic origin which may occur shortly after an operation and which are accompanied by elevation of temperature, increase in the pulse rhythm, and the other symptoms of a septic state.

In view of the frequency and importance of these non-septic exudates, one would naturally expect a rich literature on the subject. In this expectation, however, one meets with disappointment. Our literature is almost silent on the question. I have been able to find only two or three allusions to the subject in our American literature of recent years.

In the discussion of a paper read before the Chicago Gynecological Society, March 17, 1899, by G. A. Kletzsch on "Remote Postoperative Pelvic Conditions and Their Symptoms, with Report of Cases," Thomas J. Watkins calls attention to postoperative exudates, and attributes the symptoms of one or two of Kletzsch's reported cases to this cause, in which opinion I concur.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The possibility of postoperative exudates is also vaguely suggested by J. Riddle Goffe in a paper read before the American Gynecological Society last year under the title of "The Value of Postoperative Local Treatment in Gynecology," and a direct allusion is made to this subject by George Tucker Harrison in an article entitled, "Conservative Treatment of Affections of the Uterine Adnexa, Its Indications and Limitations," which was read before the Virginia State Medical Society at its thirty-fifth annual meeting. In this article Harrison speaks of "intrapelvic pains due to exudation about the stump."

One wonders whether these exudates have not been generally observed, or whether, having been observed, they were regarded as being relatively unimportant. I regard them as being of extreme importance, and can positively assert, from personal experience, that failure on the part of the gynecologist to recognize early and to treat appropriately these mechanical exudates until they have disappeared, will often result in a state of invalidism quite as pronounced as that which existed prior to operation. This being so, a responsibility rests on us, and I think Goffe's plea for postoperative local treatment in gynecology is well timed.

The pathology of these exudations and indurations seems to me to be simple. I have never subjected any of these patients to any secondary operative procedures, so have, therefore, had no opportunity to make a histologic study of the [illegible] ese pelvic tumefactions. A thoughtful review, however, of the conditions existent in the pelvis after an operation enables one to arrive at a very clear conception of the method of formation of these mechanical entities. Let us suppose we have operated on a patient whose pelvis is the seat of a bilateral pyosalpinx with adhesions. We have performed a bilateral salpingo-oöphorectomy, after having broken up the surrounding adhesions. We have covered up the raw surfaces with peritoneum as best we could, and closed up the abdominal wound. In the pelvis thus operated on there will exist the following local conditions:

1. A break in the arterio-venous circle, caused by the ligation of the ovarian artery and vein, which demands the establishment of a collateral circulation.
2. A deposit of embryologic connective tissue in and around the sites of surgical trauma.
3. An edematous, hyperplastic condition of the pelvic connective tissue as a result of long-continued association with chronically inflamed viscera.
4. Adhesions may tie the pelvic viscera together or to contiguous abdominal viscera.

A careful review of these statements gives us ground for a logical hypothesis concerning the pathology of the postoperative mechanical tumefactions under consideration—the so-called exudates. The first two factors supply the cause; the last two simply intensify the first. It is easy to appreciate how hyperplasia of the pelvic connective tissue, by irritating pressure, and adhesions, by more or less profound immobilization, should both act directly in intensifying an already disturbed venous circulation. Given, then, an inefficient circulation, with the venous stasis, edema, etc., that follows, and the presence of a greater or less quantity of embryonic connective tissue, and we have all the requisites for the production of future pelvic indurations. At about the time that, under ordinary conditions of wound healing, the embryonic tissue would be undergoing absorption, the patient on whom we have operated, who has been in the prone position for about three weeks, the position most favorable to venous outflow, suddenly assumes the upright position and increases her muscular activity, which excites arterial inflow and impedes venous outflow. The venous stasis thus produced is very unfavorable to the absorption of the embryonic connective tissue found in and about the pelvic wound surfaces. So much so is this the case that often not only is the absorption of the embryonic tissue hindered by this local irritation, but an actual increase of new tissue is produced. It is my opinion that it is the accumulation of an excessive amount of embryonic connective tissue substance that forms our postoperative pelvic tumefactions and constitutes our so-called pelvic exudates. If this embryonic tissue is rich in fibers our tumefactions appear as firm indurations; if, on the other hand, there is a scarcity of fibrous elements and an abundance of soft, young cells, we then get our less resistant, semi-fluctuating masses. As the pelvic circulation improves and gradual absorption of this embryonic tissue takes place, our tumor disappears. If, on the other hand, no improvement in the circulatory condition is brought about, and no effort is made to encourage the absorption of this new tissue, it becomes a more or less permanent structure in the pelvis, and, in time, will gradually change from the embryonic type to the adult connective tissue type, until, eventually, as has been demonstrated to me more than once, a hard, fibrous mass, formed, at least in part, of adult fibrous tissue, will occupy the site of the original pelvic induration, and may, perchance, give rise to a complex symptomatology quite as distressing, if not as serious, as the original condition for which we operated.

Careful observation leads me to believe that these products of a disturbed circulation can often be prevented by a prolonged convalescence, the assumption of activity very gradually, aided, when possible, with general hygienic and local depleting measures. The general prophylactic measures to be adopted are, of course, those which tend to improve the general circulation, such as light massage, alcohol and salt friction rubs, tepid sponge baths, etc. Local depletion, at this stage, consists in copious hot douches once or twice daily.

Such postoperative care as just outlined is, of course, impracticable in our hospital service, and can only be applied to a small percentage of our private patients, but it is a wise practice when it is carried out, and when it can not be carried out we must follow our patients up and give each one whatever postoperative treatment, both local and general, the exigencies of her case demand and her circumstances and environment render possible.

When, some time after operation, examination reveals the presence of a pelvic induration or tumefaction, we must at once institute appropriate treatment and continue this treatment until the so-called exudate undergoes absorption. Physical exercise must be kept within very reasonable bounds, and all the excretory organs kept active, especially the skin. Local treatment will consist in stimulating and depleting measures. The two most useful are the copious hot douche and the depleting tampon. The douche may be used once, twice, or three times daily, depending on the urgency of the case, and should always be taken in the recumbent position, preferably with the hips elevated. The amount of water to be used in the douche should not be less than two gallons, and the temperature should be as high as the patient will permit—from 110 F. to 120

F. The tampon must consist of some light, fluffy and non-absorbable material—something that will not ball up into a hard, irritating mass. Fine Australian lamb's wool makes the ideal material for tampons. The depleting medicament to be used on the tampon will differ with individual preference. The menstruum must be one which encourages free exosmosis, to which may be added astringents, antiphlogistics, or antiseptics. The local application of electricity might, in some cases, be beneficial. Local pelvic massage, as suggested by Brandt, is very serviceable in the hands of some men and very harmful in the hands of others. The difference is purely a matter of individual proficiency in its use.

Incision and drainage of these pelvic masses through the vault of the vagina naturally suggests itself. I have never found it necessary so far, although, in one case, I was tempted to do it. I was glad afterward that I refrained from surgical interference, as continuance of depleting local treatments soon brought about complete resolution of the exceptionally large, semi-fluctuating tumor present in this particular case.

In conclusion, I simply wish to say that I am thoroughly convinced that, as we study more intelligently and carefully the local postoperative conditions existing in patients whose pelves have been the seat of acute or chronic inflammatory disease, the more necessity we will find for intelligent postoperative treatment, and the more gratifying will be our remote operative results to both the patient and ourselves.

DISCUSSION.

Dr. H. O. Pantzer, Indianapolis, challenged the paper for being at variance with the ordinary principles of pathology. The term used—pelvic exudates—implies an infection giving rise to pyosalpinx. This disease, he said, is practically always accompanied by temperature. These cases can be ascribed more properly to postoperative hemorrhage. All the phenomena present can be explained on such hypothesis. Dr. Pantzer believes that had Dr. Wakefield done a posterior colpotomy he would have found, in addition to pus, the evidences of blood. These cases may become suppurative and develop temperature at any time after operation, even without infection. They are to be grouped under the head of incomplete hemostasis or postoperative hemorrhage.

Dr. C. O. Thienhaus, Milwaukee, Wis., said that there are two reasons why we do no longer hear so much of postoperative exudates. The first reason is that surgeons have given up the use of silk ligatures within the abdomen. Five years ago Dr. Thienhaus called attention to the fact that when silk is used within the abdomen and the operative field is infected during the operation or becomes infected after operation, the silk ligatures also become infected and often form a nucleus for later exudates, from which fecal and other fistulas and other conditions may originate, the correction of which proves a troublesome and dangerous task even to the expert surgeon. The other reason is that surgeons now do more complete operations. If, during an operation for pus tubes, a part of the tube is not excised and thereby a small area of infection is left, postoperative exudates may form.

Dr. D. H. Craig, Boston, reported a case which interested him greatly. About eighteen months before coming under his observation, at the Free Hospital, a woman had both tubes and ovaries removed. She did not make a satisfactory recovery. Dr. Craig found a mass about the size of a lemon in the region of the broad ligament; it was easily palpable through the vagina. The patient also had an adherent retroversion and badly irritated, lacerated cervix. The cervix was repaired, and the mass was still palpable in the broad ligament. The abdomen was then opened and the adherent uterus loosened and suspended. The most diligent search failed to reveal any tumor in the broad ligament. The patient was discharged from the hospital at the end of four weeks. Two weeks afterward she reported at Dr. Craig's clinic with the mass as plainly palpable as ever. He called in several other men, and they all felt the tumor. She returned a week later, and not one of five men could find the mass. At the end of another week she reported again with the mass as manifest as at her first visit. The question is, what was the mass? Dr. Craig believes that it was a broad ligament varix, and that the lithotomy position maintained during the first operation, superseded by the Trendelenburg posture had drained the varix so that it disappeared. If this was a postoperative exudate, Dr. Craig would like to know what to do.

Dr. J. Riddle Goffe, New York, stated that his attention has been directed to this line of treatment in his work for the relief of sterility. In these cases a very slight cobweb adhesion may be the cause of the most persistent sterility. In operating in cases in which he did not find it necessary to remove any tissue, and contented himself with breaking up adhesions and setting the organs free to perform their functions, it occurred to him that it might be wise to promptly begin postoperative treatment, and by doing so he has been able to attain some excellent results. He referred to the depleting effect of tampon treatment and hot-water douches, and advised against waiting until the exudate can be felt before beginning that treatment. If the douches and tampon are used too early, however, the normal healing process is prevented; therefore, he waits until the twelfth day, or even the fifteenth, before instituting this treatment. The etiology of these postoperative adhesions is more or less obscure. In most cases there is infection, although not of a virulent character, and Nature as a matter of protection throws out a certain amount of plastic exudate. This, as a rule, does not develop into an abscess. Postoperative treatment will assist materially, not only in preventing the exudation from forming, but also in hastening its absorption after it has occurred. It is important to follow up patients and to examine them carefully after operative procedures in the pelvis. In the last few years it has become a growing ambition to get patients up too early. Recently, before the New York Obstetric Society, a physician said that he allowed his laparotomy patients to get up as soon as they wanted to, some being on their feet the day following the operation. This is going to an unfortunate extreme. In order to get the best results, it is necessary to keep patients quiet longer, and when there has been extensive inflammatory exudate preceding operation, one may expect more or less recurrence of it after operation. Hence it is well to give postoperative treatment before discharging the patient.

Dr. C. S. Bacon, Chicago, thinks that there are several causes for this condition. It is sometimes due to hemorrhage; sometimes to sepsis; sometimes, possibly, to varix, and it may be the result of a non-virulent infection. Even a gonorrheal infection, at a late stage, does not necessarily produce much temperature, and thus it might be overlooked entirely. Infection from the intestinal tract might account for some of these cases. Dr. Bacon feels quite certain that some of these exudates are of infectious origin. The same condition of affairs is seen in a mild breast infection, with a beginning abscess, but it almost always disappears if treated properly by absolute rest, with support of the breast and the application of cold or heat. This is the reason for the good effects of the treatment in the cases reported, and it also emphasizes the point made by Dr. Goffe that there is great danger in getting patients up too early after operations, and in not getting them up in the proper way. The postoperative treatment should be like the management of the puerperium. It is not necessary to have the patient in bed for a week or two and then have her get up for a whole day. When she begins to get up, let her do so carefully and gradually. When the postoperative management of a case is carried out like the management of the puerperium, fewer of these conditions will occur.

Dr. J. H. Carstens, Detroit, thinks the percentage of these cases depends on the surgeon. If he is a broad, all-around man, he will have only about 4 or 5 per cent. The trouble is that surgeons are all specialists; they are not broad enough to see everything. Some surgeons have too poor a technic.

They make mistakes, too. Dr. Carstens has seen men tie off a tube containing pus, and the patient has a postoperative exudate. The way to do is to cut the tube in a V-shaped way and then bring the ends of the V together and cover it all over with peritoneum. Then, as a rule, there will not be any adhesions. To dig through the intestines and try to break up adhesions is bad. If it is in a pus case, Dr. Carstens advised taking a little rubber tube with a cross piece, putting it in the cul-de-sac and draining through the vagina. In the place of peritoneum one can use Cargile membrane. Dr. Carstens has most trouble in cases in which he does conservative operations; those in which he leaves half a tube or an ovary, or in which he does an abdominal or vaginal hysterectomy and leaves one ovary. Another thing at fault is the after-treatment of these patients. They do not get enough to drink. One can not get absorption and elimination from solid tissues. These patients need liquids, and must be flushed out. The eliminating organs must be opened up. Every patient should receive two or three quarts of saline solution by rectum or under the breast immediately after the operation. They must have plenty of water, at least three quarts a day, one-half pint or a pint at a time, if the stomach is all right. Then, if there is a little exudate, Dr. Carstens uses a mercurial. He commences with protoiodid of mercury, one-eighth of a grain every three hours, until he has given about thirty doses. That acts as an alterative and absorbent and opens up the lymph channels, and the patients get along better. They have comparatively few complications.

Dr. **Frank T. Andrews**, Chicago, agreed with Dr. Carstens that infection often comes from the cut extremity of the tube, but his method of prevention has been more radical than Dr. Carstens'. He removes the whole tube, even into the horn of the uterus, and then closes the wound with a web stitch, often not ligating the uterine and ovarian arteries, simply running a stitch along the top of the broad ligaments. That, however, depends entirely on the individual case.

Dr. **H. C. Crowell**, Kansas City, said that the worst sequelæ and the most important are those that follow these operations. If it were not for the kindness of Nature in absorbing adhesions, surgeons could not enter the abdominal cavity. However careful the procedure, the endometrium is more or less disturbed and sequelæ result. Dr. Crowell believes that the age of the silk suture has passed, but stated that catgut is a source of trouble if not carefully prepared. The knot in the suture gives rise to an exudate which may end in an abscess. He believes that a shorter-lived catgut may be used safely, because the ligation of vessels requires a very short time for perfect occlusion. The technic is the most important point. Dr. Crowell thinks that patients ought to get up early, as fluids gravitate toward the pelvis if the patient is in the erect position. He advised getting the patient up on the second or third day and encouraging circulation by putting her on her feet and allowing her to walk. Exudates are then absorbed. He has allowed hysterectomy patients to get up on the second day and always inside of a week. He is satisfied that these patients do better than they would if kept in the recumbent position for a long time.

Dr. **W. F. Wakefield** said that the class of cases Dr. Pantzer spoke about are ruled out of the discussion. The paper expressly excludes them. These are mechanical conditions that are practically never found while the patient is in bed, and Dr. Wakefield has examined these patients carefully for the last two or three years. It is after the patients get up that these conditions are found, and even then they depend on how slow convalescence has been. If very slow, exudates are rarely found at all; if rapid, in from two to eight weeks after the patient begins to walk, one finds these tumefactions. Dr. Craig's case illustrates exactly the class of cases referred to. Dr. Wakefield said that he could have mentioned from fifteen to twenty similar cases. Gynecologists have not been looking for these indurations and, therefore, they have not found them as often as they have been present. These tumors are pure mechanical entities. Just what the mechanism is he is not prepared to say. Sepsis has nothing to do with it. He has never found sepsis in any case. An embarrassed circulation is probably the largest factor, and this circulatory irritation acting on the new tissue accounts for the condition in all likelihood. He has never cut into one of these tumors, and he believes that if he had he would not have found anything. Nevertheless, unless the absorption of this mechanical mass is brought about, the patients will suffer from ill-defined pelvic irritation, almost as troublesome as the original condition for which they were operated on. Dr. Wakefield explained that he used the term exudate because it is the term used in the literature. It refers to any tumefaction about the field of operation. He thinks it is a misnomer. Throughout his paper he speaks chiefly of the *so-called* exudates and calls them mechanical tumefactions. He does not believe that they are real exudates. The percentage of their occurrence depends not so much on the technic of the operator as on other things. He removes tubes just as Dr. Carstens does. When he mentioned 60 per cent. he did not mean that there was a definite tumor in that percentage of cases, but that on examining these women in from six to eight weeks after operation he has found in 60 per cent. either a thickening of the broad ligament or a distinct tumefaction. He does not believe in letting patients get up early. In carrying on a series of experiments on patients he found that these tumefactions are almost invariably produced in patients who get up early. The longer the patient can be kept in bed and the more protracted the convalescence the less likelihood there is for the formation of these tumefactions.

HERNIA OF THE TUBE WITHOUT THE OVARY.*

FRANK T. ANDREWS, M.D.
CHICAGO.

I wish to report four cases of hernia of the tube without the ovary, one furnished by Dr. James H. Haberlin, Pawtucket, R. I., and another by Dr. H. H. Judd, Chicago, the third and fourth being from my own practice.

I have made an exhaustive search for recorded cases of hernia of the female pelvic organs and find 362 cases sufficiently well reported to be of value. These cases, with my own, may be tabulated thus:

	Cases.
Hernia of tube without ovary	46
Hernia of ovary and tube	80
Hernia of ovary without tube (or tube not mentioned)	167
Hernia of non-gravid uterus	43
Hernia of pregnant uterus	30
Total	366

Early in the second century, Soranus of Ephesus described the first case of hernia of the ovary. No further observation was made until 1716, when Louis Leger de Gouey of Rouen wrote an article citing a case of intrahernial tubal pregnancy.

The literature of tubal hernia is practically the same as that of ovarian hernia, but in 1893 Lejars[1] published an article on hernia of the Fallopian tube without the ovary; and in 1901 Dr. Paul F. Morf[2] published a very complete work on the same subject, reporting 24 cases, including his own.

REPORTS OF FOUR CASES.

I wish to record here the following cases:

Case 1 (Reported to me by Dr. H. H. Judd).—Patient, a Swedish widow, 56 years of age, and admitted to Cook County Hospital May 12, 1905. First noticed small tumor in left groin fourteen years ago after doing some heavy lifting while eight months pregnant. Tumor was easily reduced, and gave no trouble until one and one-half years ago, when it again appeared and reduction was impossible. Physician was called who obtained reduction. This attack was accompanied by considerable pain at site of tumor, restlessness, irritability and vomiting. Had similar attacks one year ago, also three months ago. Present attack is accompanied by more pain than before, and patient had vomited several times on day of admittance.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Revue de Chirurgie, January and February, 1893.

[2] Annals of Surgery, 1901.

Examination showed small irreducible tumor in left inguinal region, firm in consistency, except at distal extremity, where it was tympanitic. Tumor gave slight impulse on hard coughing and was somewhat tender.

Operation performed by Dr. Kahlke. Incision over tumor, sac opened, and dissected loose. Sac contained portion of ileum, which was very dark colored, a portion of broad ligament and a loop of Fallopian tube while ovary was situated within abdominal cavity, but firmly pressed against femoral ring and neck of sac. Tube and ovary replaced, sac excised and wound closed with catgut. Chart of temperature, etc., was as follows:

	Pulse.	Temp.	Resp.
On admittance	100	98	30
After operation	108	101	30
Third day	84	98.8	24

Patient made uneventful recovery and was discharged June 13, 1905.

Case 2 (Reported to me by Dr. J. H. Haberlin).—Mrs. B. N., 45, white, United States.

Family History.—Father died at 58 years of pulmonary tuberculosis after four years' illness. Brother, third born, died at 23 of pulmonary tuberculosis, two years' illness. Brother, second born, died at 35 years of Landry's paralysis. Brother, fifth born, died at 39 years of chronic nephritis and hepatitis (alcoholic etiology). Mother living and well at 76 years, excepting slight edema of legs and periodic subacute rheumatic attacks. Yields readily to treatment. Brother, 50 years, in good health. No one beside the patient ever had a hernia.

Previous History.—Patient was a full term child, born in normal labor. Never sick in infancy. Breast fed until late in infancy. Had measles and pneumonia in early childhood. Otherwise well. Jumped from a high wall at 7 years of age and received hernia in the left groin. Twelve years ago, while lifting heavy weight, received hernia in right groin. Was treated by Dr. O. Edwards, Boston. He injected a solution that caused intense inflammation, with consequent great suffering. After a week, the symptoms of inflammation subsided and patient was discharged cured. The left hernia never recurred, but the patient thought she felt the right hernia recurring and dropping lower down. The doctor, when again consulted, however, insisted that the hernia was cured and refused further procedures. Every since this time, patient has had a hernia in the right groin.

Personal History.—Patient uses alcohol moderately. Has worked in a department store as clerk since husband's death (fifteen years ago) until about two years ago. Appetite good. Bowels slightly constipated Sleeps well. Disposition cheerful. Menses appeared at 16 years; were then regular, flowed six to seven days without pain until 19 years of age. Then patient suffered pain during the flow. Married at 20 years. Had child at 21 years and at 25 years. Labor normal. Never miscarried. Has had leucorrhea ever since marriage almost constantly, but amount and character has varied. Sometimes discharge was thick, white and tenacious, sometimes it was thin and white or yellow. Widow for fifteen years.

Present Illness.—I was called to see the patient May 14, 1905, at 8:30 p. m. Found her seated in a rocking chair, tearful and evidently suffering great pain. (Patient usually a stoic.) Hernia has been down four days and patient is unable to reduce it. Usually she can reduce it at its worst stage by lying on the floor and putting feet on the bed and then gently maniplating the tumor. Patient has not menstruated for six weeks. Never before has this latter occurred except in pregnancy.

Examination.—Firm rounded tumor as large as grape fruit. Patient placed in dorsal decubitus with feet raised, and I manipulated the hernia to obtain reduction. Manipulation caused great pain if done at all but gently. Tumor gradually reduced to size of small lemon, when further reduction was absolutely impossible.

Diagnosis.—Ruled out tuberculous femoral glands, hernia of tube and ovary and enterocele in favor of incarcerated epiplocele (inguinal).

Operation.—This was advised as only resort. Patient consented. Patient was removed to St. Joseph's Hospital, Providence, R. I. Dr. William L. Harris of the surgical staff agreed that it was epiplocele, but thought it femoral and strangulated. In discussion, he did not insist on the latter condition, however. Operation was by Dr. Harris. Incision parallel to Poupart's ligament. Sac exposed and seen to contain a light yellow-colored serum. Tumor as large as small lemon, as before mentioned. Tumor punctured and serum allowed to escape. Sac (peritoneal) incised and the cyst wall seen to be connected to one of the fimbriæ of the tube, all of which were in the wound. Fimbriated end of the tube amputated. Hernia was femoral.

Postoperative History.—Ideal patient; ideal result. Left the hospital fifteen days after operation. Was obliged to use napkins every day in the hospital for slight saneous discharge. Pain in wound week after operation disappeared in three days. Menses appeared two weeks after return home; lasted scarcely five days, with decidedly less pain and discomfort than usual.

Case 3 (author's).—March 24, 1904, I operated for Dr. Childs of Roseland, Ill., on Mrs. K. (multipara, aged 32, married eleven years), for diseased appendages. There was a history of gonorrheal infection three years previous, followed by salpingitis. A right inguinal hernia, caused by carrying pails of water, had existed for sixteen years. Operation disclosed the usual condition of adhesion on both sides, except that the right tube led in a straight line to the hernia. About one-half the tube was adherent, together with omentum in the hernial sac. The internal inguinal ring was patulous, a loop of bowel evidently slipping in and out of the sac readily. I removed the appendages and repaired the hernia. The patient made a normal recovery.

Case 4 (author's).—Mrs. W., aged 23; admitted to Mercy Hospital April 30, 1905. Married one and one-half years. Had a child born March 2, 1905.

Previous History.—No tuberculosis in family. Had as diseases of childhood measles, whooping cough and scarlet fever. Suffered occasionally from pain in abdomen and diarrhea. Periods began at age 13, and were regular every four weeks. Flow profuse and not very painful. Never had any weakness or pain in the right groin nor knew of any tumor or hernia. After birth of a child, March 2, 1905, she evidently suffered from infection, giving a history of irregular chills, alternating with high fever. At first there was considerable vomiting. Since then there has been great pain and tenderness in the right inguinal region, with the gradual development of great swelling.

Examination.—Temperature 101 to 103; pulse 100 to 140. The abdominal wall on the right side was swollen and edematous, the swelling extending upward to the ribs and downward on to the anterior surface of the thigh. Digital examination revealed a mass involving the right appendages, but nearly filling the pelvis. The outlines of ovary, tube or uterus could not be distinguished.

Diagnosis.—Pelvic abscess due to rupture of right pyosalpinx with adhesions to anterior abdominal wall.

Operation.—I was assisted in the operation by Drs. Barnes and Norris. Ether was given by Dr. Mitchell. Usual preparation. Trendelenburg position. Incision 4 inches long in median line. Pelvic organs on right side were matted together and covered by adherent omentum and intestine. After separating the omentum and bowel from the mass, the uterus could be seen drawn to the right. Laparotomy sponges were inserted to wall of the field of operation. On separating some uterine adhesions with the finger and drawing the uterus to the left, it was discovered that the right tube and round ligament had been severed at the uterine horn. On introducing a retractor to lift the abdominal wall, pus could be seen escaping from the internal inguinal ring into the peritoneal cavity. The parts were cleansed of pus, and the finger inserted through the ring into the cavity of the abscess. An incision was made through the skin into the hernial abscess and a gauze drain inserted. A gauze drain was also used in the median incision and the remainder of the wound closed by silk-worm gut, interrupted sutures. The patient made an uninterrupted recovery and left the hospital May 30.

The following cases I have gleaned from the world's literature:

Aubry :[3]Age 70, postmortem examination revealed hernia of the Fallopian tube. Tube had passed through femoral ring and lay in front of the pectineus muscle, between the adductors and the femoral vessels.

Berard :[4] Age 45, acquired crural hernia of the right tube; irreducible. Exploratory puncture evacuated clear fluid; patient showed symptoms of a phlegmon and death occurred seven days after evacuation. At autopsy, a seropurulent peritonitis was found. The neck of the sac passed through the crural ring, and within it the Fallopian tube, somewhat enlarged. No other viscera were found in hernial sac.

Boudin :[5] Age 50, acquired crural hernia: irreducible. Operation, sac was found to contain the Fallopian tube alone, strangulated by neck of sac. Recovery.

Brunner: Case 1.—Age 68, irreducible; acquired crural hernia. Operation; the sac being opened, clear fluid escaped, disclosing swollen and edematous extremity of right Fallopian tube; the tube was reduced; a lipoma situated in upper portion of sac was isolated and extirpated. Recovery.

Case 2[6].—Age 38, acquired inguinal hernia; irreducible. Operation; clear fluid tinged with red escaped from sac after incision. *Right Fallopian tube* was contained in sac. By making traction on tube, the ovary was dragged forward, but was found to be perfectly healthy. Tube was reduced and the sac ligated and resected. Recovery.

Chiene :[7] While dissecting the body of a woman, aged 73, found an obturator hernia; the sac contained two-thirds of the Fallopian tube and two inches of the ileum. The bowel was gangrenous and had given away. On the opposite side were two obturator herniæ, an anterior sac formed of parietal peritoneum and the posterior sac containing the outer half of the Fallopian tube. A year previous she had been successfully operated on for strangulated femoral hernia.

Demoulin :[8] Operated in a case of hernia of the tube, where there was adherence to the sac; traction brought the ovary to view.

Deaver, J. B. :[9] Strangulation of the fimbriated extremity of a Fallopian tube of the right side, which was thought to be a femoral hernia.

Dolbeau :[10] Tumor in inguinal region presenting signs of an abscess of inguinal canal. *Incision* pus escaped. Peritonitis and death. Autopsy showed pus collection surrounded by hernia sac, which contained likewise a serous cyst. *Incision* of cyst revealed Fallopian tube.

Dupont :[11] Age 38, in fifth month of pregnancy, acquired inguinal hernia. Exploratory puncture caused escape of yellowish fluid. Operation revealed herniated Fallopian tube, organ was reduced. Recovery.

Erichsen :[12] Age 37, acquired left strangulated hernia. Operation sac contained clear fluid and the *swollen* fimbriated extremity of the Fallopian tube which was tightly nipped at the neck of the sac. Tube was returned into abdomen. Recovery.

Ferd :[13] Child, age 3 weeks; at autopsy a hernial sac containing exclusively the fimbriated extremity of the Fallopian *tube was discovered* external to the round ligament. It was easily reduced, but returned immediately after pressure was removed.

DeFrancisco :[14] Age 32, acquired inguinal hernia of the left tube, irreducible. Operation; sac exposed and opened. Contained adherent tube; the latter was separated as much as possible; sac was separated from surrounding parts and closed with sutures and stumps replaced. Recovery.

Frank :[15] Age 21, left tubal hernia, acquired. Operation; removal of tube and sac; *recovery*. Had been operated on when *a child* for hernia on *same side*. No trace of ovary could be found in last operation.

Goepel :[16] Age 62, acquired right crural hernia, irreducible. Celiotomy; sac contained serous *fluid* and dilated Fallopian tube; it was removed, as was likewise the corresponding ovary, which was sclerotic. Recovery.

de Gouey[17] (of Rouen, in 1706): Young woman, hernial sac of right groin; when sac was opened, *clear fluid escaped*. (On reading original, this is seen to be evidently hernia of tube.) Inside another bag a live fetus, 6 inches long, was found; latter was removed, tying the cord. Placenta likewise came away; it was fastened to circumference of musculus obliquus externus.

Lejars :[18] Age 39, acquired inguinal hernia of the right tube; strangulation. Operation; sac contained blood-stained fluid and Fallopian tube; tube was excised with sac; it was gangrenous in places. A portion of the wall of the urinary bladder also became herniated through the internal ring in company with the hernial sac. Recovery.

Lentz :[19] Age 52, acquired crural hernia of the left Fallopian tube; dropsy of the hernial sac. On dissection, bloody fluid was evacuated. The Fallopian tube was ligated and excised with the sac. Recovery.

Jalaguier :[20] Age 19 months; since the age of 6 months right inguinal hernia. Operation; sac, formed by the canal of Nuck contained a knuckle of the right Fallopian tube. Excision, followed by recovery.

Kousmine :[21] Age 36; left acquired inguinal hernia; irreducible. Operation; after opening sac, large quantity of seropurulent fluid escaped. This disclosed a cystic Fallopian tube, the external half of the tube only occupying the sac. Recovery.

Maydl :[22] Age 47; acquired femoral hernia; irreducible. Operation; after incision, escape of hemorrhagic fluid, which disclosed knuckle of Fallopian tube in the femoral canal; the uterine half of the tube was converted into a cyst; the strangulated portion of the tube consisted of a loop, which had passed back into the abdominal cavity after having passed out through crural ring. He extirpated the sac containing the tube; also removed the corresponding ovary. Recovery.

Moller :[23] Age 46; right inguinal hernia, acquired. Herniotomy; sac was found to contain a pyosalpinx. On account of collapse operation was hastily ended. Recovery with a formation of a fistula.

Morf :[24] Age 24; left congenital inguinal hernia of the Fallopian tube; irreducible. Operation; sac was removed with its contents, together with left ovary; sac contained omentum, into which mass the tube was traced, its fimbriated extremity being completely surrounded by omental tissue; from it the infundibulo-pelvic ligament could be traced; passing out of sac. Recovery.

Morton and Butler: Case 1.—Age 46; acquired right inguinal hernia; irreducible. Operation; sac was found to contain right Fallopian tube and its fimbriated extremity. Reduced sac ligatured and cut away. Recovery.

Case 2.[25]—Age not known; strangulated right femoral hernia. Herniotomy; sac contained gangrenous omentum and gangrenous ruptured bowel and end of right Fallopian tube, which was gangrenous to the extent of half an inch. The patient died from shock twelve hours later. Autopsy.

Nelaton :[26] Child died twenty-four hours after birth; right inguinal hernia containing Fallopian tube.

Picque and Poirier :[27] Age 78; acquired obturator hernia; strangulation; death. Autopsy, sac formed by peritoneum contained a knuckle of intestine, an epiplocele and left tube with a part of its ligament.

Pollard (Bilton) :[28] Age 37; acquired strangulated femoral hernia. Operation; sac contained clear fluid and the swollen fimbriated extremity of the left Fallopian tube, which was tightly nipped at the neck of the sac. The constriction was divided and the tube returned into the abdomen. Recovery.

Salnelle :[29] Age 19 days; congenital hernia on the right side; strangulated. Operation. Sac was opened and was found to contain the right Fallopian tube, red and swollen. Death.

Scholler :[30]Age 20 days; congenital inguinal hernia; convulsions and death. Autopsy showed hernia of the right tube. It was red and swollen; the round ligament was a little shorter than that on the other side and the uterus slightly displaced.

de Vaucher :[31] Age 23; probably congenital inguinal hernia; irreducible. Operation; sac contained left Fallopian tube without ovary; sac and tube excised. Recovery.

Vogel :[32] Age 38; acquired inguinal hernia; irreducible. Operation; opening of the sac; escape of blood-stained fluid, disclosing right Fallopian tube in bottom of sac. The tube was returned into abdominal cavity; the sac removed. Recovery.

Voigt :[33] Age 36; acquired right inguinal hernia; irreducible. Swelling "opened," discharged a serous fetid pus, after which patient's general condition improved. The next day a small black, gangrenous body was found in the dressings, which was recognized as the Fallopian tube. Recovery.

Thomas :[34] Age 36; acquired hernia on the right side; irreducible. Omental hernia on the left side, reducible. Operation. Right crural hernial sac contained the fimbriated extremity of the Fallopian tube. Gimbernat's ligament (crural hernia) was nicked and the hernia reduced. Recovery.

Trinci :[35] Age 47; X-para; crural hernia; irreducible; appeared after last pregnancy; symptoms of strangulation. Operation; sac contained the right tube; resection of the tube above the strangulated point; radical cure. Recovery.

Vassal :[36] Reports another observation by Broca. Child, age 14 months; congenital inguinal hernia; strangulated *for* twenty-four hours. Herniotomy, the tube was *found in the* sac. Temperature after operation 37.4 C.; the following days, 37. Recovery.

Waldeyer :[37] Demonstrated before the Obstetric and Gynecologic Society of Berlin, June, 1896, an inguinal hernia, in which lay a tube.

Walter[38] Aged 14 months; at 6 weeks of age tumor was first observed in inguinal region. Operation; the hernia contained a loop of small intestine and the Fallopian tube strangulated moderately. Reduction. Recovery.

Walther (G. Th.):[69] Age —; right inguinal hernia. Operation; sac was found to contain a cystic dilated accessory. Fallopian tube (congenital malformation).

Walther (G. Th.):[39] Age —; right inguinal hernia. Operation; displaced to the right. The right tube and corresponding tubo-ovarian ligament extended into right inguinal ring. On left side, internal inguinal ring was occluded by fimbriated extremity of the left tube passing into it.

Case 2.[41] Age 6 months; congenital inguinal hernia of the left tube found; postmortem the sac contained the tube only. The left ovary was situated in the internal iliac fossa on the right side; tube and ovary occupied their normal position. Uterus was displaced to the left.

Wyeth:[42] Age 38; strangulated right inguinal hernia; when sac was opened congested Fallopian tube was found; pus and feces welled up from the abdominal cavity through the neck of the small loop of intestine was found gangrenous, ruptured; death six hours after operation.

As hernia of the Fallopian tube, without the ovary, constitutes less than 10 per cent. of the recorded cases of hernia of the pelvic organs, it is evident that a description of the anatomy and the etiology may be best considered in a future paper dealing with the greater subject. Pathologic conditions within the tube may also be better discussed then.

The diagnosis, before the opening of the sac, has not been made, but, perhaps, in the case of a small painless hernia the tilting of the uterus toward the hernia might be sufficient evidence that the sac held only the tube.

DISCUSSION.

Dr. T. B. Eastman, Indianapolis, said that a woman was referred to him with what had been diagnosed as a labial abscess on the right side. It had been incised several times, but the discharge continued. Dr. Eastman made a free incision and after a rather difficult dissection he came on a badly inflamed appendix which was open at the end and discharging pus. Of course this was responsible for the patient's condition. Dr. Eastman removed the appendix and the patient made a good recovery.

Dr. A. Goldspohn, Chicago, stated that a number of years ago a woman of at least 60 years of age came under his care as a hospital patient. She had always been fairly healthy, and she had a femoral hernia of small dimensions that had not given her much trouble. It became irreducible, however, and occasioned more or less pain, and she had had something of a convulsion, as her illiterate relatives described it. Examination showed a small tumor in the region of the left femoral ring, corresponding to a femoral hernia, that was not reducible by ordinary taxis. On opening the sac the ovary became apparent; it was adherent, with a small amount of omentum. The operation presented no difficulty and the patient made a good recovery.

SOME COMPLICATIONS OF PREGNANCY. TREATED SURGICALLY.*

FRANCIS D. DONOGHUE, M.D.
BOSTON.

Within comparatively few years, our knowledge of appendicitis and neoplasms, complicating pregnancy, has been considerably increased.

As a rule, the surgeon has been called to treat these conditions, and therefore they have been studied more from the standpoint of the influence of such operations on pregnancy than of pregnancy on conditions which otherwise might be considered operative.

In this country continuous observation of a woman during pregnancy is almost unknown.

The number of complicated cases, therefore, which have been observed by any one individual has been limited. It is true that in some well-to-do families observation is practiced; but as the importance of this observation is recognized, the occasions for it decrease.

Most obstetrical cases are in charge of general practitioners, and this condition will, undoubtedly, continue. The combination of a skilled obstetrician and surgeon is not a common one, and while the obstetrician may be most skillful in all that pertains to diagnosis of position and in the performance of obstetrical operations, the men in charge of these cases still turn to the surgeon when other operative complications are present.

Surgical interference has also been encouraged by the attitude of obstetricians toward "operative delivery" in cases which may be called, from the surgical standpoint, uncomplicated. This is on the increase, especially in large cities,[1] and, undoubtedly, tends to encourage surgical intervention in a growing list of obstetrical conditions. The practitioner, who has seen the development of "surgical trusts" under the name of "hospitals," hesitates when he considers what his financial end is to be if he further countenances the fallacious idea that patients can not be successfully treated at home.

On the other hand, the desire for personal consideration and to remain at home, if possible, is still strong among those who have not contracted "the hospital habit."

With the large number of competent operators who desire only fair remuneration for services rendered it rests with the general practitioner whether or not he will lose the best part of his practice among the great middle class as he has lost it among what may be considered the opulent poor and the economically inclined opulent.

The care of the pregnant woman is by far our most important duty, and any improvement in treatment or in the care which tends to lessen her dangers during this trying period is of utmost importance.

The value of recognizing deviations from the normal early in the conduct of these cases can not be overestimated; acting with conservative promptness in the presence of dangerous complications will save many lives, both fetal and maternal.

Surgical interference is more important in certain conditions in the pregnant than in the non-pregnant.

It has long been an accepted fact that high maternal temperatures are dangerous to intrauterine life, and that when the temperature runs over 104 F. for a continued period of time, no matter from what cause, it is invariably fatal to the child *in utero*.[2]

Suppurative conditions with much lower temperature are dangerous, especially if the process is active in close relation to the uterus.

The study by Straviskiadis of twenty-four cases, including pneumonia, typhoid fever, pyemia, etc., in which macroscopic, microscopic and bacteriologic examinations were made, is a distinct addition to our knowledge of this subject. His conclusions are: 1. An acute endometritis which is often hemorrhagic is of frequent occurrence in acute, infectious disease. 2. This inflammation is caused by the specific bacteria that caused the disease or a complication. 3. Particularly favorable conditions are present during pregnancy and the puerperium for the increase of the bacteria which reach the uterus through the blood current. 4. Abortion or premature labor is frequently due to endometritis of hematogenous origin.[3]

The intimate relation existing between the appendicular lymphatics and those of the broad ligament is of importance in determining the influence of septic conditions of the appendix on pregnancy;[4] but the hematogenous channel, in view of the fact that there is increasing evidence that septic emboli may cause disturbances in the gastrointestinal mucous membrane and elsewhere seems the most probable route of endometrial infection.[5]

APPENDICITIS.

Appendicitis frequently complicates pregnancy. The condition of obstinate and continued constipation which is so frequent during pregnancy must be looked on as a predisposing cause. Add to this increasing deviation from the usual physiologic condition of the pelvic organs of women between the ages of 15 and 45, the mechanical disturbances and congestion resulting from the rapidly growing uterus, and the wonder increases that troubles are not more common. In many cases an absolute diagnosis has not been made, because of the mildness of the symptoms.

In the diagnosis of appendicitis during pregnancy the usual signs may be obscured. Vomiting is often concurrent with pregnancy. As a rule, the pain is localized at the diaphragmatic attachments, while acceleration of the pulse and elevation of the temperature are exceptional.[6]

Incessant vomiting may be due to uremia, and abdominal pain with vomiting has been seen "preceding uremic convulsions of puerperal nephritis."[7]

The importance of leucocytosis, if found, associated with localizing pain, during the first six or seven months of pregnancy, is considerable in making a diagnosis. Its value as far as indicating need of operation is apt to be overrated. "At the same time, leucocyte counts are valuable, and a rising count is of more importance than the absolute number."[8]

A constant, high leucocytosis (20,000 to 30,000) in appendicitis always points to the existence of a purulent process, providing there are no other complications to which the leucocytosis may be attributed. "In diffuse peritonitis the leucocyte count loses its certainty."[9]

Taken by itself, it is apt to be misleading, but taken in connection with other signs, it may be of great value in doubtful cases.

There is but one point in the diagnosis which I wish to emphasize: If there is cessation of pain without amelioration of local signs, operation is indicated at once.

The relief of tension brought about by perforation of the appendicular wall will be followed, in a few hours, by *an increase in the infected area, making the* results of an operation more doubtful.

The first case here reported is one of appendicitis complicating pregnancy, in which a gangrenous appendix was removed at three and one-half months, and in which, aside from a few uterine contractions set up by the removal of gauze drainage, on the fourth day proceeded to term and the patient had a normal confinement.

Case 1.—Mrs. L. W., aged 36, had been married three years.

History.—In October, 1900, gave birth to a son; labor was tedious, but aside from this there was nothing abnormal noted about the pregnancy or the puerperium. She became pregnant again in May, 1901. On Aug. 9, 1901, about 11 p. m., she was seized with a severe pain in the epigastrium, accompanied by nausea and vomiting; the bowels were and had been constipated; the symptoms continued through the night.

Examination.—Dr. H. W. Dudley of Abington was called on the morning of August 10; he found the patient with a temperature of 100 F., pulse 90. Pain was unremittent and the vomiting continued. There was marked rigidity of the abdominal muscles, especially on the right side, and the pain, worse at first in the epigastrium, had localized at McBurney's point. Hot fomentations were applied, and the same afternoon I saw her in consultation with Drs. Dudley Wheatley of North Abington and Osgood of Rockland, the two latter afterward assisting at the operation. At 5 p. m., when I saw her for the first time, the pain of which she had been complaining had in great measure ceased and there had been no nausea for some hours. Temperature was 100.5, pulse 110. Rigidity of the abdominal muscles was very marked, especially of the right rectus, and even moderate pressure over location of the appendix gave rise to pain. Believing that the cessation of pain without amelioration of local signs was not a favorable symptom, and not willing to temporize on account of the existing pregnancy, operation was advised.

Operation.—The usual preparations for an operation in a private house were made.[10] Under ether, a two-inch incision, afterward enlarged to three, was made through the outer border of the right rectus muscle. On opening the peritoneum, the appendix was found directly under the incision; it was dark colored, full of concretions and surrounded by purulent serum which was partially walled off by fresh adhesions of the omentum. Cloudy serum also welled up from the direction of the pelvis. This was carefully sponged out. The appendix was removed in the usual way, one strip of gauze packing was passed down to the stump and another strip passed down to drain the pelvis. The incision was closed by through-and-through sutures of silkworm gut, except for about an inch at lower angle of incision, through which the gauze drains were brought out.

Result.—From the time of operation until the gauze was removed, four days later, there was nothing out of the ordinary to report. After the packing was removed, the patient had two or three attacks of syncope which seemed quite threatening, accompanied by regular rhythmical pains, threatening abortion, but the pain was easily controlled by morphin sulphate administered subcutaneously, and the syncope was treated by alcoholic stimulation.

Subsequent History.—Recovery from this point was uneventful, and the patient was up in three weeks, the abdominal incision being entirely closed. Pregnancy continued until Feb. 26, 1902, when the patient was delivered of an eight-pound daughter. Labor was easy. There was no pain or bulging in the cicatrix from operation. In fact, there has been at no time during the pregnancy or puerperium any bulging of the scar.

Abortion, from conditions either present at the time of operation or which develop after such interference, adds much to the gravity of the prognosis.

Obstruction of the bowel or ileus is not uncommon, especially after operation for suppuration. Operation causes a change in the peritoneum, so that the clinical picture is entirely changed and the usual warning signs are absent.

Temperature and pulse with obstruction may be normal. There may be no marked distension, there may be continued vomiting of dark or fetal matter. There are no colicky attacks.

The most important diagnostic sign is dullness in the flanks, which progressively increases.

Next to this in importance is the facial expression, which, with obstruction, is drawn and anxious.

There is no pain and the patient is comfortable aside from the trouble of vomiting.

There is absence of marked abdominal rigidity.

Treatment consists in change of position, cathartics, followed by enemata, and large doses of atropin until appearance of toxic effects. If response to this treatment is not reasonably prompt, reopening of the wound, with incision of distended loops of intestine, followed in severe cases by tying a Mixter tube into the cecum will give the best results.

The second case was complicated by ileus. There was a fecal fistula and the abortion of a dead fetus. Recovery took place, with spontaneous healing of fecal fistula.

Case 2.—Dr. R. M. Birmingham, Lawrence, Mass.

Patient.—Mrs. S., aged 28; had been married six years. She has had four children; no accident or miscarriage. She has had no sickness other than periodical attacks of pain in the right iliac fossa during each pregnancy. With these attacks there was nausea, but all trouble was attributed to a growing uterus.

Present Illness.—About 5 o'clock on the morning of April 25, 1904, when she was about three months pregnant, she was seized with extremely sharp and colicky pains in the right iliac fossa; this was followed by collapse. Dr. Birmingham was called and advised immediate operation, to which the family would not agree until the afternoon of the same day.

Operation.—In the afternoon, assisted by Drs. Birmingham and Magee, I operated and found a gangrenous appendix surrounded by about two ounces of purulent matter. There was slight evidence of an attempt at walling off. A gauze drain was inserted. The vomiting, which had been present from the beginning, continued, but little distension developed.

[9] Goetjes: Münch. med. Wochft.
[10] Donoghue: Boston M. and S. Jour., Dec. 6, 1900.

Postoperative History.—The temperature remained between 99 and 100, but the pulse gradually increased in frequency. Considerable fecal matter and gas was discharged following enemas. Slight vomiting or rather regurgitation persisted.

On April 29, not satisfied with her condition and influenced by the facial expression, under chloroform, the gauze drain was removed. The omentum was found to be down to the region of the appendix stump; back of this was a loop of intestine greatly distended and containing liquid feces.

The adhesion was freed and the distended loops of the intestine incised, emptied and sewed up with continuous Lembert suture.

As symptoms of ileus persisted, on May 30, at 11 p. m., a Mixter tube was tied into the cecum. A saturated solution of salts was administered, followed by three ounces of alcohol and water.

On June 7, labor pains came on and following manual dilatation a dead fetus was extracted. A fecal fistula persisted for six months and then closed spontaneously.

Pain in the right iliac fossa, which increases as the uterus enlarges and pushes up out of the pelvis, should be looked on with great suspicion. Especially is this true of cases in which abortion comes on, following such pain.

A history of one or more such abortions should suggest surgical interference, even if the physical signs do not point definitely to the appendix.

OVARIAN TUMORS.

Tumors of ovarian or tubal origin are dangerous from their position, obstructing delivery, from torsion of the pedicle in the case of the former, or from inflammation.

A differential diagnosis between ovarian, tubal or uterine tumors, if the tumor is low down in pelvic cavity, is often difficult or impossible.

Extrauterine pregnancy presents such a varied clinical picture that it never can be excluded in making a diagnosis.

The acceptance of the dictum that "neoplasms, wherever situated, should, if possible, be removed, no matter what their apparent nature,"[11] would solve most of the difficulties we encounter in endeavoring to make an accurate diagnosis in pelvic conditions before advising operation.

Reposition of a pelvic tumor, with the patient in the knee-chest position, and with or without ether, while not being free from immediate danger, does not, in any way, point toward the removal of the underlying condition, unless the tumor proves to be an incarcerated uterus.

The danger of attempting reposition of an extrauterine pregnancy is sufficiently obvious, while rupture of a cyst and intraperitoneal hemorrhage from ruptured adhesions have been frequently reported.

The danger of torsion of the cyst during manipulation can not be ignored.

If ether is to be given for examination, preparations for operation should be made in case an operative condition is discovered.

While the question of when to operate in the presence of a tumor has been much discussed, there can be no doubt but that operation as soon as diagnosis is made, will yield the best results, unless, indeed, a small tumor, which has given rise to no symptoms, be discovered late in the pregnancy. Even then, the patient should be carefully watched after delivery to see that torsion, rupture or degeneration of tumor from changed blood supply does not take place.

The most common cause of trouble with ovarian tumors, during pregnancy, is torsion of the pedicle. This may take place at any period of pregnancy, and is accompanied by an increase in size and tenderness over the tumor, while a sharp, stabbing pain is referred to the spot at which the torsion takes place. "This is sometimes accompanied by slight bleeding and bleeding pains."[12]

Under these conditions, prompt removal of the tumor is indicated and is followed by cessation of symptoms referred to the uterus. It will add little, if any, to the maternal danger should miscarriage follow.

Graefe,[12] in a study of 178 cases of ovariotomy, undertaken during pregnancy, found that the mortality of the mothers in the entire list was 2.3 per cent. One of the deaths occurred three months after the intervention, and one death was inevitable, as extensive gangrene was found during the operation. The last 126 operations contain only this one fatality. In 119 cases the pregnancy was interrupted by the intervention in only 19, or 16 per cent. In the last series of 27 abortion followed in 5 and premature delivery in 3. This series includes the American cases of Jarman and Kahn. The pregnancy continued undisturbed in two cases, in which there were numerous adhesions or torsion of the pedicle of the tumor. In the cases in which abortion occurred, there must have been some predisposition to it, possibly from decidual endometritis as the trauma of the intervention was slight. Abortion would probably have occurred without the operation. The statistics show that ovarian tumors, during a pregnancy, induce abortion in 17 per cent. of the patients if left unoperated on. After ovariotomy, the pregnancy was interrupted in only 22.5 per cent., and a third of this number presented urgent invitations for surgical relief. The results of expectant treatment have been a maternal mortality of 39.2 per cent., and a fetal of 67 per cent., according to Orgler's and Winckel's statistics. Six of the cases in the series demonstrate that even after evidences of intending abortion have appeared, prompt ovariotomy will afford relief, and the pregnancy will continue its course uninterrupted.

Heil[13] adds to Graefe's statistics five new cases personally observed, and others he has collected, bringing the total to 241. He tabulates the later series, and emphasizes the necessity for careful examination of every pregnant woman who complains of pains or other disturbance indicating some irregularity in the genital sphere. If the diagnosis wavers between extrauterine pregnancy and intrauterine pregnancy with an ovarian cyst, a laparotomy is indicated at once. An ovariotomy is by far a lesser evil than the overlooking of an extrauterine pregnancy, especially for a patient who is not under constant medical supervision. He advocates leaving the tube, if possible, when operating during a pregnancy, to avoid traction on the uterus.

In case a tumor is discovered at parturition, obstructing delivery or impacted in the pelvis, the treatment should be Cesarean section, followed by removal of the tumor.

CASE 3.—Dr. R. M. Birmingham, Lawrence, Mass.

Patient.—Mrs. M., aged 29, had been married three years at the time of operation.

---

[11] Richardson: THE JOURNAL A. M. A., Jan. 9, 1904.

[12] Graefe: Munich. Med. M. A., Oct. 28, 1902.

[13] Heil: Munch. Med. Ma. February, 1904.

History.—She had one other child, no miscarriages. During the first pregnancy she had severe pain from the beginning, and morphin sulphate in doses of gr. 1/12 was given subcutaneously from time to time. After delivery a tumor to the left of the median line was discovered. Some time after this confinement she had severe pain in the abdomen, followed by nausea and vomiting, and went to the Carney Hospital for treatment. Another pregnancy was suspected, and she was sent home with instructions to report later. Eleven weeks after returning from the hospital she had sudden colicky pain in abdomen and increase in the size of the tumor.

She had been uncomfortable for two or three days, and woke early on the morning of April 19, 1904, with a sudden, sharp, severe, stabbing pain in the lower part of the abdomen. She had nausea and vomited once. Her face was drawn. A large movable tumor, the size of a child's head, could be easily outlined in the lower right quadrant of the abdomen. Temperature was 99, pulse 110.

Operation.—Incision was made through the left rectus muscle. A large ovarian cyst, dark and hemorrhagic, from twisting of pedicle, was removed from the left side. A long free appendix containing a concretion was also removed. Recovery from operation was uneventful. The patient was out of bed on the fourteenth day. On Dec. 12, 1904, she was confined in an uneventful labor and delivered of a boy. There was no bulging in the scar and abdominal wall is perfectly solid.

Retarded menstruation, sharp, colicky and abdominal pain, and a growing tumor in the neighborhood of the uterus, strongly suggest extrauterine pregnancy, and that condition should be borne in mind in making an operative diagnosis.

As a positive diagnosis can only be made after the abdomen has been opened, there is little justification for delay.

If, at the operation, an enlarged tube, which does not prove to be impregnated, is found; or a small cyst of the ovary, which may be resected without difficulty, the patient has suffered in no way from the operation. On the other hand, the chance of a serious crisis, if the case be one of extrauterine pregnancy, should far outweigh any objection to surgical interference.

Case 4.—Patient of Dr. W. G. Brown, Plymouth, Mass., was seen Oct. 5, 1904, at the Jordan Hospital.

Patient.—Mrs. C., ten weeks pregnant.

History.—For eight weeks previously she had had increasing nausea, until nothing solid or liquid was retained. The smell of food caused severe retching with great pain. There had been severe pain in the right iliac region since the nausea began.

Vaginal Examination.—To the right and back of the uterus a tumor the size of a hen's egg could be felt, extremely tender, and causing great pain when pressed on.

Operation.—Assisted by Dr. E. D. Hill of Plymouth, I opened the abdomen and removed a prolapsed cystic left ovary. The uterus was also caught forward by two sutures to the abdominal wall.

Result.—There was good recovery from operation. The nausea and pain were immediately relieved. The patient left the hospital in three weeks, and nothing unusual took place during rest of pregnancy.

On May 24, 1904, after a labor of fourteen hours' duration, she was delivered normally of a male child, weighing 7½ pounds. The labor was in every way normal, and much more comfortable than the former one, the woman having had one child previous to this pregnancy.

FIBROIDS.

When pedunculated, fibroids closely simulate ovarian tumors, and are liable to the same kind of accidents, while subperitoneal or interstitial fibroids may cause trouble in various ways. Change in the tumor itself, or in its relations, and the cardiac, vascular and nephritic changes which take place with tumor development, all make for early operation, at least during the childbearing ages.

Dr. Franklin H. Martin,[14] in an analysis of 1,188 cases of operation for fibroids, at the hands of A. Martin, Noble, Cullingworth, Frederick, Scharlieb, and a series reported by Kanner and by McDonald, to which he adds 200 of his own, forcibly shows the difficulty of exact diagnosis and notes the presence of unrecognized, serious complications, diagnosis of which was only possible by operation.

In the 1,388 analyzed cases presented in his paper, the operations revealed 32 cases of carcinoma of the body of the uterus, 24 cases of unsuspected sarcomas of the uterus, 70 cases of necrosed tumors, which were very liable to become infected and to cause death, 53 cases of intraligamentous development of the tumor, which are so liable to produce kidney complications by ureteral pressure, and many other serious symptoms; 8 adenomyomas, 2 pregnancies menacing the life of the patient; 5 ectopic pregnancies, 8 dermoid cysts, 97 suspected or unsuspected true ovarian cysts, 12 parovarian cysts, 72 cases of pyosalpinx, 20 cases of appendicitis, 7 cases of intestinal obstruction, 2 cases of acute intestinal obstruction, 2 cases of obstructed ureters, 2 cases of hydronephrosis from pressure.

In this list these serious conditions, incurable without operation, and unsuspected in the majority of instances, represented 31.6 per cent. of all patients operated on. This is the most instructive and startling thing about this analysis. Nearly one-third of all the cases in which operation was performed were complicated with conditions very liable to prove fatal. This does not take into consideration serious symptoms, the size of the tumors and the various degenerations which are not necessarily fatal, and which are set forth in the same table.

When we take into consideration symptoms, as shown in his 200 cases, we have interesting food for contemplation. Dangerous hemorrhage occurred in 41 cases, or 20.5 per cent.

Whether or not it is antecedent sterility that is the important causative factor in the growth of fibroids, or whether the fibroid condition is the cause of the sterility, the fact remains that fibroids are often found complicating pregnancy. The management of a pregnancy, so complicated, depends on the size and situation of the tumor. This increase in size of the tumor is due simply to its taking part in the hypertrophy common to the uterus.[6]. During pregnancy fibroids almost invariably become flattened.

"The most important or most fortunate change which may take place in the fibroid, irrespective of whether or not it is interstitial, subserous or submucous, is the development of edema with resulting softening."

This allows a subserous tumor, if situated within the pelvis, to slip out past the presenting head, causing the disappearance of apparently hopeless obstruction, and allowing a normal delivery; or it may be compressed into a thinner and broader mass and thus allow the free passage of the child.

After the labor, the fibroid again resumes its prominent shape.

In the great majority of cases, the fibroid in the latter months of pregnancy so changes its location as to leave the pelvic canal free for the passage of the fetus.

---

[14] N. Y. Med. Jour., June 17, 1905.

Remarkable examples of this are reported in cases in which the tumor filling the whole of the true pelvis has risen spontaneously out of the pelvis and normal labor has occurred.

Hamilton[15] records a very rare case, in which he was called to a woman after labor, in whose uterus the presence of two subperitoneal myomata had already been diagnosed. Dr. Scott had delivered the child and placenta without difficulty, but some twenty hours afterward was sent for in a hurry, on account of the sudden collapse of the patient. He diagnosed intraperitoneal hemorrhage and sent for Dr. Hamilton. The patient was blanched and restless, the abdomen was tympanitic, and an area of dullness had rapidly formed in the right flank.

Abdominal section was performed, and on opening the peritoneal cavity a large quantity of blood escaped. In searching for the source of this bleeding, a ruptured vein of large size was found on the surface of one of the subperitoneal myomata, from which blood was freely escaping. The myoma was enucleated.

Examination showed that a piece of omentum had become adherent to the capsule of one of the tumors. Uterine contractions had probably separated this omental attachment and opened the vein. Good recovery ensued. He mentions that six members of this patient's family had suffered from myomas of the uterus.

Fibroids rarely become necrotic during pregnancy, but cases sometimes occur in which the tumor breaks down in the center, peritoneal adhesions sometimes form and may cause incarceration and abortion.

Dr. Carmalt[16] reports a very interesting case of complicated uterine fibromyoma. Operation was performed and the patient recovered and subsequently became pregnant.

That portion of the history of the case which is of interest in connection with consideration of danger at deliveries follows:

> After three miscarriages, the patient became pregnant in May, 1902. By that time it was apparent that there was a large, rapidly growing fibromyoma or myomata, in the anterior wall of the cervix, and lower uterine segment pressing on the bladder, as well as filling the upper vagina so completely that the cervix could not be reached. The patient declined to have labor induced, and we decided to do Cesarean section whenever labor commenced, the period of pregnancy being very doubtful. Preparations were made and labor commenced, but before the arrival of assistants the uterine contractions lifted the tumor out of the pelvis and drove the child down to the perineum. Although this took place in less than half an hour, the length of the vagina was so great that the child was asphyxiated before I delivered it. Faithful, artificial respiration, hot and cold water, and stimulation failed to restore breathing. The patient's convalescence was uninterrupted, and the tumor (apparently the size of a child's head) shrank to less in size than a small egg. (Afterward it grew rapidly.) Oct. 25, 1903, celiotomy performed. The tumor was found occupying the anterior wall of the uterus, encroaching on the bladder below and extending into the left broad ligament. There was no pedicle, myomectomy was performed and the patient recovered and subsequently became pregnant. She was delivered Sept. 15, 1904, of a 10¼-pound boy.

It is the experience of obstetricians that "labor very seldom finds one of these tumors in the way," and this should make us conservative about operation during the latter months of pregnancy unless symptoms of pressure appear.

Dr. Mixter,[17] in the report of the first case in this country of Porro operation for multiple myomata, in which mother and child were saved, reported the condition of the pelvic outlet as follows:

"Examination showed a solid, immovable mass, filling nearly the whole pelvis. The finger could with difficulty be passed between this and the pubes and a partially dilated os could be felt. This in spite of the fact that the woman, while in labor, had travelled a hundred miles to reach the hospital."

Since the report of this case, a large number of similar cases treated in like manner, have been reported by various operators, and suggest that when a diagnosis of tumor is made, the general practitioner should send for his usual operating consultant rather than for other obstetrical help.

The pedicle of a subserous fibroid occasionally undergoes torsion during pregnancy, followed by peritonitis and interstitial hemorrhage. This gives rise to symptoms which may be obscure and accurate diagnosis may be possible only at operation, as in the following case:

Case 5.—Dr. A. A. MacKeen, Whitman, on Dec. 5, 1904, was called to New Hampshire to see Mrs. L., aged 34, who had been married the previous June.

History.—She had had persistent nausea and vomiting for three months, and obstinate constipation. She had menstruated last on September 24. She had a violent hemorrhage October 24, lasting only for a few minutes, and followed by intense pain in the lower epigastric region, with great weakness.

Examination.—On examination, Dr. MacKeen found a large mass occupying the posterior portion of the pelvis, immovable or only slightly movable. The os was slightly patulous.

Diagnosis and Treatment.—He formed the opinion that she was probably pregnant and had a fibroid. Possibly an ectopic gestation with early rupture. He had her brought to her home in Whitman. I saw her with Dr. MacKeen on December 10, and performed abdominal section, removing a large pedunculated fibroid from the posterior wall of the uterus. The patient made a good recovery. She was up three weeks after the operation. There was no amount of uterine pain after operation. The constipation was somewhat relieved, and the nausea and vomiting were entirely cured. She had an uneventful confinement on July 4, 1905.

Fibroids present in a uterus after the age of 40 may give rise to symptoms which are sometimes attributed, before operation, to an increase in size or to a change in the character of the uterine growth. Operations have been repeatedly done under these conditions, and a pregnancy found as the basis for the apparent lighting up of the growth.

One case of mine was of this character, and there appears to be no way surely to escape from this error in diagnosis.

On moral grounds, the induction of labor early in pregnancy has no justification whatever. It is fully as serious as the performance of an operation to relieve the condition which complicates the pregnancy, and in the great majority of cases the pregnancy will continue to term.

CONCLUSIONS.

When there is a history of a well-marked attack of appendicitis in a young woman, operation should be performed as an antecedent to marriage.

With well-marked, acute symptoms, referable to the right iliac fossa, in the presence of pregnancy, operate at once.

---

[15] Australian Med. Gaz., April 20, 1904.

[16] Am. Jour. of Obstetrics, January, 1905.

[17] Mixter: Boston, M. and S. Jour., Nov. 8, 1888.

History.—She had one other child, no miscarriages. During the first pregnancy she had severe pain from the beginning, and morphin sulphate in doses of gr. 1/12 was given subcutaneously from time to time. After delivery a tumor to the left of the median line was discovered. Some time after this confinement she had severe pain in the abdomen, followed by nausea and vomiting, and went to the Carney Hospital for treatment. Another pregnancy was suspected, and she was sent home with instructions to report later. Eleven weeks after returning from the hospital she had sudden colicky pain in abdomen and increase in the size of the tumor.

She had been uncomfortable for two or three days, and woke early on the morning of April 19, 1904, with a sudden, sharp, severe, stabbing pain in the lower part of the abdomen. She had nausea and vomited once. Her face was drawn. A large movable tumor, the size of a child's head, could be easily outlined in the lower right quadrant of the abdomen. Temperature was 99, pulse 110.

Operation.—Incision was made through the left rectus muscle. A large ovarian cyst, dark and hemorrhagic, from twisting of pedicle, was removed from the left side. A long free appendix containing a concretion was also removed. Recovery from operation was uneventful. The patient was out of bed on the fourteenth day. On Dec. 12, 1904, she was confined in an uneventful labor and delivered of a boy. There was no bulging in the scar and abdominal wall is perfectly solid.

Retarded menstruation, sharp, colicky and abdominal pain, and a growing tumor in the neighborhood of the uterus, strongly suggest extrauterine pregnancy, and that condition should be borne in mind in making an operative diagnosis.

As a positive diagnosis can only be made after the abdomen has been opened, there is little justification for delay.

If, at the operation, an enlarged tube, which does not prove to be impregnated, is found; or a small cyst of the ovary, which may be resected without difficulty, the patient has suffered in no way from the operation. On the other hand, the chance of a serious crisis, if the case be one of extrauterine pregnancy, should far outweigh any objection to surgical interference.

CASE 4.—Patient of Dr. W. G. Brown, Plymouth, Mass., was seen Oct. 5, 1904, at the Jordan Hospital.

Patient.—Mrs. C., ten weeks pregnant.

History.—For eight weeks previously she had had increasing nausea, until nothing solid or liquid was retained. The smell of food caused severe retching with great pain. There had been severe pain in the right iliac region since the nausea began.

Vaginal Examination.—To the right and back of the uterus a tumor the size of a hen's egg could be felt, extremely tender, and causing great pain when pressed on.

Operation.—Assisted by Dr. E. D. Hill of Plymouth, I opened the abdomen and removed a prolapsed cystic left ovary. The uterus was also caught forward by two sutures to the abdominal wall.

Result.—There was good recovery from operation. The nausea and pain were immediately relieved. The patient left the hospital in three weeks, and nothing unusual took place during rest of pregnancy.

On May 24, 1904, after a labor of fourteen hours' duration, she was delivered normally of a male child, weighing 7½ pounds. The labor was in every way normal, and much more comfortable than the former one, the woman having had one child previous to this pregnancy.

FIBROIDS.

When pedunculated, fibroids closely simulate ovarian tumors, and are liable to the same kind of accidents, while subperitoneal or interstitial fibroids may cause trouble in various ways. Change in the tumor itself, or in its relations, and the cardiac, vascular and nephritic changes which take place with tumor development, all make for early operation, at least during the child-bearing ages.

Dr. Franklin H. Martin,[14] in an analysis of 1,188 cases of operation for fibroids, at the hands of A. Martin, Noble, Cullingworth, Frederick, Scharlieb, and a series reported by Kanner and by McDonald, to which he adds 200 of his own, forcibly shows the difficulty of exact diagnosis and notes the presence of unrecognized, serious complications, diagnosis of which was only possible by operation.

In the 1,388 analyzed cases presented in his paper, the operations revealed 32 cases of carcinoma of the body of the uterus, 24 cases of unsuspected sarcomas of the uterus, 70 cases of necrosed tumors, which were very liable to become infected and to cause death, 53 cases of intraligamentous development of the tumor, which are so liable to produce kidney complications by ureteral pressure, and many other serious symptoms; 8 adenomyomas, 2 pregnancies menacing the life of the patient; 5 ectopic pregnancies, 8 dermoid cysts, 97 suspected or unsuspected true ovarian cysts, 12 parovarian cysts, 72 cases of pyosalpinx, 20 cases of appendicitis, 7 cases of intestinal obstruction, 2 cases of acute intestinal obstruction, 2 cases of obstructed ureters, 2 cases of hydronephrosis from pressure.

In this list these serious conditions, incurable without operation, and unsuspected in the majority of instances, represented 31.6 per cent. of all patients operated on. This is the most instructive and startling thing about this analysis. Nearly one-third of all the cases in which operation was performed were complicated with conditions very liable to prove fatal. This does not take into consideration serious symptoms, the size of the tumors and the various degenerations which are not necessarily fatal, and which are set forth in the same table.

When we take into consideration symptoms, as shown in his 200 cases, we have interesting food for contemplation. Dangerous hemorrhage occurred in 41 cases, or 20.5 per cent.

Whether or not it is antecedent sterility that is the important causative factor in the growth of fibroids, or whether the fibroid condition is the cause of the sterility, the fact remains that fibroids are often found complicating pregnancy. The management of a pregnancy, so complicated, depends on the size and situation of the tumor. [16] Am. Jour. of Obstetrics, January, 1905.

[17] Mixter: Boston, M. and S. Jour., Nov. 8, 1888.

The same treatment should be applied when there is gradual increase of marked discomfort in the same region.

Operation should be advised, prior to marriage, if tumors of the uterus or appendages are known to be present.

The treatment of ovarian or uterine tumors, not recognized until pregnancy has occurred, should be governed by the conditions existing in the individual case.

At or near term, an operation may be performed which will remove the condition and, at the same time, permit the delivery of the child.

409 Marlborough Street.

DISCUSSION.

Dr. E. E. Montgomery, Philadelphia, is fully in accord with the conclusions drawn by Dr. Donoghue. There is no question, he said, that the existence of an appendicitis in a pregnant woman is a source of serious danger, and the fact that she has had repeated attacks of chronic appendicitis should be an indication for operation in the early stage of the pregnancy. The danger arising from an operation during the period of quiet would be far less than the patient would incur by continuing the possibility of the development of serious complications during the later stages of pregnancy. Dr. Montgomery has operated on such patients a number of times and the majority of them have done well. One woman had to be operated on during the seventh month of pregnancy. She miscarried, but recovered and has since given birth to two children. He also agreed with Dr. Donoghue in regard to operating on myomata. In many cases one can not tell what changes may take place during pregnancy, and unless the tumor is in the pelvis and interferes greatly with the circulation it is better to wait to see whether Nature is not able to lift the tumor out of the pelvis so as to be out of the way at the time of delivery. The presence of a growth of considerable size in the uterus may be the source of considerable trouble during delivery as the result of irregular contraction. Owing to the increased nutrition in the uterus, these tumors also grow rapidly, and sometimes it becomes necessary to operate in the later stages of a pregnancy on account of the discomfort and the danger of loss of life because of the size of the tumor. In cases in which the patient comes under observation prior to the fourth month of pregnancy and the tumor is of good size and situated in the lower arc of the uterus, it is preferable to open the abdomen and to enucleate the growth. Dr. Montgomery has done this in five patients, all of whom went on to term and were delivered without any unpleasant symptoms; nor did they suffer any discomfort or inconvenience during the convalescence. He also agreed with Dr. Donoghue that when an ovarian tumor complicating pregnancy is below the uterus it is certain to be a source of difficulty in the delivery. It may be possible to evacuate the contents of the tumor through the vagina, but by so doing the patient is subjected to several dangers. Its contents may be of such a character as to give rise to a serious peritonitis complicating the puerperium. It may be of the papilliform variety. If the tumor does not rupture, the pressure to which it is subjected may cause necrosis and the development of serious trouble during the puerperium requiring operative interference and endangering the life of the patient. For these reasons, if the tumor is situated in the pelvis below the developing uterus, the operation should be done as early in the pregnancy as possible. The danger to the patient is less than if we wait to see what Nature will do.

Dr. Charles S. Bacon, Chicago, said that he is particularly interested in the matter of ovarian tumors complicating pregnancy, having had some experience with these cases. He thinks that there is no doubt that all ovarian tumors should be removed as soon as they are diagnosticated, with the exceptions made by Dr. Donoghue. The possibility of the rapid growth of the tumor during the pregnancy, which is very common, the danger of pressure symptoms which result from that, and especially the great danger of disturbance of the puerperium, twisting the pedicle and interfering with the circulation, lead to this conclusion. When the tumor is discovered during labor, however, Dr. Bacon is not certain that the advice to operate at once is best. There is a different condition here, and it would seem that large tumors that fill the pelvis can be replaced fairly easily and safely by making use of the knee-chest position or the Trendelenburg posture, with anesthesia if necessary. The tumor usually can be replaced and labor go on. The case must be watched, and, when symptoms supervene, operation should be done. In fibroids, his experience is against operation, even in the early months of pregnancy. The serious complications in fibroids are not so common as one would expect, and very rarely do they become troublesome during delivery. If the tumor is not situated in the cervix or in the lower uterine zone, he thinks it is best to let it alone.

Dr. J. H. Carstens, Detroit, said that when he was an obstetrician he met quite a few cases of tumors of various kinds in which the patients died during delivery or shortly afterward, and it always impressed him strongly that these tumors should be removed. When he became an abdominal surgeon, he advocated the removal of these tumors, and some years ago he reported a few cases. An adherent tumor in the cul-de-sac can not be replaced; it must be removed, and as early as possible. A fibroid in the broad ligament growing rapidly, as these generally do, must be removed. A fibroid in the lower segment of the uterus or in the cervix, or at about the situation of the internal os, can often be removed through the vagina by lifting it up completely and enucleating the tumor. Of course, in cases of extrauterine pregnancy and appendicitis there is no question about operating during pregnancy. Strangulated hernias occurring during pregnancy must be operated on. Dr. Carstens had about thirty cases of operations during pregnancy, and he has found that women will stand an operation during pregnancy as well as at any other time. In fact, he believes that they usually stand it better. If the fibroid is down deep, a submucous fibroid, one can not tell beforehand how deep he is going down. The tumor may be over the site of the placenta, and the operator may cause some interference with the circulation of the placenta, producing fatty degeneration, and, as a result, an abortion takes place. Many more women die with tumor during pregnancy and labor than die if operated on promptly. Fibroids that are loose and movable and that are located above the brim of the pelvis, or that are subperitoneal, do not interfere with delivery. The woman will be delivered all right, and the tumor can be removed afterward. Sometimes, during subinvolution, these fibroids will be absorbed, but only in very rare cases.

Dr. W. B. Dorsett, St. Louis, emphasized the remarks made by Dr. Carstens, and related a case that occurred in his practice three years ago. A woman consulted him, complaining of much pain in the pelvis. She thought she was about three months' pregnant. On examination Dr. Dorsett found an incarcerated uterus, with a fibroid tumor of conical shape behind the promontory of the sacrum. He recognized that the woman was pregnant and operated. After opening the abdomen he lifted the entire mass, tumor and uterus, out of the pelvis, and on examining the tumor he was satisfied that it dipped down deep into the uterine wall, so he thought it best not to remove it. The woman went on to term and was delivered. The tumor now is not larger than a walnut, so, he thinks, we ought to speak conservatively about enucleation of fibroid tumors during pregnancy, because one can not always tell how deep they dip into the uterine wall. He operated not long ago on a case of ovarian tumor cyst in which pain was severe and that really demanded operation. The case had been deemed one of appendicitis for a number of years. He removed a small cyst from the right side. The woman recovered from the operation, but aborted in the fourth month. Conservatism should guide us in these cases in which fibroids complicate pregnancy.

Dr. F. D. Donoghue said that surgeons see so many end results of these cases following delivery, especially cases of sloughing fibroids with such a high mortality, that they are apt to be more radical in advising interference than the obstetrician, who only occasionally has a fatal case. Regarding the treatment of the cyst by puncture, in the last seven years

Dr. Donoghue has never punctured an ovarian cyst. Malignant disease of the peritoneum is not uncommon following the puncture of a cyst which may appear benign. The danger of the large incision is much less than the danger of dissemination papilloma of the ovary by puncture.

NERVOUS AND MENTAL MANIFESTATIONS OF PRE-PERNICIOUS ANEMIA.*

F. W. LANGDON, M.D.
CINCINNATI, OHIO.

Most practitioners of wide experience have probably been puzzled at times by a class of patients presenting an anomalous grouping of general and nervous symptoms, which have passed from one physician to another; perhaps labelled as "general debility" by one, "neurasthenia" by another, "crankiness" by a third, "hysteria" by others; cases which steadily progress toward a fatal termination in spite of supporting treatment, "rest cures" and optimistic prognoses.

Occasionally a residence for a more or less prolonged period in a well-equipped hospital, or an accidental falling into the hands of some young "up-to-date" village doctor, leads to a routine blood examination and the surprising discovery is made that the patient has "pernicious anemia."

During the past decade it has fallen to my lot to have under observation a number of such patients, whose chief complaints were of a distinctly mental and nervous character, and who in the course of time were found to present the characteristic blood state and somatic phenomena of pernicious anemia.

In some the nervous and mental departures were attributable to preceding or accompanying blood defect; in others, however, distinct evidence of organic nervous changes of degenerative type preceded the actual development of the pernicious feature of the anemia. These latter cases tend to raise again the questions, which have not by any means been satisfactorily answered:

1. Does the impaired enervation at times lead to morbid functioning in the blood-forming or blood-destroying organs?
2. Does the blood deterioration lead to the nervous phenomena?
3. Is there a common cause for the nervous symptoms and the blood deterioration?

It would seem to me probable that the last question will eventually be answered in the affirmative. In a few cases the opportunity has been offered to follow their development from so-called *"secondary anemia"* to an anemia of "pernicious" type as shown by the blood test.

SYMPTOMATOLOGY.

Analyzed clinically these cases collectively have seemed to present a rather characteristic syndrome, the occurrence of which may be of diagnostic and prognostic import.

In its full development, this syndrome may be characterized as follows, though individual cases may be incomplete as regards one or more symptoms, as would naturally be expected:

1. General ill health.
2. Mental symptoms, viz., loss of inhibition, peevishness and gradual mental deterioration, varied however, by control, patience, good temper, etc., for longer or shorter intervals.

Two of my cases, both women, presented this variability to a remarkable extent, the mental picture changing abruptly for better or worse within a few hours.

During the "better" periods some patients are almost "angelic" in disposition and conduct.

One patient had a distinct history of auditory hallucinations.

3. Sensory disturbances: (a) Subjective, consisting of intramuscular and articular pains. The former are never, in my experience, of "lightning" character as in tabes, but rather of the nature of "aches" or dull pains.

The articular pains are seldom accompanied by effusions and never by true inflammatory action, heat, redness, etc.

Other subjective sensory complaints which are perhaps more frequent than the above are sensations of numbness, tingling and weight in the extremities, usually more marked in the feet and legs. These symptoms, with the ataxia noted later, have occasionally led to an erroneous diagnosis of tabes, as in Case 1.

(b) Objective sensory disturbances: These are common and consist chiefly of losses of tactile and pain sensibility about the feet and ankles; "patchy" in distribution, *i. e.*, *not* segmental. Sometimes in the earlier stages only delay in transmission of sensation may be found. Tabes is excluded in these cases by the often exaggerated knee jerks and spastic gait, as well as by the absence of pupillary changes.

4. Plus knee jerks, ankle clonus and "Babinski sign" (extensor plantar reflex) are present in some cases.
5. Ataxia of gait and station is often present.
6. Diarrhea of the mucous type is apt to occur sooner or later.
7. The peculiar "lemon yellow" tint of pernicious anemia occurs in the advanced stages.

A combination of all or a majority of the above symptoms should suggest the possibility of an anemia of pernicious or prepernicious type and a careful blood examination may lead to a correct diagnosis and prognosis.

CASE 1.—Mrs. J. S. M. was seen Sept. 12, 1898. She complained of peculiar feelings in fingers and feet, with stiffness of legs, all of two years' duration.

History.—A diagnosis of locomotor ataxia had been made. This was negatived by the entire absence of either Argyl Robinson pupils or lightning pains and the presence of hyperactive knee jerks. The patient's father died of consumption, her mother was epileptic. The patient had been married sixteen years, but had never been pregnant. Syphilis, alcoholism lead and diabetes were excluded in the history. She had been sent south for lung disease in adolescence, with resulting recovery.

Examination.—Woman under average height; general nutrition apparently fair, distinctly anemic to the eye; pulse 96, small; no heart lesion. She was mentally logical, but apprehensive, and was emotionally depressed. There were no cranial nerve palsies or defects; no lightning pains; no defect of pain sense at ankles and feet.

Motor Powers: Patient can walk fairly well. Her gait is ataxic and slightly spastic. Legs "draw up" at night and knees are tightly flexed when she awakes.

Grasp: R. 45 kilos., L. 32 kilos., by Matthieu dynamometer (estimated at about 60 per cent. of normal). There was some ataxia of hand and arm movements.

Reflexes: Triceps was superactive and wrist jerks active. Knee jerks were present, slightly exaggerated.

Remarks.—A diagnosis of "probable combined sclerosis" of Putnam-Lichtheim-Dana type was made. Opportunity for blood examination was *not obtained*, as the patient was going away to a health resort, where she gradually lost strength in spite of careful supporting treatment, and died in about three months.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The physician, under whose care she was, writes me that he concurred in the diagnosis of "combined sclerosis," and that the reflexes toward the end were "practically entirely lost."

While the diagnosis of pernicious anemia in this case may justly be open to criticism, owing to the absence of blood examination, yet the clinical features, evident anemia, the steady deterioration in strength and the fatal issue in a little more than two years, together with the absence of other disease of lethal nature, would all seem to render the presence of the morbid blood state extremely probable.

Case 2.—This case has already been reported in The Journal, March 2, 1901. A brief abstract is as follows:

History.—A. W. C., male, aged 34, American, married, no children, hospital supervisor and restaurant proprietor by occupation, was under observation from July, 1899, to the fatal termination of his illness in April, 1900. There was a history of three or four years' gradual failure of health, preceding actual illness.

Examination.—Syphilis was excluded. His habits were good. He complained of weakness and rigidity in legs, and was unable to walk without assistance from others.

Sensory and Motor Symptoms: There were defects of tactile and pain senses about ankles, and delay and hypesthesia in both, without actual anesthesia. There was motor weakness with rigidity of legs and inability to walk. There was also inco-ordination in the upper and lower extremities.

Reflexes: Knee jerks were plus. Ankle clonus was present on both sides. Plantar reflexes were of the distinct "Babinski" type.

There was no notable mental defect until twenty-four hours before death, when coma appeared.

Mucous stools were a marked symptom during the last few weeks. Also epistaxis.

Blood Counts, July 8, 1899 (Dr. M. A. Brown): Reds, 1,279,440; whites, 3,600; hgn., 32 1/6 per cent.; color index, 1.3; poikilocytosis, marked; nucleated reds numerous; megaloblasts more numerous than normoblasts.

Second Count, Feb. 13, 1902 (at pathologic laboratory, City Hospital): Reds, 1,661,805; whites, 3,000; hgn., 54 per cent.; color index, 1.54; eosinophiles, 9 per cent.; neutrophiles, 49 per cent.; small lymphocytes, 39 per cent.; large lymphocytes, 3 per cent.; piokilocytosis was not marked; megaloblasts, three seen.

Subsequent examination showed no material change.

Autopsy.—Autopsy and microscopic investigation by Dr. Wolfstein showed the typical cord lesion of Putnam-Dana type of combined sclerosis.[1]

Case 3.—J. W. D., man, aged 34, single, active business man, was seen Jan. 7, 1898, in consultation with Dr. G. W. Wire of Wilmington, Ohio.

History.—He has complained of "tired feeling" for past two months. He had a crop of "dry boils" from waist to knees, about three months previous to this examination. Family history is good. There is no syphilis. Anemia was evident. Bilateral hydrothorax was present. There was no ataxia or rigidity of limbs present and no defect of tactile or pain senses was noted.

Reflexes: Knee jerks were lively. Ankle clonus was absent. Plantar reflex was not noted.

Blood Count (Dr. W. E. Schenck): Reds, 1,200,000 (4 counts); whites, 4,000; hgn., 35 per cent.

Subsequent History.—I am indebted for the subsequent history of the case to Dr. Wire, who writes me that the patient did fairly well for five or six months, then rapidly weakened, but was not absolutely confined to his home until seventeen days before his death on Nov. 26, 1898.

Death was due to cerebral hemorrhage, preceded by retinal hemorrhages, which abolished vision.

Case 4.—C. H. L., aged 57, business man and capitalist, married, four children, was seen April 18, 1903, in consultation with Dr. J. H. Landis.

History.—Family history was good. His habits were good. There was no syphilis and no previous illness of consequence. He complained of peculiar feelings in hands ("as of cornmeal on them") and in feet (as if resting on a sponge). The duration of these symptoms was six months.

Examination.—He had a large frame, full habit; height, 6 feet; weight, 212 pounds. He was moderately anemic to the eye. Heart sounds were not sharp. There were no urinary symptoms. Pupils responded to light, but somewhat sluggishly.

Motor Apparatus: There was no palsy; no inco-ordination. Power was reduced in grasp, i. e., R. 66 kilos., L. 60 kilos (normal estimated at about 90).

Re-examination twelve days later showed R. 75k., L. 60k. by same dynamometer.

Sensation: There were no losses of tactile or pain senses and no obvious delay in transmission.

Reflexes: Knee jerks were good and equal.

Blood examination (Dr. W. E. Schenck): Reds, 3,016,000; whites, 6,400; hgn., 60 per cent.; color index, 1 per cent.; differential count; polymorphonuclears, 80 per cent.; young, 16 per cent.; eosinophiles, 4 per cent.; the reds were irregular in snape and size. Diagnosis was secondary anemia (erythrocytemia).

Subsequent History.—Patient was put on iron, arsenic and supporting treatment and sent to the seashore, where he appeared to improve for a time. Growing worse later, the blood was re-examined and a diagnosis of pernicious anemia was made.

Blood Examination, March 2, 1904 (Dr W. E. Schenck): Reds, 1,000,000; whites, 4,360; hgn., 25 per cent.; color index, 1.5 differential count, whites, polymorphonuclears, 81 per cent.; small lymphocytes, 16; large lymphocytes, 3; poikilocytosis, chromatophilia, microcytes and macrocytes.

Diagnosis: Pernicious anemia.

At this time Dr. Landis informs me there was spastic gait, plus knee jerks, and "Babinski" plantar reflexes; also some diarrhea of mucous type and loss of control of rectal sphincter with retained power over bladder. There were no mental defects. The fatal termination occurred about one year from the time of his first visit.

Case 5.—A. H., financier and man of affairs, aged 67, very active, married, with several children living and healthy, was seen in June, 1902, in consultation with Dr. H. K. Dunham.

History.—His only complaints were of numbness and coldness in fingers (both hands), and pain in right shoulder. He called it rheumatism. His pulse was intermittent and arythmic and of low tension. The arteries were tortuous. There was no cardiac bruit, but the valve sounds were not sharp.

A diagnosis was made of neurasthenia and failing heart. Prolonged rest and retirement from active business advised.

Thirteen months later there were inco-ordination and weakness in legs, with some rigidity. There was lowering of the tactile sense in legs and ankles, but no anesthesia.

Eight months later there was marked lowering of tactile sensibility below the knees. Actual patches of anesthesia were present.

There was marked ataxia of gait and station, with loss of articular and posture sense in feet and toes, and eventual inability to walk alone.

Blood Examination.—A blood examination about this time revealed: Reds, 2,500,000; whites, 10,000; hgn., 55 per cent.; C. I., 1.1 per cent. A few days later the reds were 2,068,000; whites, 9,600; hgn., 54 per cent. Six nucleated reds in a leucocyte count of 500.

Remarks.—A diagnosis of probable pernicious anemia was made. The case terminated fatally about two years after the onset of the first symptoms.

Case 6.—For the notes of this case I am indebted to Dr A. L. Knight, the attending physician, who, although not consulted about the case until a few weeks before death, made a prompt and correct diagnosis.

Patient.—Mrs. F. S., widow, aged about 30, two children, had been in failing health for some months. There was no syphilis, but marked anemia with lemon yellow tint of skin. There was general weakness, but there were no mental defects and no sensory or reflex losses.

Blood Examination (Dr. W. E. Schenck): Reds, 1,509,320; whites, 4,200; hgn., 45 per cent.; color index, 1.5 per cent.

---

[1] See The Journal, March 2, 1901.

Differential Count: Adult whites, 64 per cent.; young, small, 17 per cent.; young, large, 14 per cent.; transitional, 1 per cent.; old eosinophiles, 1 per cent.; unknown, 3 per cent.; reds, normoblasts, 1,500; megaloblasts, 102; microblasts, 33; poikilocytosis present.

Case 7.—Mrs. A. S. H. was referred to me by Dr. W. M. Seamans of Delaware, Ohio. She was under my care at the Cincinnati Sanitarium from Nov. 1, 1904, to the date of her death, Dec. 28, 1904.

For some of the notes of case I am indebted to my associates, Dr. B. A. Williams and Dr. C. B. Rogers.

Complaint.—Diarrhea and nervousness of three months' duration.

Patient.—A married woman, aged 62, who has never been pregnant. Her father died of "heart disease." Her mother is living and in good health at over 80 years of age. Patient is the second of three children. There is no nervous disease in direct family.

Previous History.—Patient was under treatment at a private institution for "mental disease" ten years ago. Recovery was followed by "nervousness and irritability for years."

Examination.—Nov. 1, 1904: General development is fair, good complexion and teeth. Patient is somewhat emaciated. Mentally she is cheerful and bright, with good memory, and is hopeful. These conditions present day of examination were quite in contrast with her dispositon at other times, which is not at all amiable.

Heart and urine were negative. There was no cranial nerve palsy and no contraction of visual fields to rough test. Pupils responded promptly to light and accommodation tests.

Motion: She can walk with some assistance from others; gait is stiff; her fingers are stiff and movements slow in consequence.

Sensation: Pain sense is blunted or lost about wrists and ankles (*to a pin prick*). There is tactile anesthesia of feet and legs nearly to knees. *Heat and cold senses are delayed*, but usually correct.

Reflexes: Knee jerks are absent. Plantar reflexes flexor, but very slight.

Blood Counts (*Dr. W. E. Schenck*), Nov. 8, 1904: Reds, 2,248,000; whites, 1,500; hgn., 30 per cent.; color index, 0.70

Differential Count: Leucocytes, polymorphonuclears, 83 per cent.; young, small, 10; young, large, 6, 16 per cent.; eosinophiles, 1 per cent.; poikilocytosis, macrocytes and microcytes.

A diagnosis of secondary anemia was made.

Second Count, Nov. 21, 1904: Reds, 1,456,000; whites, 5,000; hgn., 30 per cent.; color index, 1.07; poikilocytosis.

Differential Count: Polymorphonuclears, 57 per cent.; small lymphocytes, 42 per cent.; large lymphocytes, 1 per cent.

A diagnosis of pernicious anemia *was made.*

Third Count, Dec. 6, 1904: Reds, 1,004,000; whites, 2,400; hgn., 30 per cent.; color index, 1.5.

Differential Count: Polymorphonuclears, 65.5 per cent.; young, small, 33.5; young, large, 15, 34 per cent.; eosinophiles, .5; poikilocytosis, chromatophilia, macrocytes, microcytes.

A diagnosis of pernicious anemia was made.

Fourth Count, Dec. 20, 1904: Reds, 1,268,000; whites, 3,600; hgn., 30 per cent.; color index, 1.2.

Differential Count: Polymorphonuclears, 62 per cent.; young, small, 36. young, large, 2, 38 per cent.; poikilocystosis, chromatophilia, macrocytes, microcytes.

A diagnosis of pernicious anemia was made.

Termination by exhaustion five months after onset of symptoms.

Case 8.—Mrs. A. P. C. was referred to me by Dr. Sutton of Aurora, Ind. The patient was under the care of myself and associates at the Cincinnati Sanitarium from Jan. 19, 1905, till her death, on Feb. 1, 1905.

Patient.—A woman, aged 48, the youngest of several children, married, one son, 16 years old, one miscarriage at 46 years, lues probable, complains that she "feels cold all the time," has pain in left hip.

History (from others).—The patient has been mentally "peculiar" for two years, "heard voices" once (auditory hallucinations). She has threatened suicide. She has loss of control of sphincters at times and there is general weakness.

Examination.—She is evidently extremely anemic and has lemon yellow skin. She is conscious only when aroused; does not speak, but nods head. Pulse, 130; respiration from 35 to 40; temperature, 100. There were no chest râles. Pupils were pin points; sphincters unreliable; knee jerks were absent; plantar reflexes, right flexor, left absent; there were no responses to pin pricks in lower extremities.

Blood Examination (Dr. W. E. Schenck), Jan. 24, 1905: Reds, 2,272,000; whites, 2,400; hgn., 38 per cent.; color index, 86; macrocytes and microcytes.

Differential Count: Polymorphonuclears, 71 per cent.; small lymphocytes, 23 per cent.; large lymphocytes, 3 per cent.; eosinophiles, 1 per cent.; myelocytes, 2 per cent.; total, 100 per cent.

A diagnosis of severe secondary anemia was made.

Second Blood Examination, Feb. 1, 1905: Reds, 2,412,000; whites, 4,200; hgn., 35 per cent.; color index, 0.73.

Differential Count: Polymorphonuclears, 76.5 per cent.; lymphocytes, small, 21, large, 2.5. Normoblast, one.

A diagnosis of secondary anemia *was made.*

Remarks.—While this case does not technically come within the limits of a "pernicious" type of anemia, as shown by the blood tests, yet there can be little doubt of the presence of a lethal blood state to which the fatal termination was due.

Case 9.—R. M. J., broker, single, was originally referred to me in June, 1898, by Dr. G. M. Allen, on account of a hemiplegia.

History.—My diagnosis at the time was of cerebral thrombosis of gummatous origin. Recovery was nearly complete, after some months, with only slight exaggeration of reflexes in the paralyzed side. I saw him subsequently at intervals of months, up to 1905. During this period he suffered from several attacks of aphasia and monoplegia, three or more convulsive attacks, all clearing up within a few hours or days, and leaving a slight but persistent mental weakening.

He still continued to do a certain amount of routine business, and his mental deterioration was not marked to a casual observer. In the early part of 1905 he passed from my observation, for several months, and I was informed that he was taking some form of mānual treatment.

After this he was bed-ridden and comatose much of the time, and came under the care of Dr. Joseph Eichberg, who has kindly favored me with the following notes of the case while under his treatment:

"Blood examination of Mr. J.: Reds, 800,000; whites, 6,400; hgn., 20 per cent.; color index, 1.25 per cent.

There was marked poikilocytosis. One large megaloblast was found in several fields. The patient died within three and one-half weeks of the time that I first saw him."

Remarks.—The long duration (seven years) of nervous symptoms of varied type preceding the development of anemia is notable—not, however, because of any likely connection of the two, since the history pointed rather distinctly to gummatous arteritis as the cause of the organic nervous state.

DISCUSSION.

Dr. David I. Wolfstein, Cincinnati, declared that this attempt to establish a prepernicious anemia is going too far and is bound to lead us into trouble, especially as pernicious anemia is a disease that is well known and in which the blood examination is very definite. One can hardly see how disturbances of sensation and inco-ordination can be considered prepernicious anemia. In his desire to establish a separate entity, Dr. Langdon has included cases that would be classed as cases of subacute degeneration of the cord, which we class as pernicious anemia. There ought to be very little difficulty in diagnosing this condition with the laboratory aids now at our disposal. Prepernicious anemia is almost a contradiction in terms. There are a great many nervous states, it is true, that might be produced by various forms of anemia, but Dr. Wolfstein has never seen anything except very severe secondary anemia, or a simple pernicious anemia, unless there was some condition in the blood findings that would account for it, that would produce so well-marked a clinical picture as Dr. Langdon presents.

spite of careful supporting treatment, and died in about three months.

The physician, under whose care she was, writes me that he concurred in the diagnosis of "combined sclerosis," and that the reflexes toward the end were "practically entirely lost."

While the diagnosis of pernicious anemia in this case may justly be open to criticism, owing to the absence of blood examination, yet the clinical features, evident anemia, the steady deterioration in strength and the fatal issue in a little more than two years, together with the absence of other disease of lethal nature, would all seem to render the presence of the morbid blood state extremely probable.

Case 2.—This case has already been reported in The Journal, March 2, 1901. A brief abstract is as follows:

History.—A. W. C., male, aged 34, American, married, no children, hospital supervisor and restaurant proprietor by occupation, was under observation from July, 1899, to the fatal termination of his illness in April, 1900. There was a history of three or four years' gradual failure of health, preceding actual illness.

Examination.—Syphilis was excluded. His habits were good. He complained of weakness and rigidity in legs, and was unable to walk without assistance from others.

Sensory and Motor Symptoms: There were defects of tactile and pain senses about ankles, and delay and hypesthesia in both, without actual anesthesia. There was motor weakness with rigidity of legs and inability to walk. There was also inco-ordination in the upper and lower extremities.

Reflexes: Knee jerks were plus. Ankle clonus was present on both sides. Plantar reflexes were of the distinct "Babinski" type.

There was no notable mental defect until twenty-four hours before death, when coma appeared.

Mucous stools were a marked symptom during the last few weeks. Also epistaxis.

Blood Counts, July 8, 1899 (Dr. M. A. Brown): Reds, 1,279,440; whites, 3,600; hgn., 32 1/6 per cent.; color index, 1.3; poikilocytosis, marked; nucleated reds numerous; megaloblasts more numerous than normoblasts.

Second Count, Feb. 13, 1902 (at pathologic laboratory, City Hospital): Reds, 1,661,805; whites, 3,000; hgn., 54 per cent.; color index, 1.54; eosinophiles, 9 per cent.; neutrophiles, 49 per cent.; small lymphocytes, 39 per cent.; large lymphocytes, 3 per cent.; piokilocytosis was not marked; megaloblasts, three seen.

Subsequent examination showed no material change.

Autopsy.—Autopsy and microscopic investigation by Dr. Wolfstein showed the typical cord lesion of Putnam-Dana type of combined sclerosis.[1]

Case 3.—J. W. D., man, aged 34, single, active business man, was seen Jan. 7, 1898, in consultation with Dr. G. W. Wire of Wilmington, Ohio.

History.—He has complained of "tired feeling" for past two months. He had a crop of "dry boils" from waist to knees, about three months previous to this examination. Family history is good. There is no syphilis. Anemia was evident. Bilateral hydrothorax was present. There was no ataxia or rigidity of limbs present and no defect of tactile or pain senses was noted.

Reflexes: Knee jerks were lively. Ankle clonus was absent. Plantar reflex was not noted.

Blood Count (Dr. W. E. Schenck): Reds, 1,200,000 (4 counts); whites, 4,000; hgn., 35 per cent.

Subsequent History.—I am indebted for the subsequent history of the case to Dr. Wire, who writes me that the patient did fairly well for five or six months, then rapidly weakened, but was not absolutely confined to his home until seventeen days before his death on Nov. 26, 1898.

Death was due to cerebral hemorrhage, preceded by retinal hemorrhages, which abolished vision.

Case 4.—C. H. L., aged 57, business man and capitalist, married, four children, was seen April 18, 1903, in consultation with Dr. J. H. Landis.

History.—Family history was good. His habits were good. There was no syphilis and no previous illness of consequence. He complained of peculiar feelings in hands ("as of corn-meal on them") and in feet (as if resting on a sponge). The duration of these symptoms was six months.

Examination.—He had a large frame, full habit; height, 6 feet; weight, 212 pounds. He was moderately anemic to the eye. Heart sounds were not sharp. There were no urinary symptoms. Pupils responded to light, but somewhat sluggishly.

Motor Apparatus: There was no palsy; no inco-ordination. Power was reduced in grasp, i. e., R. 66 kilos., L. 60 kilos (normal estimated at about 90).

Re-examination twelve days later showed R. 75k., L. 60k. by same dynamometer.

Sensation: There were no losses of tactile or pain senses and no obvious delay in transmission.

Reflexes: Knee jerks were good and equal.

Blood examination (Dr. W. E. Schenck): Reds, 3,016,000; whites, 6,400; hgn., 60 per cent.; color index, 1 per cent.; differential count; polymorphonuclears, 80 per cent.; young, 16 per cent.; eosinophiles, 4 per cent.; the reds were irregular in snape and size. Diagnosis was secondary anemia (erythrocytemia).

Subsequent History.—Patient was put on iron, arsenic and supporting treatment and sent to the seashore, where he appeared to improve for a time. Growing worse later, the blood was re-examined and a diagnosis of pernicious anemia was made.

Blood Examination, March 2, 1904 (Dr W. E. Schenck): Reds, 1,000,000; whites, 4,360; hgn., 25 per cent.; color index, 1.5 differential count, whites, polymorphonuclears, 81 per cent.; small lymphocytes, 16; large lymphocytes, 3; poikilocytosis, chromatophilia, microcytes and macrocytes.

Diagnosis: Pernicious anemia.

At this time Dr. Landis informs me there was spastic gait, plus knee jerks, and "Babinski" plantar reflexes; also some diarrhea of mucous type and loss of control of rectal sphincter with retained power over bladder. There were no mental defects. The fatal termination occurred about one year from the time of his first visit.

Case 5.—A. H., financier and man of affairs, aged 67, very active, married, with several children living and healthy, was seen in June, 1902, in consultation with Dr. H. K. Dunham.

History.—His only complaints were of numbness and coldness in fingers (both hands), and pain in right shoulder. He called it rheumatism. His pulse was intermittent and arythmic and of low tension. The arteries were tortuous. There was no cardiac bruit, but the valve sounds were not sharp.

A diagnosis was made of neurasthenia and failing heart. Prolonged rest and retirement from active business advised.

Thirteen months later there were inco-ordination and weakness in legs, with some rigidity. There was lowering of the tactile sense in legs and ankles, but no anesthesia.

Eight months later there was marked lowering of tactile sensibility below the knees. Actual patches of anesthesia were present.

There was marked ataxia of gait and station, with loss of articular and posture sense in feet and toes, and eventual inability to walk alone.

Blood Examination.—A blood examination about this time revealed: Reds, 2;500,000; whites, 10,000; hgn., 55 per cent.; C. I., 1.1 per cent. A few days later the reds were 2.068,000; whites, 9,600; hgn., 54 per cent. Six nucleated reds in a leucocyte count of 500.

Remarks.—A diagnosis of probable pernicious anemia was made. The case terminated fatally about two years after the onset of the first symptoms.

Case 6.—For the notes of this case I am indebted to Dr A. L. Knight, the attending physician, who, although not consulted about the case until a few weeks before death, made a prompt and correct diagnosis.

Patient.—Mrs. F. S., widow, aged about 30, two children, had been in failing health for some months. There was no syphilis, but marked anemia with lemon yellow tint of skin. There was general weakness, but there were no mental defects and no sensory or reflex losses.

Blood Examination (Dr. W. E. Schenck): Reds, 1,509.320; whites, 4,200; hgn., 45 per cent.; color index, 1.5 per cent.

---

[1] See The Journal, March 2, 1901.

Differential Count: Adult whites, 64 per cent.; young, small, 17 per cent.; young, large, 14 per cent.; transitional, 1 per cent.; old eosinophiles, 1 per cent.; unknown, 3 per cent.; reds, normoblasts, 1,500; megaloblasts, 102; microblasts, 33; poikilocytosis present.

Case 7.—Mrs. A. S. H. was referred to me by Dr. W. M. Seamans of Delaware, Ohio. She was under my care at the Cincinnati Sanitarium from Nov. 1, 1904, to the date of her death, Dec. 28, 1904.

For some of the notes of case I am indebted to my associates, Dr. B. A. Williams and Dr. C. B. Rogers.

Complaint.—Diarrhea and nervousness of three months' duration.

Patient.—A married woman, aged 62, who has never been pregnant. Her father died of "heart disease." Her mother is living and in good health at over 80 years of age. Patient is the second of three children. There is no nervous disease in direct family.

Previous History.—Patient was under treatment at a private institution for "mental disease" ten years ago. Recovery was followed by "nervousness and irritability for years."

Examination.—Nov. 1, 1904: General development is fair, good complexion and teeth. Patient is somewhat emaciated. Mentally she is cheerful and bright, with good memory, and is hopeful. These conditions present day of examination were quite in contrast with her dispositon at other times, which is not at all amiable.

Heart and urine were negative. There was no cranial nerve palsy and no contraction of visual fields to rough test. Pupils responded promptly to light and accommodation tests.

Motion: She can walk with some assistance from others; gait is stiff; her fingers are stiff and movements slow in consequence.

Sensation: Pain sense is blunted or lost about wrists and ankles (to a pin prick). There is tactile anesthesia of feet *and legs nearly to* knees. Heat and cold senses are delayed, but usually correct.

Reflexes: Knee jerks are absent. Plantar reflexes flexor, but very slight.

Blood Counts (Dr. W. E. Schenck), Nov. 8, 1904: Reds, 2,248,000; whites, 1,500; hgn., 30 per cent.; color index, 0.70

Differential Count: Leucocytes, polymorphonuclears, 83 per cent.; young, small, 10; young, large, 6, 16 per cent.; eosinophiles, 1 *per cent.; poikilocytosis,* macrocytes and microcytes.

A diagnosis of *secondary* anemia was made.

Second Count, Nov. 21, *1904: Reds, 1,456,000;* whites, 5.000; hgn., 30 *per cent.; color* index, 1.07; poikilocytosis.

Differential Count: Polymorphonuclears, 57 per cent.; small lymphocytes, 42 per cent.; large lymphocytes. 1 per cent.

A diagnosis *of* pernicious anemia was made.

Third Count, Dec. 6, 1904: Reds, 1,004,000; whites, 2,400; hgn., 30 per cent.; color index, 1.5.

Differential Count: Poly*morphonuclears, 65.5* per cent.; young, small, 33.5; young, large, 15, 34 per cent.; eosinophiles, .5: poikilocytosis, chromatophilia, *macrocytes*, microcytes.

A *diagnosis* of pernicious anemia *was made.*

Fourth Count, Dec. 20, 1904: Reds, 1,268,000; whites, 3,600: hgn., *30 per cent.*; color index, 1.2.

Differential *Count:* Polymorphonuclears, 62 per cent.; young, small, 36. *young, large, 2, 38 per cent.*; poikilocystosis, chromatophilia. macrocytes, microcytes.

A diagnosis of pernicious anemia was made.

Termination by exhaustion five months after *onset* of symptoms.

Case 8.—Mrs. A. P. C. was referred to me by Dr. Sutton of Aurora, Ind. The patient was under the care of myself and associates at the Cincinnati Sanitarium from Jan. 19, 1905, till her death, on Feb. 1, 1905.

Patient.—A woman, aged 48, the youngest of several children, married, one son, 16 years old, one miscarriage at 46 years, lues probable, complains that she "feels cold all the time," has pain in left hip.

History (from others).—*The* patient has been mentally "peculiar" for two years, "heard voices" once (auditory hallucinations). She has threatened suicide. She has loss of control of sphincters at times and there is general weakness.

Examination.—She is evidently extremely anemic and has lemon yellow skin. She is conscious only when aroused; does not speak, but nods head. Pulse, 130; respiration from 35 to 40; temperature, 100. There were no chest râles. Pupils were pin points; sphincters unreliable; knee jerks were absent; plantar reflexes, right flexor, left absent; there were no responses to pin pricks in lower extremities.

Blood Examination (Dr. W. E. Schenck), Jan. 24, 1905: Reds, 2,272,000; whites, 2,400; hgn., 38 per cent.; color index, 86; macrocytes and microcytes.

Differential Count: Polymorphonuclears, 71 per cent.; small lymphocytes, 23 per cent.; large lymphocytes, 3 per cent.; eosinophiles, 1 per cent.; myelocytes, 2 per cent.; total, 100 per cent.

A diagnosis of severe secondary anemia was made.

Second Blood Examination, Feb. 1, 1905: Reds, 2,412,000; whites, 4,200; hgn., 35 per cent.; color index, 0.73.

Differential Count: Polymorphonuclears, 76.5 per cent.; lymphocytes, small, 21, large, 2.5. Normoblast, *one.*

A diagnosis of secondary anemia was made.

Remarks.—While this case does not technically come within the limits of a "pernicious" type of anemia, as shown by the blood tests, yet there can be little doubt of the presence of a lethal blood state to which the fatal termination was due.

Case 9.—R. M. J., broker, single, was originally referred to me in June, 1898, by Dr. G. M. Allen, *on account* of a hemiplegia.

History.—My diagnosis at the *time* was *of cerebral thrombosis* of gummatous origin. Recovery was nearly complete, after some months, with only slight exaggeration of reflexes in the paralyzed side. I saw him subsequently at intervals of months, up to 1905. During this period he suffered from several attacks of aphasia and monoplegia, three *or more* convulsive attacks, all clearing up within a few hours or days, and leaving a slight but persistent *mental weakening.*

He still continued to do a certain amount of routine business, and his mental deterioration was *not* marked to a casual observer. In the early part of 1905 he passed from my observation, for several months, and I was informed that he was taking some form of mânual treatment.

After this he was bed-ridden and comatose much of the time, and came under the care of Dr. Joseph Eichberg, *who* has kindly favored me with the following notes of the case while under his treatment:

"Blood examination of Mr. J.: Reds, 800,000; whites, 6,400; hgn., 20 per cent.; color index, 1.25 per *cent.*

There was marked poikilocytosis. One large megaloblast was found in several fields. The patient died within three and one-half weeks of the time that I first saw him."

Remarks.—The long duration (seven years) of nervous symptoms of varied type preceding the development of anemia is notable—not, however, because of any likely connection of the two, since the history pointed rather distinctly to gummatous arteritis as the cause of the organic nervous state.

DISCUSSION.

Dr. David I. Wolfstein, Cincinnati, declared that this attempt to establish a prepernicious anemia is *going too far and* is bound to lead us into trouble, especially as pernicious anemia is a disease that is well known and in which the blood examination is very *definite. One* can hardly *see how* disturbances of sensation and inco-ordination can be considered prepernicious anemia. In his *desire to establish* a separate entity, Dr. Langdon has included cases that would be classed as cases of subacute degeneration of the cord, which we class as pernicious anemia. There ought to be very little difficulty *in* diagnosing this *condition* with the laboratory aids now at our disposal. Prepernicious anemia is almost a contradiction in terms. There are a great many *nervous* states, it is true, that might be *produced* by various forms of anemia, but Dr. Wolfstein has never seen anything except very *severe* secondary anemia, or a simple pernicious *anemia*, unless there was some condition in the *blood* findings that would account for it, that would produce so well-marked a clinical picture as Dr. Langdon presents.

Dr. H. A. Tomlinson, St. Peter, Minn., said that behind the anemia there is the instability of the individual. In these cases we are probably dealing with a secondary anemia, having its origin in chronic autointoxication; in other words, an intoxication anemia. A careful study of these cases clinically will show that behind the autointoxication there is faulty elimination. After correction of the faulty elimination, and under improved nutrition, the anemia disappears. In the majority of cases of chronic nephritis, in which there is marked sensory and often motor disturbance, there is secondary anemia, and all the manifestations described by Dr. Langdon. Dr. Tomlinson agreed with Dr. Wolfstein that there is no ground for grouping these manifestations into a special classification, because they may result from a number of disease conditions. We have no right to ascribe to the anemia the power to cause the nervous disturbance.

THE TUBERCULOSIS PROBLEM IN LOS ANGELES.*

GEORGE H. KRESS, M.D.
LOS ANGELES, CAL.

The mortality statistics for pulmonary tuberculosis for the city of Los Angeles, when analyzed, suggest some rather interesting questions, not only for the physicians and citizens of Los Angeles, but for our professional brethren east of the Rocky Mountains, since it is these latter gentlemen who are largely responsible for the fact that Los Angeles has a tuberculosis problem. It is the purpose of this paper to consider various phases of these statistics, to draw some conclusions therefrom and to suggest some measures whereby such danger as exists for the public health from an unusually high mortality rate from pulmonary tuberculosis may be minimized or entirely prevented.

In order that the task may be accomplished with some degree of completeness, most of the etiologic factors that are known to influence the morbidity and mortality rates of the great white plague will be considered in turn.

FACTORS INFLUENCING MORBIDITY AND MORTALITY RATES.

Climate.—We who live in this country and know its many advantages, need not be told that the pure air coming from ocean and desert, the good soil drainage, the great amount of sunshine, the temperature which, while pleasant and equable, varies sufficiently during the day and night to be anything but enervating, are atmospheric and topographical conditions not favorable to either the development or the spread of consumption under ordinary conditions.

So far as the value of our climate may be called into question as regards the treatment of tuberculosis, we have but to remember that, in a general way, there is no such thing as a specific climate for the cure of tuberculosis; that it is the manner, rather than the place of, treatment that is of first importance; that the disease has been cured, in fact, in climates of widely different characteristics, and that the Southern California climate, in allowing an out-of-door life the year round, in a pure atmosphere, with an abundance of sunshine, possesses advantages excelled by but few localities. So that what may be said later concerning a large mortality rate from tuberculosis in Los Angeles exists not because of, but rather in spite of, a climate, which with proper cases, under suitable conditions, would and does exercise a potent influence in the cure of many, many patients.

Sociologic and Industrial Conditions.—Our northern friends and some few others at various times, in prognosticating the industrial growth of our prosperous city, have been in the habit of saying, "Los Angeles has nothing and exists on nothing else than its climate and its tourists." Taken literally, such an assertion is, of course, a great exaggeration, but there is this kernel of truth within it, that Los Angeles has, for a city of its size, not nearly the number of manufacturing interests that are found in many eastern municipalities of the same population.

With this apology for the use of dry figures, the ordinary causal factors of consumption will be considered in turn.

STATISTICS.

The statistics here given have been taken largely from the last United States Census reports and from the death certificates on file in the City Health Office. While allowance must be made for slight errors, since all the items on the death certificates are not invariably filled in by physicians, they are, in the main, correct. The registration area of the United States contains about 40 per cent. of the population of the country, and, as it has much more accurate methods of keeping vital statistics, its figures are, therefore, taken in preference to those for the United States as a whole.

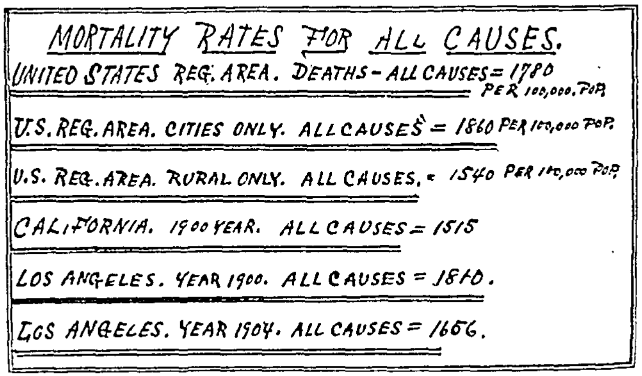

Diagram 1.—Showing the mortality rates, from all causes, for the United States and Los Angeles. It will be seen that in spite of having the second highest tuberculosis mortality rate in the United States, the mortality rate for Los Angeles, from all causes, is below that of the average registration cities of the United States.

The following figures show the annual economic loss to the United States from preventable deaths from pulmonary tuberculosis: Annual total number of deaths in the United States from consumption, 150,000; in California, over 4,000; in Los Angeles, over 600. Average age of patient at time of death, 35 years. From one-third to one-half of all deaths between the ages of 15 and 35 are due to tuberculosis.

Average years of after-life expected by man of 35, about 32 years; cost of rearing child to age of 20, at $100 a year for 25,000 persons, $50,000,000; same for 60,000 other persons who die between ages of 20 and 35, $90,000,000; diminished earning power of $150 each for 200,000 sick consumptives, $30,000,000; loss of future savings at $1,000 each of those who die between the ages of 20 and 60, $130,000,000; annual expense of sickness of 150,000 persons, at $50 each, $7,500,000; extra expense of caring for families of 75,000 married consumptives at $25, $1,875,000; grand total in monetary loss to the United States, $309,875,000 annually.

No estimate in dollars and cents is placed on the mental and physical suffering of the patients or their families.

---

* Read before the Los Angeles County Medical Association June 2, 1905.

These estimates, if anything, err on the side of conservatism. Counting the cost of rearing a child, the loss in diminished wage earnings during sickness, the loss through premature death, the expense of sickness and expense of caring for dependents of deceased consumptives, there is a loss to the United States, on a conservative basis, of more than 300 millions of dollars annually.

All this loss annually from a preventable disease!

The accompanying charts, diagrams and tables have been made to bring out more clearly such etiologic factors as have a bearing on the subject under discussion.

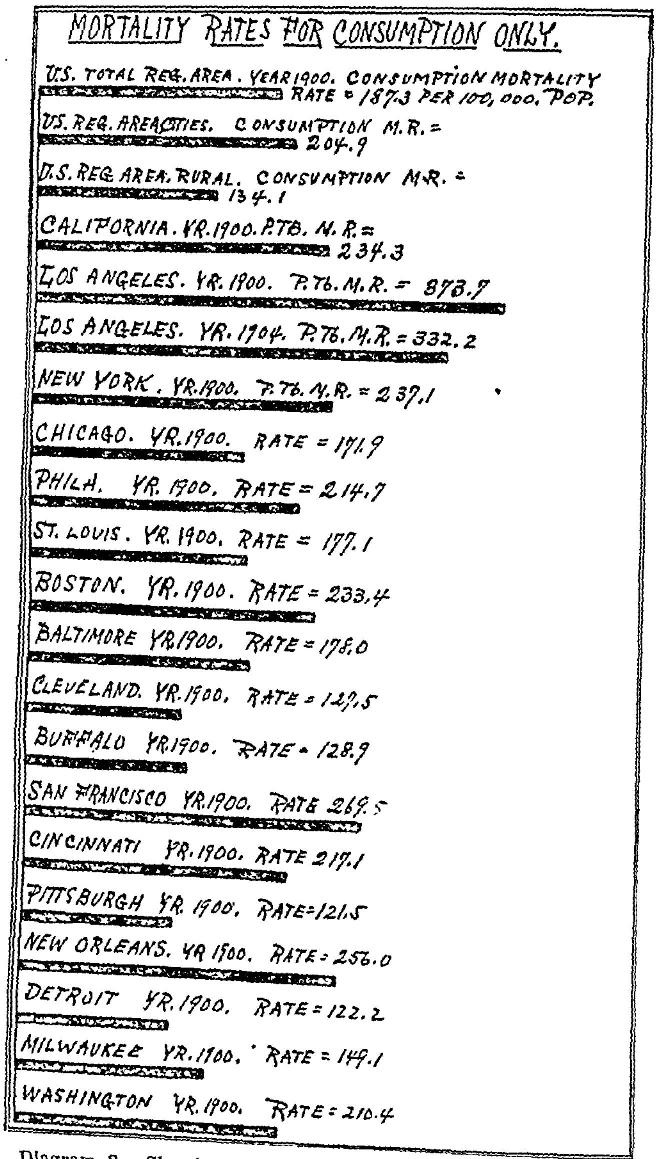

Diagram 2.—Showing the mortality rates for consumption only (a larger unit of measurement being here used than in the preceding table, to bring out the differences more clearly). The first horizontal black line shows the average of the registration area of the United States. The Los Angeles line, the longest given, is almost twice as great as that for the United States registration area average. Below the Los Angeles lines are given in order the tuberculosis mortality rates and lines for the fifteen largest cities in the country. The Los Angeles rate is larger than that of any of these large cities, where local conditions would lead one to expect high death rates from consumption.

CONCLUSIONS TO BE DRAWN FROM THESE STATISTICS.

To summarize, it is noted that Los Angeles has a climate and topographical environment which, under proper hygienic and sanitary living, is inimical to the development of pulmonary tuberculosis among its inhabitants. The general industrial, sanitary and sociologic conditions of the city are likewise unfavorable to the spread of the disease. Yet, in spite of this, Los Angeles, in the census year 1900, had the second highest mortality rate from pulmonary tuberculosis in the United States.

If the rate has diminished somewhat during the last five years, it may be said with equal truth that the mortality rates of other cities have likewise diminished, especially in the large cities where the campaign for better housing and sanitation for the poor has been vigorously carried on. New York, with its new tenement house laws and park systems, is a case in point.

The consideration of the tuberculosis mortality rate of Los Angeles in relation to such factors as race, sex, age, conjugal condition, season of the year, and so on, brought out no particularly unusual points, other than that the ordinary variations of the United States registration area were somewhat intensified. Most of the variations could be traced to that one feature which is especially responsible for our high death rate, viz., the fact that southern California is known to possess a climate favorable to the cure of tuberculosis, as a result of which knowledge people flock to this region from all parts of the country, too often, however, in such advanced stages of the disease that recovery is quite out of the question. Consequently, the Los Angeles death rate from tuberculosis assumes most undue proportions.

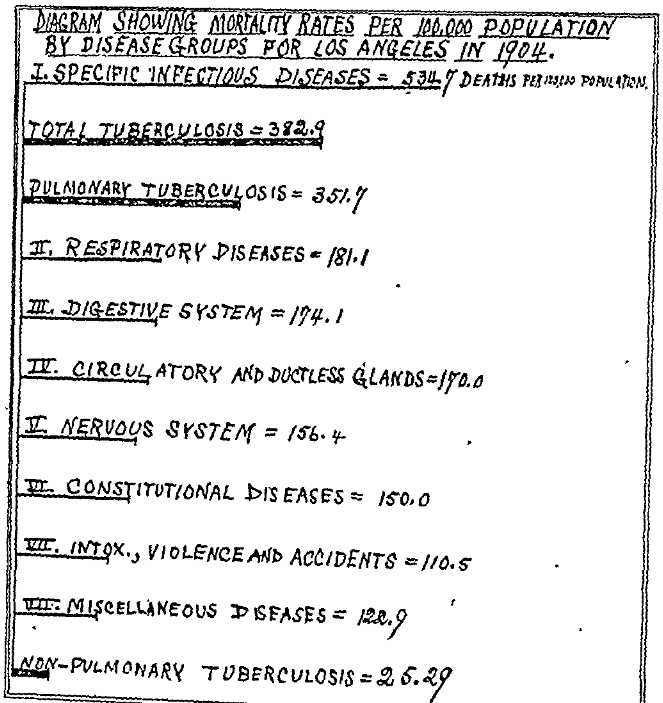

Diagram 3.—Showing the mortality rates, for Los Angeles, of diseases by the health office groups, except that the tuberculosis mortality is added for sake of contrast. The large portion of the line for specific infectious diseases which the tuberculosis line would cover and the much greater mortality from this single disease than for the entire groups of diseases, are both worthy of notice.

There are naturally more deaths among the males, because a larger number of that sex can come here unattended. The large number of deaths among adults is likewise due to the same reason. As yet the comparatively few deaths which occur among the native population of Los Angeles from consumption take place, many of them among the Mexicans and others who live in the poorest circumstances under the worst hygienic conditions.

The table showing the term of residence prior to death is one of the most significant given. From it is noted beyond any question of argument that from one-third to one-half of those who die of consumption in this city, and who came here in the hope of regaining health and strength, are hopelessly diseased with tuberculosis. For such persons, many of whom die within a few months after their arrival in southern California, death at home, with the tender ministrations of relatives and friends, would be preferable to the hopeless outlook presented here. Forced by the lack of material means to seek lodging in the cheapest rooming houses, unable to purchase nourishing food, without which even the best climate on earth is of but little avail; forced, when their material means are not so limited to conceal the nature of their malady from the keeper of the rooming house, lest they be requested to go elsewhere for lodging; eating in the public restaurants, among the better class of which even, the cleansing of dishes is not any too well performed, and where among the cheapest this work is decidedly neglected, the lot of these hopelessly advanced victims of consumption is, indeed, hard. Their sufferings terminate somewhat when, bedridden, they are admitted to the County Hospital, where, even though the white-capped nurses be strangers, they may spend a few hours of peace before death.

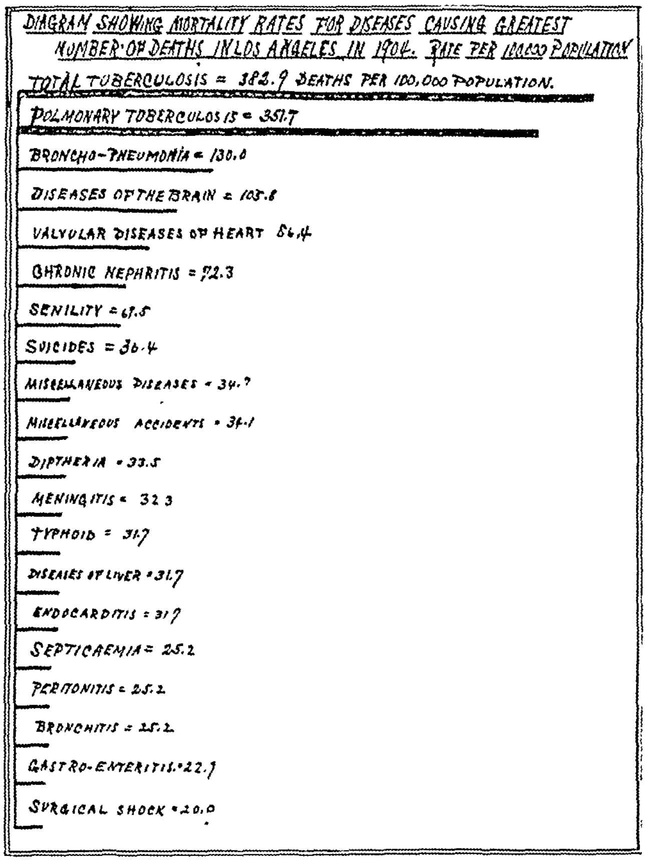

Diagram 4.—Showing how the Los Angeles death rate from consumption outclasses the other main causes of death in that city.

The following is the tuberculosis mortality on different Los Angeles streets: Hope, 10; Fourth, Hill and Pico, 9 each; Main, 8; First and Twenty-second, 7 each; Alameda, Seventh and Twenty-sixth, 6 each; Aliso, Fifth, Figueroa, Los Angeles, St. Julian and Twelfth, 5 each; Avenue Sixth, 4; Boyle, Castelar, Eighth, Grand, Girard, Maple, Soto, Spring, Third, Twenty-first, Twenty-eighth, Vermont and Wall, 4 each; Avenue Five, 4; Buena Vista, Central, Elizabeth, Fifteenth, Flower, Marchessault, Pasadena, Ruth, San Fernando, Santa Fe, Sickle, Sixth, Temple, Tennessee, Twenty-third and Twenty-fifth, 3 each, and so on; County Hospital, 118; coroner, 34.

One hundred and eighteen deaths from consumption in the Los Angeles County Hospital last year! Thirty-four deaths in rooms and lodging houses, without a physician in attendance, so that a coroner's inquest was necessary! The Associated Charities yearly provide transportation to an additional hundred or so of consumptive persons to enable them to return to their homes because they are unable to keep up the struggle here.

If so many patients die as charity patients in our public hospital, can there be any doubt but that, prior to their admission to that charity institution, they must have lived in the cheapest of lodging or rooming houses? Would it not be a safe assumption to state that 25 per cent. of the mortality from this dread disease—which is responsible for more than one-fifth of the entire mortality of this city—and about 50 per cent. of the morbidity from consumption is to be found in the lodging and rooming houses of Los Angeles; in brief, that 25 per cent. of the deaths and 50 per cent. of the tuberculosis morbidity (whatever this latter figure may be; under our present laws we have no means of finding this out) is to be found in those dwellings which harbor about only 30 per cent. of our population? More than that, owing on the one hand to the prejudice among proprietors of good dwelling houses to accept such persons as tenants or lodgers, and, on the other, to the poverty-stricken condition of a large number of these patients, it is reasonable to assume that the proportion of consumptives to the poorer lodging houses is much larger than this. If this be true, it means that in the places where the largest number of poverty-stricken, poorly nourished and depressed men are to be found; in the buildings where the amount of cubic air space is least; where ventilation is prevented to keep up body heat and to avoid draughts; in the dwellings where the bed clothing is filthiest, where bath tubs and lavatories are the fewest and then of the crudest pattern; in short, where bad hygiene, worse sanitation, and the largest number of predisposed persons are congregated in the smallest space (precisely those conditions most potent in the spread of this disease), we find the largest number of consumptives, and not only that, but the largest number of consumptives in advanced stages of the dis-

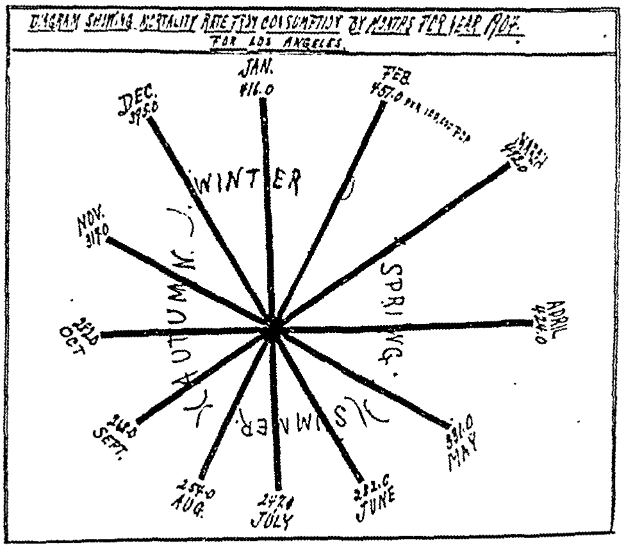

Diagram 5.—Presenting the mortality rates by months, as given in Table 6, in the form of a diagram.

ease, that stage in which millions of bacilli are cast off by each patient in his sputum of a single day.

On what premises and by what process of reasoning are we warranted in concluding that, under such lodging-house conditions, tuberculosis does not endanger the public health of our city? When a firebrand is thrown into an inflammable structure, the result that is expected is a conflagration. When foci of infection are scattered in places where predisposed persons can most easily acquire the disease, one expects new cases of the disease to arise. The spread of the disease may be confined for a time to such places, but it does not take long before some of these diseased persons repay their debt to a criminally neglected community by infecting inhabitants in better portions of the city.

By what right does any municipality endanger the County Medical Association, which is a component unit of the Americal Medical Association, and which is supposed to take an active participation in all efforts to promote the public health, excuse itself for its dereliction of duty?

Is it right that we as physicians should allow this work to be done almost entirely by a half-dozen men, the members of the Board of Health, and more especially by our health officer? Our politicians will not undertake this work, because it conflicts with vested interests that at once make themselves heard when reform is attempted; but let other vested interests, viz., those representing the great mass of our citizens, who stand for decent sanitation and hygiene, be heard with equal force, and our politicians will not turn an unwilling ear.

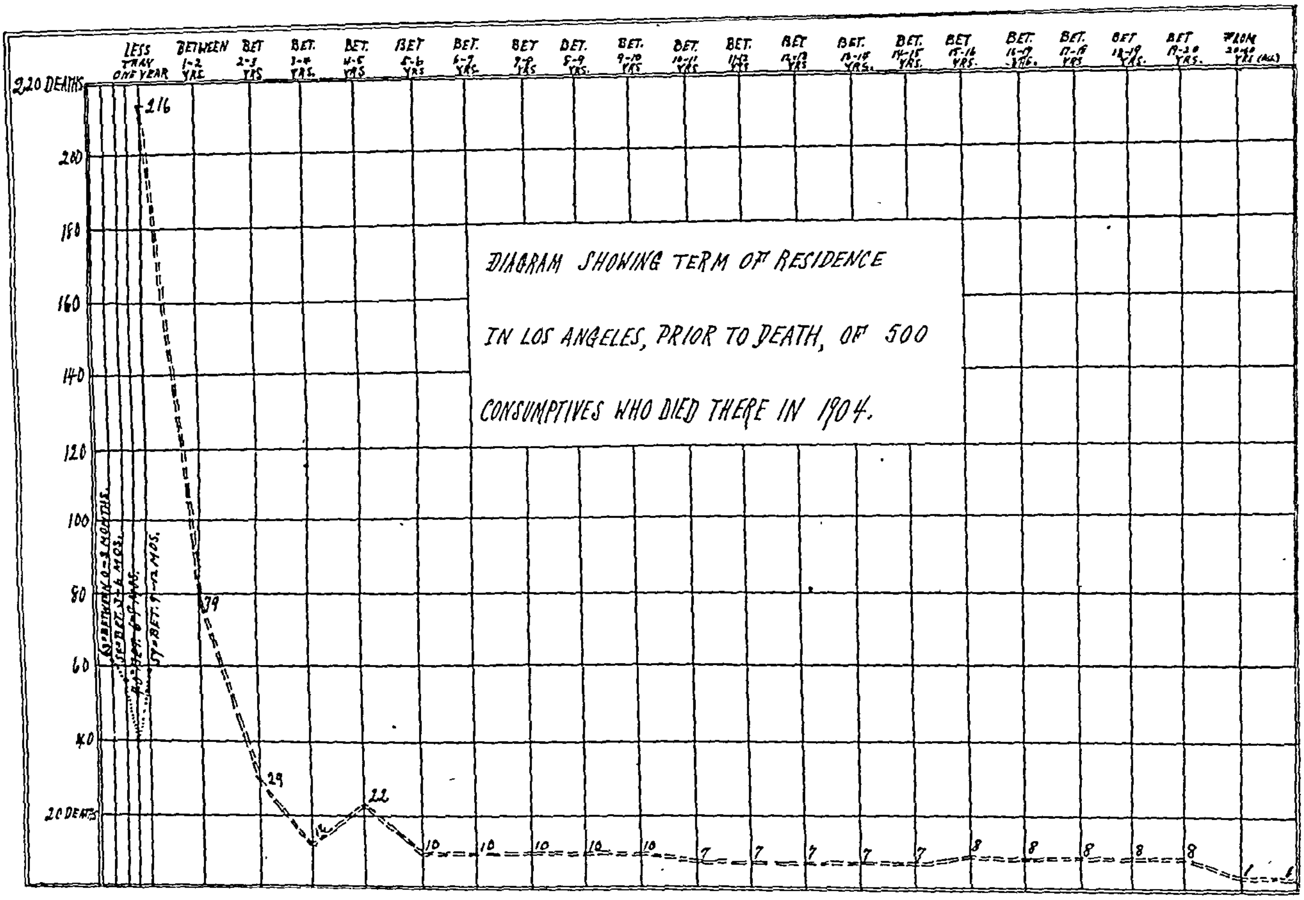

Diagram 6.—This diagram shows the length of residence in Los Angeles prior to death of 500 consumptives who died here in 1904. The high proportion of deaths for the four seasons of the first year is worthy of notice, also the height of the curve for the first year. It then drops rapidly, until about the fifth year, when it runs along at a very low figure. This means two things: One, that a large proportion of patients come here in hopelessly advanced stages of the disease; and two, that after two or three years' residence, the other patients have a fairly good chance for lengthened years of life.

life of its healthy inhabitants, especially when this danger to others comes from the violation of the most fundamental laws of decent and hygienic living? What does Los Angeles intend to do in this matter? Shall it close its eyes and allow the next census to publish the same unfavorable mortality rate from consumption? How long will it be, whether justly or unjustly, before it becomes noised abroad throughout the country that our tuberculosis mortality is so excessive as to be a danger to healthy persons?

Los Angeles can account for her tuberculosis death rate without shame to herself. The fault lies much more at the door of those eastern physicians who send hopelessly advanced patients to this community than at the doors of the local physicians. In what manner do we as physicians, and how does this Los Angeles

THE SOLUTION OF THE LOS ANGELES TUBERCULOSIS PROBLEM.

The solution of the tuberculosis problem in Los Angeles, while not a complicated one, has ramifications in many directions. It may be worth while to consider the more important of these in some detail.

Compulsory Notification.—Under the present health rules and regulations, our health officer has but little control over the tuberculosis situation, because he is denied the power to execute. This is so serious a problem that the health officer of this community should not only have mortality statistics bearing on tuberculosis, but also should know how much morbidity there is from that disease, and in what parts of the city it is located, so that intelligent action may be taken.

In New York City every physician is obliged to report every case of tuberculosis with which he comes in contact. This information is sent to the health department on a blank devised for that purpose, in which the physician not only gives the name and address of the patient, but states his opinion of the hygienic condition of the patient's surroundings. The patient is supplied with literature informing him how to avoid reinfection of himself (a most important point, in that it leads the patient to observe safeguards for others as well), and how to avoid infecting others, a precaution he is sometimes loth to take until the danger to self is first emphasized. This notification information is for the use of the health department only, i. e., the book is open to the inspection of health department officials only. When charity patients are reported, or when the attending physician states that hygienic conditions are bad, a physician or deputy from the health department investigates and gives needed information and assistance for the betterment of the conditions. From time to time inspections are made to see if these measures are complied with. When these measures are ignorantly or willfully but persistently neglected, the health officer has the power to transfer such a patient from his unhygienic surroundings to the tuberculosis hospital on North Brothers Island.

Los Angeles needs just such a law, only, unfortunately, the health officer in this state has no authority forcibly to send a patient to a hospital.

MORTALITY TABLES BY RACE

RACE	UNITED STATES					LOS ANGELES				
	POPULATION U.S REG. AREA	DEATHS. ALL CAUSES		DEATHS. CONSUMPTION		POPULATION LOS ANGELES (ESTIMATED)	DEATHS. ALL CAUSES		DEATHS CONSUMPTION	
		NUMBER	RATE	NUMBER	RATE		NUMBER	RATE	NUMBER	RATE
WHITE	28,555,810	475,640	1,729.0	47,041.	174.0	196,184	2,847	1,450	578	297.0
TOTAL COLORED	1,251,467	31,125	2,927.0	6,063.	487.0	8,784	134	1,520	40	457.0
NEGRO						4,000	88	2,200	26.	650.0
CHINESE						3,500	46	1,150	10	400.0
JAPANESE									4	216.0

Table 1.—This table shows how much higher is the death rate for the colored races than for the white. The negroes, Chinese and Japanese of Los Angeles have not quite so high a death rate from this disease as their colored brethren of the United States, as a whole.

As is known, tuberculosis has been listed by our local board of health among notifiable diseases. How this voluntary notification has worked out in practice is seen from the health officer's last annual report, where, with 651 deaths from tuberculosis, only 206 cases of tuberculosis were reported, and, although the health department makes free sputum examinations, only 434 specimens were sent in, and of these only 167 specimens gave positive results.

Knowing the opposition of patients and their families to having their cases reported, is it any wonder that physicians avoid much trouble by not reporting them? The solution of this phase of the question lies not in voluntary, but in compulsory notification, and that, as stated, can best be followed out after the Biggs plan of New York, the information being for the health department's use only, no placard being placed on the house; the sole purpose of the arrangement being to protect the patient and his fellow-men, but at the same time to inconvenience both as little as possible.

Such a law Los Angeles should have. Such a law Los Angeles some day will have. Just how long the wait is to be will depend, in good part, on the attitude the medical men of the community take on this question. It is to be hoped that those who would be tempted to oppose compulsory notification will accept the change of heart of New York medical men who at first opposed the Biggs system, as an indication of how experience would cause them to change their own opinion. Compulsory notification of cases would also perform this further excellent service to the anti-tuberculosis cause, in that it would overcome the prejudice of the laity to tuberculosis as a cause of death, so that the true number of those who die from this disease could be more accurately determined. At present, large allowances must be made for error in mortality statistics in this disease. Ultimately also, by necessitating a recorded diagnosis during life, it would be a valuable influence in leading medical men to make earlier diagnoses, i. e., diagnoses in the curable stages.

Compulsory Fumigation.—The health officer of Los Angeles, when a death certificate comes in marked pulmonary tuberculosis, sends out a deputy to fumigate the premises where the individual died, but the fumigator can do nothing, if the owner or lessee of the building forbids him to enter. This deputy has told me of the different ways in which he is met by the families or friends of the deceased, and has stated that in a number of cases he is denied admission. Los Angeles needs a statute that will make it compulsory to have rooms fumigated after the removal or death of a consumptive patient. The work should be carried on, of course, with as much privacy as possible. The benefit of fumigation would not be helped by undue publicity of the work, with its subsequent gossip of neighbors and the corresponding distress of the family.

MORTALITY RATES BY NATIONS. MORTALITY NUMBERS BY STATES

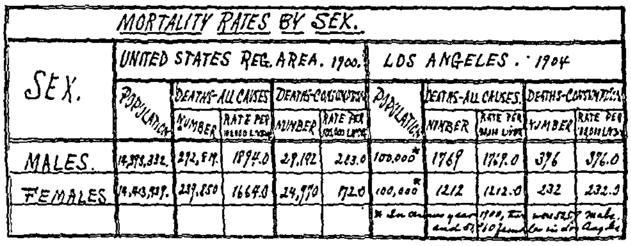
NATIONALITY	MORTALITY RATES PER 100,000 POP. U.S. REG. AREA.	MORTALITY RATES PER 100,000 POP LOS ANGELES.	WHERE NATIVE AMERICANS AMONG DECEASED CONSUMPTIVES CAME FROM. LOS ANGELES	
TOTAL COLORED	589.4	457.0	LOS ANGELES = 13	
IRISH	428.0	240.0	CALIFORNIA = 59	
BOHEMIANS	235.2	—	ILLINOIS = 45	
SCANDINAVIANS	233.7	390.0	NEW YORK = 27	
FRENCH	220.6	160.0	MISSOURI = 27	
GERMANY	205.9	230.0	OHIO = 25	
CANADA	199.7	370.0	PENNSYLVANIA = 24	
UNITED STATES	162.5	270.0	INDIANA = 19	
ENGLAND	151.4	202.0	MICHIGAN = 15	
ITALIANS	149.9	80.0	IOWA = 15	
RUSSIANS	131.1	650.0	TEXAS = 12	
MEXICANS		770.0	TENNESSEE = 11	
CHINESE		400.0	KENTUCKY = 11	
JAPANESE		266.0	MASSACHUSETTS = 11	

Table 2.—This gives in the three left-hand columns the mortality rates by nations, for the United States as a whole and for Los Angeles alone. In the United States registration area the Irish, next to the colored persons, have the highest death rate from consumption. In the column for Los Angeles the mortality rate of the Mexicans is especially worthy of notice. A considerable proportion of the native-born population of Los Angeles who die of pulmonary tuberculosis are of Mexican parentage. In the two right-hand columns may be seen from what states the native-born Americans who died here last year from consumption, came. Los Angeles had only thirteen deaths among her native born, and the Californians in all numbered only 59. Illinois sent us 45 consumptives, New York 27, Missouri 27, Ohio 25, and so on.

A statute should also be passed to prevent the furnishings of the room from being sold to second-hand dealers until after they had been fumigated.

Ordinances to Place Lodging House Licenses on the Same Basis as Dairy Licenses.—In his last annual report the health officer of Los Angeles stated: "We recommend that an ordinance be passed requiring all proprietors of lodging houses to secure a permit to conduct a rooming house, and that any proprietor who fails to furnish clean bed clothing, etc., be refused a permit, and in case he fails to keep or to maintain a clean and sanitary place his permit be suspended." What action has been taken in this matter? The health officer is the executive officer of the Board of Health. Is it right to thrust on him in addition the legislative functions? Is it not the duty of physicians, yes, of a committee of the Los Angeles County Medical Association, to take this matter in hand and make this suggestion of the health officer a reality? Such an ordinance should have provisions as to the amount of air space to each occupant of a room; should provide for an adequate amount of ventilation; should insist on clean bed clothing and furniture; should demand accessible bath and wash rooms and lavatories. Proprietors of places violating the requirements, and who, on notice to clean up, fail to do so, should be punished by withdrawal of license, just as a milk license is withdrawn from a dairyman for an analogous offense.

What objection can there be to such a law? If it be inconsistent for a physician or for a body of physicians to oppose fundamental provisions of cleanliness and sanitation, is it not equally inconsistent, in view of the high nature of their calling and better knowledge of these subjects, for them to make no effort to bring about the adoption of necessary hygienic and sanitary measures?



MORTALITY RATES BY SEX.

SEX.	UNITED STATES REG. AREA. 1900.					LOS ANGELES. 1904				
	POPULATION	DEATHS-ALL CAUSES		DEATHS-CONSUMPTION		POPULATION	DEATHS-ALL CAUSES.		DEATHS-CONSUMPTION

MALES.	14,393,332.	272,617.	1894.0	29,192	203.0	100,000*	1769	1769.0	376	376.0
FEMALES	14,413,939.	239,850	1664.0	24,770	172.0	100,000*	1212	1212.0	232	232.0
						* In [illegible]	year [illegible] and [illegible]	1900, [illegible] 10 [illegible]	[illegible]	male, [illegible]

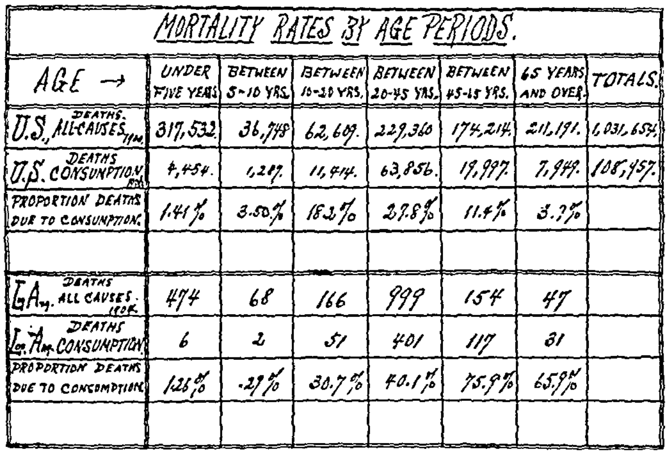
Table 3.—This table shows that while for the United States registration area the deaths among males are to the consumptive deaths among females, as 8 to 7; for Los Angeles this ratio is about 15 males to 9 females.

Building Regulations.—We can all become indignant over the cheapest lodging houses, forgetting that, because of this very cheapness, they offer a roof to sleep under and a space to lie on for those unfortunate members of our community who have no means to turn to something better. Some of these shacks have existed for years.

To extirpate an established evil is always difficult. What is being done to prevent the erection of like places? The new building ordinance (No. 10,415, New Series) went into effect on Dec. 31, 1904, and its forty-two articles extend over more than three and one-half full pages of the *Los Angeles Times* of Jan. 9, 1905. Therein are specifications as to material and mode of construction for private and public buildings of all conceivable descriptions; fire-escape and plumbing requirements are all pointed out, but nowhere is mention made of the amount of air space per occupant nor the amount of ventilation required.

The new building ordinance deals almost entirely with material specifications. This is in keeping with this very material age. We do not know who composed the committee that drew up the specifications, but it would seem that that committee should have had among its members at least one medical man who had given thought to building and other requirements. Such a medical man might have come to the aid of the building inspector when he sought to have a rule passed whereby the number of buildings of frame construction would be limited for certain size lots. Under the present ordinance, a single frame building may not contain more than a stipulated number of rooms or apartments. Nothing is said about the size of the lot. Hungry land and property owners violate the spirit of the ordinance by erecting buildings, each with the maximum number of rooms, a foot or so apart from one another, just enough space to enable them to state that the buildings are separate. The narrow areas between them are excellent flues, and the buildings make splendid fire traps. Where was our medical society when these laws were being adopted? It was conspicuous by its absence, as has been said, or it might have been of aid to our building inspector in having his much-needed regulations adopted.

Building requirements on the subject of air space per occupant, ventilation, lavatory arrangements, plumbing and the like need not necessarily stop with our cheaper lodging houses. Without entering into a discussion as to the probable effect on future generations, of our present-day flat life, we may well ask ourselves what kind of physical beings these compartment buildings in time will produce, and whether children born and reared in such structures, where the ingenuity of man is bent on seeing how he can transform the dwelling house of a generation ago into one or two small rooms, and these, in turn, perhaps into living closets no larger than those used by our grandmothers in storing clothes, will be of a high physical standard? In any case the duty of the present generation is to demand that an adequate supply of oxygen and sunlight be allowed to reach the interior of all classes of dwellings. The thickly carpeted, stuffy, ill-ventilated apartment house or hotel can at times be as much of a disease breeder as the poor hovel or miserable tenement, where such of our fellows as have fallen behind in the life race are of necessity forced to make their homes. If the principle of good ventilation be applicable for the tenement, it should be made applicable to the apartment house and hotel also.

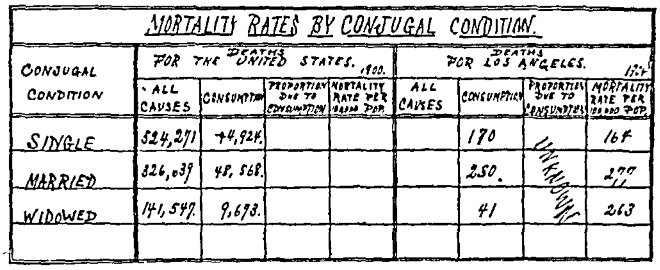


MORTALITY RATES BY AGE PERIODS.

AGE →	UNDER FIVE YEARS	BETWEEN 5-10 YRS.	BETWEEN 10-20 YRS.	BETWEEN 20-45 YRS.	BETWEEN 45-65 YRS.	65 YEARS AND OVER.	TOTALS.
U.S., DEATHS. ALL-CAUSES, 1900.	317,532.	36,748	62,609.	229,360	174,214.	211,191.	1,031,654.
U.S. DEATHS CONSUMPTION 1900.	4,454.	1,287.	11,414.	63,856.	19,997.	7,949.	108,457.
PROPORTION DEATHS DUE TO CONSUMPTION.	1.41%	3.50%	18.2%	27.8%	11.4%	3.7%	
L.A., DEATHS ALL CAUSES. 1904.	474	68	166	999	154	47	
Los Ang. DEATHS CONSUMPTION	6	2	51	401	117	31	
PROPORTION DEATHS DUE TO CONSUMPTION.	1.26%	.29%	30.7%	40.1%	75.9%	65.9%	

Table 4.—This shows the tuberculosis mortality rate for the United States and Los Angeles by age periods. The proportion of deaths for the adult age periods is much greater for Los Angeles than for the United States.

A Municipal Dispensary for Consumptives.—Los Angeles can not avoid the conclusion that a large number of penniless consumptives take up their residence within its boundaries. Some of these patients come here on the advice of eastern physicians. Happily, the general awakening that has come about through the active antituberculosis warfare of late years has resulted in attention being directed to the evil advice of sending advanced patients far from home; with the establishment of sanatoria in the Eastern States and the wider acceptation of the knowledge that tuberculosis in the early stages is curable in any climate, there will be fewer and fewer of such offenses traceable to our brother physicians in the states east of the Rockies. There will always be a goodly number of consumptives who will come here on their own responsibility. The potent influence exerted by a good climate in the process of cure can not be denied and the victims of consumption will ever seek it. Many come in early stages, but, lacking means, hurt themselves by overwork. Improving their condition and arresting the disease, they imagine themselves entirely well and overdo. As their illness continues and draws on their available funds, they seek cheaper and cheaper lodging and eating houses. The larger proportion who go to the County Hospital to die has already been noted.



MORTALITY RATES BY CONJUGAL CONDITION.

CONJUGAL CONDITION	FOR THE UNITED STATES. 1900. DEATHS ALL CAUSES	CONSUMPTION	PROPORTION DUE TO CONSUMPTION	MORTALITY RATE PER 100,000 POP.	FOR LOS ANGELES. 1904. DEATHS ALL CAUSES	CONSUMPTION	PROPORTION DUE TO CONSUMPTION	MORTALITY RATE PER 100,000 POP.
SINGLE	524,271	44,924.				170	UNKNOWN	164
MARRIED	326,039	48,568.				250.		277
WIDOWED	141,547.	9,673.				41		263

Table 5.—This shows the relation to conjugal condition.

To these poverty-stricken consumptives, citizens of eastern municipalities, rather than those of Los Angeles, the city of the Los Angelenos owes an obligation. First to them as individuals, because to those who are ill unto death and without means it is under obligation to provide advice and aid. They should not be made to shift for themselves. Almost any afternoon, at the office of the Associated Charities in the county courthouse, inquiries are made by one or more of these unfortunates, who, without home or shelter, realize at last that they are ill, indeed, and seek medical advice or transportation back to their old home. Why not put this work on a separate basis; establish a room somewhere, with a dispensary staff, where this class of consumptives can be reached and put on the road to recovery, or, at least, if that be impossible, be so guarded that their presence in this community shall not be a source of danger to healthy citizens.

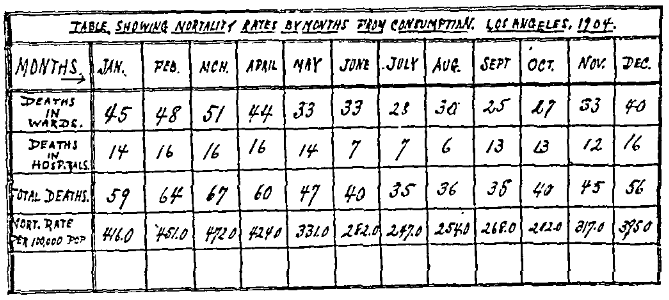


TABLE SHOWING MORTALITY RATES BY MONTHS FROM CONSUMPTION. LOS ANGELES, 1904.

MONTHS →	JAN.	FEB.	MCH.	APRIL	MAY	JUNE	JULY	AUG.	SEPT	OCT.	NOV.	DEC.
DEATHS IN WARDS.	45	48	51	44	33	33	28	30	25	27	33	40
DEATHS IN HOSPITALS.	14	16	16	16	14	7	7	6	13	13	12	16
TOTAL DEATHS.	59	64	67	60	47	40	35	36	38	40	45	56
MORT. RATE PER 100,000 POP	446.0	451.0	472.0	424.0	331.0	282.0	247.0	254.0	268.0	282.0	317.0	375.0

Table 6.—This shows how the number of deaths from consumption varies during the different months of the year.

Antispitting Ordinance.—There can be no doubt about the millions of bacilli that are expectorated by a single consumptive in the course of twenty-four hours. Fortunately, where this is expectorated on streets in the summear season, when the sunshine is at its height, it is soon rendered inocceuous. Not so, however, with the sputum in insanitary lodging houses. No matter what may be the most frequent channels of infection, whether by the respiratory or by the alimentary tract, it is generally conceded that infection from bovine sources is comparatively infrequent, if it exists at all, and that, as a rule, all individuals acquire their disease from other persons. The most frequent medium of transmission is the sputum. Antispitting ordinances are good. Too much publicity can not be given to this danger. Let the ordinance be enforced. More than that, the lodging houses should be made to have signs in prominent places, forbidding expectoration, except in suitable spittoons.

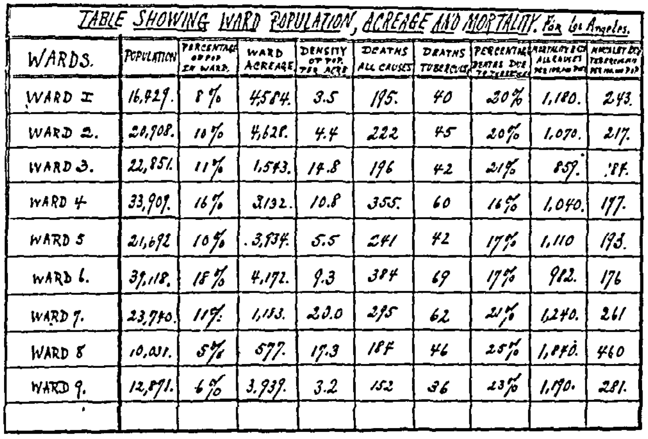

TABLE SHOWING WARD POPULATION, ACREAGE AND MORTALITY. For Los Angeles.

WARDS.	POPULATION	PERCENTAGE OF POP. IN WARD.	WARD ACREAGE	DENSITY OF POP. PER ACRE	DEATHS ALL CAUSES	DEATHS TUBERCULOSIS	PERCENTAGE DEATHS DUE TO TUBERCULOSIS	MORTALITY RATE ALL CAUSES PER 100,000 POP	MORTALITY RATE TUBERCULOSIS PER 100,000 POP
WARD I	16,429.	8%	4,584.	3.5	195.	40	20%	1,180.	243.
WARD 2.	20,908.	10%	4,628.	4.4	222	45	20%	1,070.	217.
WARD 3.	22,851.	11%	1,543.	14.8	196	42	21%	859.	188.
WARD 4	33,909.	16%	3,132.	10.8	355.	60	16%	1,040.	177.
WARD 5	21,692	10%	3,934.	5.5	241	42	17%	1,110	193.
WARD 6.	39,118.	18%	4,172.	9.3	384	69	17%	982.	176
WARD 7.	23,740.	11%	1,153.	20.0	295	62	21%	1,240.	261
WARD 8	10,031.	5%	577.	17.3	184	46	25%	1,840.	460
WARD 9.	12,871.	6%	3,939.	3.2	152	36	23%	1,170.	281.

Table 7.—This shows the relation of tuberculosis mortality by wards, to ward population, acreage, density, deaths from all causes, and so on. The crowded Eighth Ward, i. e., the plaza district, excels in both its death rates from all causes and from tuberculosis, that of any other ward. While ward density is greater for Ward 7 by acreage, the dwelling places of Ward 8 are much more densely populated.

If sputum is dangerous on the sidewalk, it is equally and more dangerous in the public buildings, in elevators, in cabs, in streets, in steam railways, in hotels, and in lodging and dwelling houses.

Disinfection of Pullman Cars.—The problem of making the owners of those temporary and traveling lodging houses known as Pullman sleepers fumigate the berths and furnishings is an intricate and difficult one. If the municipality can not solve it, the legislature should be requested to give the State Board of Health adequate powers in this connection.

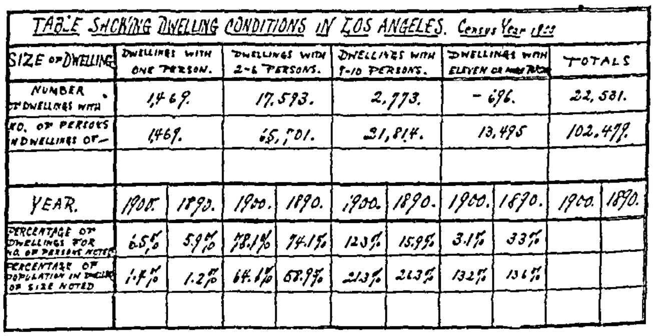

TABLE SHOWING DWELLING CONDITIONS IN LOS ANGELES. Census Year 1900

SIZE OF DWELLING	DWELLINGS WITH ONE PERSON.		DWELLINGS WITH 2-6 PERSONS.		DWELLINGS WITH 7-10 PERSONS.		DWELLINGS WITH ELEVEN OR MORE PERSONS		TOTALS	
NUMBER OF DWELLINGS WITH	1,469.		17,593.		2,773.		- 696.		22,581.	
NO. OF PERSONS IN DWELLINGS OF—	1469.		65,701.		21,814.		13,495		102,479.	
YEAR.	1900.	1890.	1900.	1890.	1900.	1890.	1900.	1890.	1900.	1890.
PERCENTAGE OF DWELLINGS FOR NO. OF PERSONS NOTED	6.5%	5.9%	78.1%	74.1%	12.3%	15.9%	3.1%	3.3%		
PERCENTAGE OF POPULATION IN DWELLINGS OF SIZE NOTED	1.4%	1.2%	64.1%	68.9%	21.3%	21.3%	13.2%	13.6%		

Table 8.—This gives some figures from the latest United States Census reports, showing how large a proportion of the population of Los Angeles lives in simple dwellings and in boarding houses.

Municipal Sanatoria and Hospitals for Consumptives.—New York and Cincinnati have established municipal sanatoria for consumptives. These perform a most excellent work not only through the direct cures, but also in being centers from which a better and wider knowledge concerning the best methods of prophylaxis and cure permeate the masses. Unfortunately, the poor can not easily be taught to regard these institutions in their proper light. In Los Angeles, by the action of the city council, consumptives can go only to the County Hospital, if we except the endowed Barlow Sanatorium, with its as yet limited number of beds. The council made no effort to abate the dangers in lodging houses, but for the private hospitals, where sputa could be disinfected, stringent rules were laid down. The theory is good, but the council, in its wisdom, if it would have been consistent, should have first turned its attention to the worst offenders, viz., the cheaper lodging houses.

The Los Angeles County Hospital has several wards for bedridden consumptives and a few tents for ambulant cases. As soon as patients get in fair condition, in other words, as soon as the active stage for which they were admitted abates, they are urged to seek quarters elsewhere. The County Hospital does this in sheer self-defense. Its entire equipment could be given over to this disease. It is true that many of these patients should have been treated by other municipalities, but since they are here they must be treated humanely.

With this mild climate, why would it not be a wise and economical thing to model after the plan adopted by Texas? That state found that its prisons had an unusually high mortality from tuberculosis. Dr. Fowler, the prison physician, sought permission to take such consumptive prisoners to the Wynne State Farm, an abandoned state prison farm with buildings. These buildings were turned into a sanatorium, hospital, farm and prison, all in one. The prisoners were treated according to the extent of the disease. Light farming, dairy work and poultry raising were done by those who were able to work. The farm produce more than paid the cost of maintenance of the institution, if the expense of guarding the prisoners be deducted. The lives of many of these men were prolonged or saved, and many other prisoners who would have been their companions in the closed prisons escaped infection; escaped, in fact, a form of murder not within the pale of the law.

With the climate of California, which is equally as beneficent as that of Texas, why could not Los Angeles pursue a similar plan? With no expense for guarding, why could not such an institution, a municipal sanatorium, be made self-sustaining here? A dairy herd, a poultry ranch and a truck garden, all requiring but comparatively light work, could be instituted, and, with proper management, could be put on as self-supporting a basis as the Texas farm. With pure air, nourishing food and good medical supervision, we have the essence, the triad of present-day methods in the treatment of this disease. With these, then, the amount of good which could be done can hardly be estimated. The air costs nothing, the food could be furnished by the labor of the patients, and the other expenses of the institution need not be much.

IN CONCLUSION.

If Los Angeles would prevent the large number of tuberculous sick, who are domiciled within its boundaries, from being a danger to their fellow-citizens, it behooves her to consider some such measures as have been outlined above.

If the physicians of Los Angeles would remain true to the tenets of their profession, it becomes their duty to take a hand in the solution of this problem.

If the Los Angeles County Medical Association, a basic unit of the American Medical Association, would remain true to its own obligations, and true to its major or parent organizations—the American Medical Association and the Medical Society of the State of California—it will aspire to give something more to its members than a didactic or even a clinical course of medicine or surgery, by taking a hand and doing its share in the solution of the many hygienic problems which confront this rapidly growing municipality.

One of these problems is the tuberculosis situation. It has as yet reached no undue danger. It should not be allowed to do so. To call attention to the need of its investigation has been one of the objects of this paper.

THE TRANSPLANTATION OF ORGANS.

A PRELIMINARY COMMUNICATION.[*]

ALEXIS CARREL, M.D.
CHICAGO.

This operation consists of extirpating an organ, with its vessels, of putting it in another region, and of uniting its vessels to a neighboring artery and vein. If the organ is replaced in the same animal from which it was removed, the operation is called an autotransplantation. If it is placed in another animal of the same species it is called a homotransplantation, while if it is placed in an animal of a different species, the operation is called a heterotransplantation.

The so-defined transplantation completely differs from the well-known experiments of subcutaneous or intraperitoneal grafts of small slices of organs.

LITERATURE.

The literature of the transplantation of organs is not extensive.

In 1901-02 I began experimenting with the view of finding a method of substituting a sound organ for a diseased one, e. g., of treating Bright's disease by replacing the diseased kidney by a normal one, or myxedema by transplanting a sound thyroid gland and securing it a blood supply by arterial and venous anastomosis. These first experiments were made in the Faculty of Medicine of the University of Lyons.

The transplantation of the thyroid gland, with its vessels, was performed on a large dog.[1] The right thyroid gland was dissected and its vessels cut. The largest artery and vein were united by a termino-lateral anastomosis to the carotid artery, and the external jugular vein. The circulation was re-established. It was impossible to observe physiologic results, owing to coagulation, which soon occurred, due to the bad aseptic and technical conditions of the operation.

About the same time the transplantation of the kidney was made.[2] The carotid and the jugular of a dog were dissected and prepared for anastomosis. The kidney, having been extirpated, with its vessels and its ureter, was put into the cervical wound. End-to-end anastomoses of the renal artery to the carotid, and of the renal vein to the jugular, were performed. The end of the ureter was united to a small opening of the skin, located a little above the sternum. On release of the clamps, the circulation was immediately re-established, and seemed thoroughly normal. After a few hours a clear fluid began flowing from the ureter. Permanent results were not observed, on account of septic complications.

In the same year, and prior to this, similar experiments, of which I was then ignorant, were performed by Ullmann.[3] His method was different. He used Payr's tubes for uniting the blood vessels. Definitive results were not observed. In 1903 the same experiment was made by Carl Beck of Chicago, but not published.

In 1905 Floresco[4] continued these experiments. He succeeded in transplanting the kidney into the lumbar region. The urine escaped into the bladder. My technic of anastomosing blood vessels was used with a slight modification. The operation was successful, but the anatomic and physiologic results have not yet been published.

In 1905 several series of experiments were performed by Dr. Guthrie and myself in the physiologic and surgical rooms of the Hull laboratory, in order to study the results of the transplantation of the blood vessels[5] of the heart, of the thigh, of the kidney and of the other glands.[6] I am very glad of this occasion to thank Dr. Stewart for giving me the privilege of performing these researches in his laboratory.

PROBLEMS CONNECTED WITH VISCERAL TRANSPLANTATION.

It is impossible to discuss here all the problems which the question of transplantation of organs raises. We will only consider the most important conditions which are necessary to the nutrition of the transplanted organs.

In case of autotransplantation or homotransplantation, the establishment of a good circulation through the anastomoses ordinarily renders the operation successful. The life of the transplanted organs depends almost entirely on the circulation. If the vessels become obliterated, gangrene destroys the organ. Obliteration can occur very easily. It may be produced by a great many causes; for instance, injury of the endothelium by the forceps, the needles or the clamps of the temporary hemostasis, clots on the perforating stitches, fall of the external sheath in the opening of the vessel, and, above all, lack of perfect asepsis.

The ordinary surgical methods of blood-vessel anastomosis have failed to give successful results in the transplantation of organs. At first I used tubes of magnesium or tubes of "caramel," but without good results. Coagulation occurred. Afterward I found a method of suturing which was often successful. By degrees that method has been improved in such a manner that now obliteration almost never occurs. Dr. Guthrie and I, operating together, obtain practically constantly good results. That very important question of technic being settled, autotransplantation and homotransplantation become almost easy.

The problem of the heterotransplantation is much more complicated. It is well known that the serum of an animal in many cases is toxic for the cells of an animal of another species. The aim of these researches being to determine the possibility of transplanting organs from animal to man, that question is very important. Fortunately, biologic laws are not without exceptions. Perhaps the human serum is not toxic for the cells of some animals. We have some reason to think that organs of the anthropoid apes transplanted on man may not be injured by the serum, for the blood of ape and man are inactive toward each other. Besides, it might be possible to use anticytolytic serums. All these points are unknown and must be experimentally studied.

POSSIBLE RESULTS OF VISCERAL TRANSPLANTATION.

Only a few of the possible results of the transplantation of organs will be mentioned in this paper. We do not want to discuss here the physiologic applications of the method. They are numerous and of considerable importance. Already we have performed several experiments along this line. For instance, Dr. Stewart and I have transplanted the kidney, with reversal of the circulation, in order to study the modifications of the secretion. With Dr. Guthrie, I transplanted one of the kidneys of a dog into the cervical region, and, on the third day after the operation, made a comparative study of the urine secreted by the transplanted and the sound kidney.[7] I performed also the transplantation of the heart of a dog on the carotid and the jugular of another dog. The heart was beating and the blood circulating through it. Dr. Guthrie and I established an arterial circulation through the right inferior thyroid vein of a dog, which had symmetrical hypertrophy of the thyroid glands. Marked changes occurred. Thus it appears that the reversal of the circulation in only one vein of a gland may alter the physiologic processes. The replantation of the thyroid gland was successfully made.[8] Probably our knowledge of the pancreas, the spleen, etc., may be increased by this method.

From a clinical standpoint, the transplantation of organs may become important. Perhaps it will be possible to treat myxedema, idiocy, etc., by transplanting a sound thyroid gland with anastomosis of the thyroid vessels to suitable arteries and veins. In kidney affections the transplantation of a sound kidney may be of benefit. Perhaps, after a complete amputation of arm, leg, or thigh, it may be possible to replant the limb, or another similar limb, if it is procurable.

A great many experiments on animals must be performed before using that method on man. As yet it is impossible to say whether or not the transplantation of organs will yield practical results. It seems possible, and we hope that it may open new fields in therapy and biology.

I wish to thank Dr. Guthrie for helping me in the revision of this paper.

Consultation.—If the physician is worried and anxious about his case and desires advice from a man who has had more experience in that particular disease, it seems only proper that his brother practitioner should come to his aid as a consultant for a small fee, or for no fee, if none is obtainable from the patient. It is the bond of professional brotherhood that seeks to lessen the mental stress in both instances. Yet consultants have been known, I understand, to refuse thus to relieve the anxiety of a doctor, because the payment by the patient of a certain fee was not possible. There is little doubt that the family physician at times pays consultation fees out of his own pocket in order to do his best for patients with whose straitened circumstances he is familiar.—John B. Roberts.

TRANSPERITONEAL LIGATION OF THE RENAL VESSELS

AS A PRELIMINARY TO A LUMBAR NEPHRECTOMY IN TUBERCULOSIS OR MALIGNANT GROWTHS OF THE KIDNEY.

GEORGE WALKER, M.D.
Associate in Surgery, Johns Hopkins University.
BALTIMORE.

A recent somewhat exhaustive study of tuberculosis of the kidney, the results of which have been published elsewhere, necessitated the examination of a large number of pathologic specimens, not only of renal tuberculosis but also of malignant tumors, in the Johns Hopkins Pathological Laboratory. From a careful analysis of over 400 cases of renal tuberculosis which I have collected from the literature and from personal observations on a number of instances of tuberculosis and malignant growth, I have been led to conclude that in the course of a lumbar nephrectomy for either of these two conditions, the operator is liable to squeeze tuberculous or malignant material into the general circulation and thereby cause an infection or metastasis. This conclusion is based on the following facts:

First.—Microscopic examination of numerous specimens of renal tuberculosis showed that the lymphatic vessels and the capillaries not infrequently end very near the tuberculous area. A certain number of these vessels are blocked by a proliferation of the endothelial cells, but in others the lumen is distinctly patent, so that it is possible in the course of certain manipulations that some of the tuberculous material may be squeezed into them, and thus gain entrance into the blood or lymph circulation. Closely similar physical conditions are seen in malignant growths.

Second.—In certain types of malignant tumors of the kidney the disease process extends well into the renal vein, sometimes forming a definite projection without having become an intimate part of the vessel wall. In all such cases it is very obvious that a small particle might very readily become detached and pass into the vein.

Third.—In two cases which came under my notice an acute, more or less general, tuberculosis followed the removal of the tuberculous kidney, and produced death within two months. In several instances belonging to my series of collected cases similar results were noted. Thus on one of my patients, who suffered from a renal and secondary bladder tuberculosis, a nephrectomy was done. A temperature of 102 degrees F. developed on the second day and the fever continued to the end. For the first ten days no focus could be found, but later trouble was discovered in the lower part of the right lung. This spread, the disease became general, and the patient died from miliary tuberculosis at the end of two and a half months.

Fourth.—In doing a lumbar nephrectomy, in order to free the kidney from its bed, it is necessary to press, squeeze and otherwise manipulate the organ rather roughly.

In view of the above facts, it has occurred to me that it is very possible, and indeed probable, that, during such manipulations as are required in the performance of nephrectomy, tuberculous material carrying tubercle bacilli in cases of renal tuberculosis or malignant material from a malignant growth can very readily be squeezed into the lymphatic or blood circulation, and thus give rise to a general infection.

In order to prevent such a possibility, I propose the following operation:

Do a laparotomy, push the intestines to one side, incise the posterior peritoneum, expose the renal vessels, put a double ligature around each of them, cut between and free the distal end for a short distance. In passing the ligatures it is well to include a certain amount of the immediately surrounding tissue, so as to pass around and ligate the lymph tract, which is not visible but which runs alongside of and very near to either the artery or vein. The peritoneum is then closed posteriorly and the anterior abdominal wound sutured in the usual manner. The patient is then turned on his side and the ordinary lumbar nephrectomy is done.

It may be asked why, when the abdomen is open, we should not remove the kidney through this wound. As a contraindication is the fact that with the very best operators the mortality for a transperitoneal nephrectomy is by 3 per cent. higher than for a lumbar nephrectomy.

It may be objected that this procedure produces two separate wounds and prolongs the time of operation. This is, to a certain extent, true, but it must be remembered that after the vessels have been ligated and cut, and to a certain extent freed, the time and manipulations necessary for a lumbar nephrectomy are reduced by fully one-half, so that the time spent in the preliminary ligation is offset by the lessening of the work required for the lumbar procedure.

The opening of the peritoneum under proper precautions should not in any sense add to the mortality of the operation.

The above procedure I simply propose for consideration. I have not done it, nor have I seen it done, but I suggest the method on theoretical grounds. The point which I wish to emphasize is that the usual method of doing a nephrectomy, in that it necessitates a squeezing of the kidney while the vessels are still open, is certainly dangerous in cases of tuberculosis or malignant growth.

Special Articles

MEDICAL AFFAIRS IN THE HEART OF THE ARCTICS.

N. SENN, M.D.
Professor of Surgery, The University of Chicago: Professor of Surgery and Head of the Surgical Department Rush Medical College.
CHICAGO.

(Concluded from page 1569.)

Epistaxis.—During the summer the Eskimos become so plethoric that Nature seeks to give relief by draining away the superfluous blood by hemorrhages from the nose. Epistaxis is a very common complaint in summer. I have frequently observed it, especially in young men who rowed my boat or accompanied me on my hunting trips inland. Any unusual exertion brought on the attacks. Men were more frequently subject to such attacks than women, and, although I could not get any definite information, I surmise that in women Nature relieves the abnormal congestion by increasing the menstrual flow.

Degeneration Diseases.—The Eskimos in the Arctic region are singularly free from the long list of degenerative diseases which cause so much suffering and cut short the lives of so many victims in civilized life. Commander Peary assured me that he had never seen a case of dropsy or apoplexy among his numerous Eskimo acquaintances. The only Eskimo in whom I detected arterial degeneration was the syphilitic to whom I have referred before. I examined the radial pulse of several men who were at least 70 years old, and found it as soft and as regular as that of a healthy young adult. None of these showed even a trace of orcus senilis. Bright's disease, cirrhosis of the liver, diabetes, arteriosclerosis, coxitis senilis, cataract and other diseases resulting from visceral degeneration evidently do not occur in the Arctic region.

Ship Catarrh.—When the natives came on board the *Erik* and *Roosevelt,* with the exception of a few from the North Star Bay settlement who brought with them a slight nasal catarrh, they were free from catarrhal affection of the respiratory organs. In a day or two most of them were afflicted with a severe cough and a thin mucous discharge from the nose—in other words, an acute catarrhal affection of the nose and large bronchial tubes. This is a familiar disease to seamen who visit this region. The natives expect it when they board a vessel. The pure sterile air of the Arctic region does not contain the essential microbic cause of catarrhal inflammation. The ship brings the microbes and the coal-dust inhaled prepares the soil for their specific pathogenic action. This nasal and bronchial catarrh of the natives contracted so promptly on board ship is familiarly known as "ship catarrh." It lasts only a few days and does not appear to give rise to any considerable constitutional disturbance, as all those afflicted went about, ate their rations with a ravenous appetite, and the men lent valuable assistance in loading and unloading the cargo of both ships.

Epidemic Diseases.—Some ten years ago Commander Peary made a careful count of the Eskimos of that part of the west coast of Greenland north of the Danish colonies and settlements and fixed their number at 243. Since that time the population has diminished and at present does not exceed 150, and of these the women outnumber the men by far. Since that time the population has been decimated by two epidemics, Arctic dysentery and la grippe.

Arctic Dysentery.—During the years 1901-1902, 35 Eskimos were taken ill with fever and dysenteric discharges. During the beginning of the epidemic, which originated at Cape York, it was believed that the patients were made ill by ptomain poisoning, but the spread of the disease after change of diet soon furnished proof of the true nature of the disease. The disease pursued a very severe course and four of the Eskimos died. In the severest cases delirium was a prominent clinical feature. The tenesmus and bloody mucus pointed to the large intestine as the seat of the disease. The patients who survived became emaciated to a skeleton and did not recover their former strength for several months. It was ascertained later that the disease had its origin in Finland, traveled across Siberia, made its appearance at Cape Barrow, Alaska, finally cropped out in this remote part of the world and from here took its flight as far as Ungava Bay, an arm of Hudson Strait, where it proved very fatal to the Eskimos of that locality. The Greenland Eskimos abandoned the place when the disease had expended its force and that was the end of the epidemic. This disease traveled an enormous distance, from Finland to Ungava Bay, and crossed vast stretches of uninhabited territory, and from country to country between which there was no communication by human beings, and the only conclusion we can come to regarding its occurrence in so many isolated places in the Arctic region is that the parasitic cause was carried by animals, undoubtedly migratory birds. Most of the water fowl in the Arctics are infested with parasites, and the most common vermin, which the Eskimos carry in their clothing and relish as a delicacy eaten raw and squirming, is a large louse which selects for its host the most numerous of all Arctic birds—the little auk. There is every reason to believe that birds can become the carriers of pathogenic germs and can convey them from place to place, either in their feathers or in discharges from the intestinal canal.

La grippe, in its endless clinical forms, had its origin in the cradle of the North, and has since spread from there nearly over the entire surface of the inhabited parts of the world. It seems to have no respect for climate and nationality. This disease reached the Eskimos in the north of Greenland during the winter of 1896-1897. It attacked young and old alike, but proved more fatal in adults than in children. The southern settlements suffered more than the northern, but its spread from one settlement to another was very rapid. The bacillus of la grippe in this epidemic selected the nasal passages, the pharynx and large bronchial tubes as favorite seats for localization. The exact mortality is not known, but a number of the most useful men in the different settlements succumbed to it. From eye witnesses I ascertained that in nearly all cases nasal obstruction was one of the most distressing symptoms and that in blowing the nose something like membrane was expelled. Some believed that the epidemic was diphtheria, but the disease proved much less severe in the case of children than in adults and in none of them did it extend to the larynx. Aching pains in the back and limbs and great depression, mental and physical, were invariably complained of by patients old enough to express their feelings. The disease has not reappeared since.

Female Predominance.—The predominance of the female over the male population, the large number of children and young widows without mates remind us of another fruitful cause of the falling off of the Eskimo population—it is the risk to life of the walrus hunter. The male walrus, and the mother walrus as long as her child needs protection, are fighters. Commander Peary says that the walrus when in a fighting mood is a more dangerous enemy than the polar bear. Walrus hunting calls for skill and strength, and among the Eskimos this work falls to the lot of the younger men. The kayak, by means of which the hunting is done, is a very frail craft. The Eskimos can not swim, hence if the walrus, with its powerful tusks, tears a big hole in the sealskin of the kayak or careens the little craft, with few exceptions it comes out victorious from the fight, and the poor hunter drowns or is killed by the infuriated foe. Few years pass without one or more lives being lost in this manner. As all property is held in common, the loss of an able-bodied man to a settlement means a great calamity, as his widow, children and other relatives whom he may have to support all become a charge on the community.

A People Without a Physician.—Nearly all primitive races feel the needs of some one specially qualified to dress wounds, mend broken bones, and to whom they can apply for aid when disease throws the shadows of death over them. This sense of helplessness in case of accident or disease is inborn, as well as the desire for medical aid when needed. The Polynesians have their "Kahunas," the Indians their "medicine men," but the Eskimos, perhaps because so few accidents occur among them and because their climate and manner of living exempt them from so many diseases which support physicians in civilized communities, have felt no such need of medical aid. They have neither physicians nor medicines. Here is a part of the world in which disease, when it occurs, is allowed to take its own course. Even Nature has ignored medicine in the Arctics. About the only vegetable product I could find here that could make any claim to the possession of medicinal virtues was the dwarf willow, from an inch to eight inches in length; not the erect willow of our copses, but reclining humbly on the scanty soil in a begging attitude, asking protection against the merciless cold of the long polar night. Nature pursues here a prophylactic course and fills the office of a hygienist and sanitarian rather than that of a physician or druggist. She shuts the door against disease-producing germs, and incorporates in the food on which the natives subsist iodin, the most powerful and least harmful of all known antiseptics. The Eskimos, like all other primitive people, are exceedingly superstitious, and when sick and threatened by death seek help and consolation from unseen sources. They believe in a good and a bad spirit. The former is the departed soul of a father, the latter a monster human being or animal. The latter they look for and sharpen their knives with intent to kill should he be apprehended. Sorcerers (angekoks) are summoned, who implore the good spirit by incantations and a mournful, unceasing, monotonous chant for help. The use of remedies internally or externally is not even thought of. The art of healing has no place in the heart of the Arctic region.

ESKIMO SURGERY.

Surgery among the Eskimos is verily a *lucus a non lucendo.* Fortunately, injuries and surgical affections very seldom afflict them.

Fractures.—The occupation of the Eskimos reduces the causes of fractures and dislocations to a minimum. In case of fracture, the injured limb is wrapped up at once in fur without making any attempt at setting the broken bone. The fur dressing affords some, if not complete, immobilization of the injured limb.

Wounds.—Wounds heal promptly without suppuration under the only dressing in use, the skin of an animal with the bare side directed toward the wound. All of the skins in use by the Eskimos emit a very disagreeable smell and yet they are surgically clean. Suturing of the wounds is unknown to them. At North Star Bay I examined a little girl who had recently been bitten by a dog. The right upper eyelid near the internal canthus of the eye was severed by a vertical tear. The wound was cicatrized with the eyelid almost completely everted. One or two stitches in this case would not only have shortened the time of repair but would have effectually prevented this permanent and annoying deformity. Several cases of gunshot wound that I examined had evidently, judging from the size and appearance of the resulting scars, healed by primary intention. In one case the bullet passed between the fibula and tibia in an antero-posterior direction, without fracturing either of the bones. The scars were small, smooth and movable, and the muscle function was perfect.

Frost-Bite.—Serious forst-bite, freezing of a limb deep enough to cause gangrene, is extremely rare among the Eskimos. Their winter clothing of bear and fox skins and fur or birdskin underclothing, with double fur boots, protects them against the severest cold. When the hands get cold the arms are withdrawn from the sleeves and crossed over the anterior surface of the chest under the coat, where they receive the benefit of the body warmth. The feet are kept warm by keeping the legs in constant motion. This restless condition of the legs becomes a habit to these people, which is kept up, although entirely unnecessary during the summer, particularly by the women. Whether sitting, standing or lying down, the women keep legs and feet busy.

In case of frost-bite the Eskimos proceed to rub the frozen part with snow and slowly thaw it out by body warmth. If it is the hand, the warmth of the chest underneath the fur coat will do it, if it is a foot, the body warmth of a willing sympathizing member of the family or neighbor is brought to bear on the congealed member. By this gradual process of restoring the suspended circulation, serious consequences are usually averted.

Amputation by an Eskimo Woman.—A few years ago the oldest inhabitant of the North Star Bay settlement was out on the ice hunting seal. On firing the old gun, the barrel exploded and a fragment of steel inflicted an ugly wound of the forehead over the right eye. The shock rendered him unconscious. He lay on the ice in this condition for a considerable length of time before he was discovered by one of his fellow hunters, who, with the assistance of others, conveyed him to his igloo, where he recovered consciousness. One of his feet was so badly frozen that gangrene of all the toes and a considerable part of the foot ensued. For weeks the dead toes dangled below the line of demarcation, but the tendons interfered with Nature's efforts to cast off the dead from the living tissues. The patience of the patient finally gave way and he implored his wife to amputate the toes. She consented, took a large knife and in one long sweep severed the dead toes from the granulating stump. The wound has never healed. The end of the stump is now covered with an adherent, thin, bluish scar of very low vitality but nearly the entire plantar surface of the foot is occupied by a chronic ulcer that will never heal. Since this mishap the patient has had to walk on knees and hands in going from place to place until the engineer of the *Erik* made for him a pair of rude crutches, with the aid of which he is now learning to walk erect again (Fig. 2). A gift was never more appreciated than was this one. We cleansed the filthy limb as far as the knee and disinfected the indolent, ill-looking ulcer and supplied the patient with dressing material which will last him a long time, and in the use of which his wife received adequate instruction. As the ulcer will never heal, an amputation is urgently indicated, as it is the only means which will give him permanent relief.

Tumors.—Extensive inquiry and a careful scrutiny of all the Eskimos that came under my personal notice confirm the statements made to me from different sources that there are no tumors of any kind to be found among the inhabitants of this part of the Arctic region. I could not even discover a wart or retention cyst of the appendages of the skin. Lipoma and fibroma, so common in the tropics, are looked for in vain here. Has the highly iodized food of these people anything to do in the prevention of tumors of all sorts, benign and malignant? It seems so to me.

Suppurative Infection.—The very fact that nearly all wounds and abrasions heal by primary union without either treatment or even effective mechanical protection is the strongest and most convincing proof that these people live in an atmosphere and on a soil free from pyogenic bacteria. It is well known, on the other hand, that when the Eskimos come aboard a vessel and take part in loading or unloading cargo, the slightest scratch is liable to give rise to suppuration. It is related on reliable authority that during the Greeley expedition a member of his crew, while at Cape Sabine, suffered from a frost-bite of one of his legs resulting in gangrene which extended as far as the knee. The soft parts sloughed, leaving the bones exposed. He was never taken out of his sleeping bag saturated with his own excretions, and yet no suppuration occurred until, in this condition, he was brought to Godhavn. Here pus formed and he died in consequence of the pyogenic infection. Commander Peary remembers only one case of grave phlegmonous inflammation occurring in an Eskimo. It was in a man who accompanied him on his trip to the most northern part of Greenland in 1900. On the way the right hand and arm became enormously swollen and very painful, and he was so ill that he had to be sent back to Conger. For a long time the swelling and pain continued, when finally over the wrist-joint on the palmar surface of the forearm the swelling ruptured and a large quantity of pus escaped. Suppuration continued for a long time and a second perforation took place near the first one. Both eventually healed and the patient very slowly regained partial use of the hand. I examined this man at Etah. All of the fingers were contracted in a semi-flexed position. Two retracted scars over the wrist-joint marked the places where the deep-seated phlegmonous abscess (suppurative tendo-vaginitis) ruptured and where the scars have become permanently attached to the underlying tendons. Considering that this patient had no treatment of any kind, the functional result must be considered excellent. What dreadful suffering this man must have endured until Nature succeeded, under great difficulties, in eliminating the products of the deep-seated suppurative inflammation, can be better imagined than described. That the streptococci responsible for this fearful infection were imported requires no argument.

Erysipeloid.—Rosenbach's erysipeloid is an inflammation of the superficial lymphatic channels of the skin, which is seen with few exceptions only in persons engaged in the handling of fish and game, butchers, cooks, etc. Our cook on the *Erik* presented a good example of this etiologic and pathologic form of lymphangitis on the up-going trip. The sealers, of which the crew of the *Erik* was almost completely made up, informed me that a somewhat similar affection frequently occurs among the sealers when engaged in their business of killing and handling seal and is known among them as "seal finger." I expected to find erysipeloid among the Eskimos who live exclusively on game. All inquiries in this direction gave uniformly negative information and we must take it for granted that the germ of this disease, as well as the streptococcus of erysipelas, can not thrive in that climate.

ESKIMO MIDWIFERY.

We finally come to a part of the healing art of which the Eskimo knows something and in which he takes an active part—namely, midwifery. When a woman is in the throes of agony of labor, it is very natural that the bystanders, whoever they may be, take by suggestion instinctively, so to say, an active part in the parturient act. To lighten the curse imposed on woman for her indiscretion in the Garden of Eden is the natural dictation of a humane feeling which exists more or less in all classes of men. The Eskimo woman in labor is made the recipient of much attention and is given the willing assistance of one or more women who have learned from experience what it means to bring a new being into the world.

> "All is but lip-wisdom which wants experience."—Sydney.

Family life among the Eskimos of Greenland is an open affair. Privacy does not enter into the igloo and the tent. Within a space not larger than a good-sized family table everything is in common, including the table, which does not exist, and the common family bed, which consists of furs, the number of skins remotely indicating the size of the family. But when the Eskimo woman is about to give birth to a child, the husband, or whoever the prospective father may be, sees to it that the important act takes place in privacy. In summer he fixes a small tent for her exclusive use; in winter he builds a small ice igloo. She enters this private apartment with one or two women who have earned the title of motherhood, and on whom she places reliance during the coming ordeal. The parturient room is supplied with the necessary number of skins. When labor begins she is placed in a squatting position and one woman seated behind her with face toward her back passes her arms around her, clasps hands over her abdomen and when labor pains come on, makes firm compression. If a second woman is present, she takes firm hold of the patient's hands and does her good share of the grunting and straining simultaneously with the uterine contractions. A man gives official notice to the community of what is happening by going from tent to tent or igloo to igloo and with a stick or bone striking the roof with a rap that announces the news without making use of his tongue. When the child is born the officiating midwife takes a sharp stone and severs the cord near the umbilicus. As the cord is not tied, hemorrhage is prevented by dividing it with a dull instrument. The infant is wrapped in fur and is at once placed in the care of its mother. The only remaining function of the midwife consists in tamponing the vagina of the delivered woman, which is done with a bird skin. The woman then takes her child to the family igloo and resumes at once her usual household duties. Should the labor prove to be a protracted one, a small hole is made in the wall of the tent or ice hut, and through this opening food is thrown into the room for its inmates. The mother carries the child in the hood of the fur jacket on her back, next the skin, with its head on a level with or a little above the collar of its mother's fur coat. At night the infant takes its place in the common family bed. The Eskimo women nurse their children until they are two or more years old. When they are three months old they are given their share of blubber. Small pieces are placed in the mouth and they swallow them whole.

I saw many Eskimo infants and all of them were very pictures of health. Seven of them were on the *Roosevelt* when she sailed for the farthest North. Infantile mortality is very small notwithstanding the lack of care bestowed on the newborn. The fur clothing, the mother's body heat and the warmth of the joint family bed protects them against cold and instead of gorging their little stomachs with food prepared by the chemist they thrive on their mother's milk and the simple food Nature has provided for them. Neither children nor adults exhibit any indications of the existence of rachitis.

Judging from the robust appearance of the Eskimo women, I have reason to believe that they are free from uterine and ovarian diseases and that gynecology would be useless in the Arctic regions.

ANIMAL DISEASES.

The only domestic animal the Eskimo knows and owns is the dog, or rather a mixture of dog and wolf. The dog is his beast of burden on which he must rely in traveling over ice and snow. The dog is to him vastly more than the horse is to us, it is—besides his own strength—his only motor power. Commander Peary took with him more than 200 of these beasts on this expedition, and if he succeeds in reaching the pole these faithful animals are entitled to their good share of credit. Nansen, Peary and other Arctic explorers have been seriously hampered in their work by a lack of dogs owing to the breaking out among them of a disease that nearly always proves fatal. The dog population all over Greenland suffers annually great losses from this disease. Neither Nansen nor Peary is satisfied that it is hydrophobia, although many facts and symptoms point that way. The governor of Godhavn, who has seen much of this disease, informed me that there are two distinct clinical types, acute and subacute. In the acute form the animal bites, froths at the mouth and dies within forty-eight hours; in the subacute type the dog sickens, is not vicious, does not froth at the mouth, the hind legs become paralyzed and the animal dies after an illness of about two weeks. If this disease is hydrophobia it is not the same as hydrophobia in other countries, because persons bitten by the sick animals do not contract the disease. Peary's own daughter was bitten by one of the sick dogs, but no ill results followed. The postmortems made on some of Peary's dogs revealed, as the only demonstrable pathologic condition, internal congestion of the mucous membrane of the small intestine, which induced Peary, acting on the supposition that the disease had its origin here, to administer a pint of castor oil to the next dog that sickened. This treatment proved curative, as the animal recovered. That dogs may contract the disease without being bitten by a diseased animal is a well-established fact, and the eliminative treatment would suggest itself the rational one. Loss of dog life from this cause is a source of constant anxiety to all Arctic explorers and of much concern to the natives, whose wealth is proportionate to the number of dogs they own.

Hares, rabbits and dogs are favorite hosts of the tapeworm, and the tapeworm, in turn, is the parasitic cause of echinococcus disease, which is so common in Iceland, Northern Europe and Australia. I took special pains to investigate whether or not tapeworm is present in the intestinal canal of the Eskimo dogs and the Arctic hare. I had more opportunities than I desired to examine the fecal discharges of more than 200 dogs for days on the decks of the *Erik* and *Roosevelt*. Not a trace of this parasite could be found. I killed many Arctic hares and examined their intestinal canals with the same negative result. It thus became clear to me why echinococcus cysts, so prevalent in Iceland, a neighboring island of Greenland, could not be found as one of the few diseases which afflict the Eskimo race. Pondering over this, as well as the numerous other prophylactic measures which Nature employs in protecting these simple, childlike people against disease, I became fully convinced that Providence rules here, like elsewhere, wisely and with forethought, the destinies of man.

IMMUNITY.

CHAPTER XXXII (Concluded).

INFLUENZA.

Influenza occurs sporadically and in epidemics of greater or less proportions. Its extreme contagiousness is shown by the striking rapidity with which it spread over the whole civilized world in the epidemic of 1889 and 1890, leaving behind it a trail of lesser epidemics which have prevailed up to the present time.

Bacillus Influenzæ.

During the epidemic just cited a number of organisms were erroneously described as the cause of the disease. In 1892, however, Pfeiffer discovered a minute bacillus which he found constantly and in large numbers in the sputum of those suffering from influenza, whereas it was absent from other maladies. The observations of Pfeiffer have been confirmed by a large number of investigators, and the organism, *Bacillus influenzæ*, is now generally accepted as the cause of the disease. It is one of the smallest of bacteria (0.2 or 0.3 by 0.5 microns), is non-motile and forms no spores. A medium containing blood or hemoglobin is essential for its artificial cultivation, and even under the best conditions it grows somewhat meagerly and slowly. A number of bloods, but particularly those of man and the dove, favor its growth. It is a strong aërobe. The organism is best stained by a dilute solution of carbol fuchsin (1 to 10), and it shows a property called polar staining, i. e., the ends stain more deeply than the central portion.

Symbiosis.

When the staphylococcus and some other organisms are grown in mixed culture with the influenza bacillus, the latter is stimulated to a more vigorous growth (symbiosis). According to Jacobsohn, killed cultures of the streptococcus greatly increase the virulence of the influenza bacillus when the mixture is injected into animals.

Pseudo-Influenza Bacilli.

Pfeiffer designates as pseudo-influenza bacilli a number of influenza-like organisms which have been found in man and animals. They have the morphology of the influenza bacillus, are a little larger, and also prefer a medium which contains hemoglobin, but since some of them occur in animals which are known not to be susceptible to influenza, it is concluded that they can not be identical with the influenza bacillus. The influenza-like bacillus which Jochmann and Krause consider as the cause of whooping-cough, may be mentioned in this connection.

Resistance and Virulence.

The resistance of the bacillus to desiccation, sunlight and unfavorable temperatures is very low. It dies in from twenty-four to thirty-six hours at room temperature, when contained in sputum, and lives for about thirty-two hours in hydrant water (Pfeiffer). It is not highly virulent for experiment animals, although a condition said to resemble influenza has been produced in monkeys by placing pure cultures on the nasal mucous membrane. Fatal infections may be produced by intravenous inoculation of the bacillus into monkeys and rabbits, and killed cultures produce a fatal intoxication in rabbits. When virulent cultures are injected into the peritoneal cavity of guinea-pigs in sufficient quantity, the bacilli proliferate, and peritonitis ending fatally is produced. Since the bacilli seem not to proliferate when fatal quantities are injected intravenously into rabbits, and since fatal intoxication, without the occurrence of bacteriemia, may take place when a tracheal infection is induced in the ape (Pfeiffer), it is concluded that the toxic phenomena of influenza are due to the absorption of bacterial toxins from the mucous surfaces. A soluble toxin has not been obtained in culture media. The organism is a facultative pus producer.

Distribution in the Body.

So far as is known the influenza bacillus is excreted only with the secretions of infected surfaces, i. e., from the upper respiratory passages, conjunctiva, ear, etc. The belief, commonly held, that the influenza bacillus does not enter the circulation is based on the fact that cultures have not been obtained from the blood (Beck). That this may be an erroneous belief is suggested by a case of fatal influenza peritonitis reported by Hill and Fisch, in which the latter cultivated the organism in large quantities from the spleen. When the bacilli reach the blood it is probable that they are killed quickly. That metastatic infection is possible, however, either by way of the lymph or blood channels, is shown by the occurrence of influenza meningitis, and, rarely, of influenza peritonitis. It is probable that the ordinary nervous phenomena of the disease are due to intoxication rather than to actual infection of the nervous structures. As to whether the symptoms of so-called intestinal influenza are due to an invasion of the intestines by the bacilli or to a specialized action of circulating toxin seems not to have been definitely settled. There certainly is abundant opportunity for infection of the intestines in cases of bronchial influenza. In the bronchitis of influenza the organisms are found in large numbers in the smaller bronchial tubes, both free and within leucocytes; hence, in searching for the bacilli clinically it should be certain that the sputum examined represents the bronchial exudate. In influenza pneumonia, which usually is of the lobular type, the bacilli, mixed with pus cells and contained in them are found in large numbers in the alveoli. Pure cultures of the bacillus have been obtained from cases of conjunctivitis, and they occur not infrequently in middle ear complications which develop during the course of the disease. Influenza conjunctivitis sometimes occurs in epidemic form, particularly in institutions and schools.

Mixed Infections.

Pneumonic foci which develop during influenza frequently show the pneumococcus, and sometimes the streptococcus or the bacillus of Friedlander in addition to the influenza bacillus, and similar mixed infections occur in pleurisy and in middle-ear disease. Influenza may be superimposed on other infections; individuals suffering from pulmonary tuberculosis are particularly susceptible to influenza and in them the prognosis is unfavorable.

Transmission, Infection Atria and Prophylaxis.

The disease is transmitted directly from man to man and, chiefly, it is supposed, by means of infected droplets of sputum which are expelled in coughing and sneezing. Obviously kissing affords opportunity for infection. Infection by indirect contact is of less importance because of the rapid death of the bacillus after it leaves the body, but living germs may well be disseminated by soiled handkerchiefs or other contaminated linen. Dust infection possibly is of minor consequence. Chronic influenza in which the bacilli may persist in the bronchi for weeks, and cause recurrent acute attacks, is of importance for the maintenance of an epidemic. Particularly in tuberculous cavities the bacilli may flourish for long periods.

Primary infection takes place in the upper respi[illegible] passages, and the disease readily extends from one p[illegible] [illegible]her
as from the nose to the pulmonary tissue. In[illegible] [illegible]he
ear usually is a complication of pharyngeal or [illegible]
fection. Occasionally an influenza conjunctivitis i[illegible]

ity of a nat[illegible] exp[illegible]
teaches that
ble. The beli[illegible]
ing children a[illegible]
people seems to
perience, althoug[illegible]
are not entirely immune. Influen[illegible]
infection in which one attack creates a predisposition for a second, but the truth of this is doubted by many who have had extensive experience with the disease. Wutzdorff, in a study of the epidemic which prevailed in Germany during 1891-92, finds in the small number of cases, the irregularity of their distribution, and comparative exemption of rather large districts, reasons for believing that one attack confers a degree of acquired immunity; that is to say, the population had been so thoroughly infected (*durchgeseucht*) during the preceding year or two that comparatively few remained who were susceptible, although the disease itself appeared to be more malignant than in the previous year (cited from Beck). However, the occurrence of second attacks shortly after the first, and the occurrence of repeated infections in some individuals, are sufficiently well known, hence it seems fairly clear that immunity which may result from infection is of short duration. The aged, those of low vitality, and those with pulmonary tuberculosis, have low resistance to infection.

Serum Properties.

Although Delius and Kolle were able to produce a slight increase in the resistance of guinea-pigs by the intraperitoneal injection of cultures, nothing like a well-marked immunity was obtained; nor did the serum of immune animals or convalescent man show any increased protective power for other animals. Slatinéano, however, obtained serum of some protective power for guinea-pigs, by the immunization of rabbits and guinea-pigs, but it had no curative effect. The results of Cantani were similar, and both observers noted the development of bactericidal power, as determined by the Pfeiffer reaction, and of agglutinins. At the present time there seems little to hope from vaccination.

There is said to be some increase in agglutinins in man as a consequence of infection. The agglutinating power of the serum of an immunized animal may be as high as 1 to 500 (Cantani).

SOFT CHANCRE.

The independence of soft chancre from syphilis, and its infectiousness by inoculation with the purulent secretions of the ulcers, were established long ago. Rollet found that filtered pus lost its infectiousness.

Bacillus of Ducrey.

A large number of observers had found bacteria of one kind or another in the pus and in stained sections of the walls of the ulcers, and probably some of them (e. g., Unna), had seen the bacillus which Ducrey described (1889) and later cultivated, and which is now proved to be the cause of the disease. The bacillus is very small (0.4x1.5 microns), is non-motile and shows polar staining. It resembles the plague bacillus in form, but is somewhat smaller, and does not show the extensive involution forms of the latter. In the ulcer it lies singly, in small groups, or more characteristically in the form of bands, made up of two or more parallel chains, which pen[illegible]te the wall of the ulcer. Large numbers are often
fo[illegible] [illegible]he polymorphonuclear leucocytes of the pus, particu-

CHAPTER XXXIII.

PNEUMOCOCCUS INFECTIONS.

PNEUMONIA.

Organisms Causing Pneumonia.

Although there are several types of pneumonia or pulmonitis, no one organism is the exclusive cause of any one type, except perhaps the viruses of syphilis and tuberculosis, and any organism which can cause pneumonia can also set up inflammations in other organs. The following organisms are known to cause acute pulmonitis: *Diplococcus pneumoniæ*, *Streptococcus pyogenes*, *Staphylococcus pyogenes*, bacillus of Friedlander (*B. pneumoniæ*), *B. influenzæ*, *B. pestis*, *B. diphtheriæ*, *B. typhosus*, *B. coli communis*, and *Micrococcus catarrhalis*. The organisms of tuberculosis, actinomycosis, the virus of syphilis and of some other infections cause chronic inflammations of the lungs. Some of these organisms have already been considered and others will be briefly discussed later, in their relation to pneumonia, without, however, entering into details as to the various types of the disease.

Diplococcus Pneumoniæ.

The *Diplococcus pneumoniæ* is the commonest cause of lobar pneumonia, and not infrequently produces lobular pneumonia, and has been found as the only organism in acute interstitial pneumonia (Weichselbaum). Friedlander (1882) found that capsulated cocci were present constantly in the exudate of pneumonia. Such cocci in all probability represented the organism which at present is known as the diplococcus of pneumonia, yet the cultures which he obtained somewhat later showed the characteristics of the organism now known as the bacillus of Friedlander. Fraenkel in 1884 obtained the first named coccus in pure culture, and his investigations, together with those of Weichselbaum and many others, eventually established the independence of the two organisms, and showed that the pneumococcus is the most frequent cause of pneumonia, but that other organisms, including the bacillus of Friedlander, may occasionally produce the disease.

Typical and Non-Typical Strains.

The typical pneumococcus is slightly elongated, and both in the tissues and in culture media it grows in pairs. Typically, also, the pair possesses a capsule which is present constantly in the tissues and may be obtained on certain culture media, as milk and serum. It is non-motile, non-flagellated, forms no spores and stains by Gram's method. Rather scant growth occurs on the ordinary culture media in the form of small colonies which resemble those of the streptococcus, and unless special media are used it usually can not be carried through many generations. When grown in sputum, or on a medium which contains the blood or serum of man or some other favorable animal, it may be preserved for many months in a fairly high state of virulence. By growth at 39° C. virulence is lost rapidly. Strains which are atypical in one of several ways are encountered not infrequently. Such strains may show a low virulence, may grow well at ordinary temperatures (the typical organism not doing so), may produce long chains in liquid media, or may grow without a capsule.

Confusion with Streptococcus.

Recently the danger of confusing the pneumococcus with the streptococcus has received renewed attention, and newer methods of differentiation render it extremely probable that such confusion has occurred in the past. An important differential method is that of growing these organisms on agar plates which contain blood (Schottmüller); the *streptococcus* produces a clear zone of hemolyzed corpuscles about its colonies, whereas the colonies of the pneumococcus present a greenish color and produce no hemolysis. *In using this test* Ruediger found a surprising number of pneumococci *in normal* throats, whereas previous work had shown them to be much less common than streptococci.

Resistance.

In spite of the poor viability of the organism *on ordinary* culture media, it is fairly resistant to desiccation and sunlight, especially when imbedded in sputum. *It is* possible that the sputum forms a protective coating about the organism and that the well-formed capsule which it possesses as a parasite, increases its resistance. Like other bacteria, it resists diffuse sunlight better than direct, and in the former may live for as long as fifty-five days in a dried state (Bordoni-Uffreduzzi, cited by Weichselbaum). It has very little resistance to heat, being killed by a temperature of 52° C. for ten minutes. Virulence is lost rather quickly in ordinary culture media, but is retained longer when grown in sputum or media which contains serum or ascitic fluid.

Toxic Properties.

No soluble toxin characteristic for the organism has been obtained, although more or less poisonous substances, some of them of a chemical nature have been described. Presumably the toxic properties depend on the presence of an endotoxin. The pneumotoxin of F. and G. Klemperer was prepared by precipitation with alcohol. The pneumococcus is a pyogenic organism and causes exudates which are rich in fibrin. Occasionally serous rather than purulent exudates are produced. Its toxic action is directed toward various organs, and it is doubtful if any of the tissues of the body are non-susceptible. Some strains are supposed to be more neurotoxic than others.

Susceptibility of Animals.

The susceptibility of animals varies greatly. Rabbits and mice are extremely susceptible and are used as test animals for the identification of the organism. Other laboratory animals have greater resistance, and the pigeon and chicken are almost absolutely immune. In susceptible animals a rapidly fatal coccemia or more or less extensive local lesions are produced, depending on the virulence of the culture, the seat of inoculation and the susceptibility of the animal. In rabbits lobar pneumonia has been produced by inoculation into the pleura, trachea, blood stream or subcutaneous tissue.

Occurrence in the Body.

The pneumococcus is present in the nose, mouth and pharynx of a large percentage of individuals. It is found frequently in the conjunctiva and occasionally in the deeper air passages. That it may reach the stomach and intestines with the sputum is apparent, and it has been found there as the cause of diphtheritic enteritis, a condition which may be followed by pneumococcus peritonitis or general infection.

Entrance into the Lungs.

In the production of lobar *pneumonia it is believed that the* organisms are carried into the lungs by inhalation in most instances. Suspended in droplets of saliva or *mucus, or adherent to foreign particles, they* may be carried fairly deeply into the bronchial tubes. That they ever reach the alveoli by this *means* alone is questioned by many. Two factors would *seem to prevent their* being carried to the alveoli by currents of inspired air: First, foreign particles or infected *droplets are likely* to strike and adhere to the walls of the *respiratory passages* before they have traversed a great length, and from this situation may again be carried out by the action *of the ciliated* epithelium or coughing; the tortuous passages *of the* nose and its hairs and moist surfaces undoubtedly arrest many micro-organisms. Second, the velocity of the inspired air is greatly reduced or is nil by the time the particles *might* have reached the alveoli, a condition which renders their arrest all the more probable. Nevertheless, pneumococci do reach the alveoli, and by some it is supposed that even in health they are carried there more or less constantly and are as constantly destroyed. They have *occasionally* been found in the parenchymatous tissue of the lungs of individuals *who have* died of other than pneumococcal infections or of non-infectious diseases. In order *to* show that *micro-organisms* may be carried into the parenchyma by inspiration Nenninger *allowed* animals to inhale a spray containing *Micrococcus prodigiosus*, and killing the animals after *one-half* hour was able to cultivate the coccus from the base *of the* lungs where only alveoli and the finest bronchial branches were present (cited by Weichselbaum).

Lymphogenous and Hematogenous Infection.

Various other agencies have been suggested by which the cocci may be carried to the parenchymatous tissue. For example, during the forced respiratory efforts which accompany *coughing* they may be carried from the bronchial branches into the alveoli. Or the organisms having reached the bronchi, in some way may be carried through the walls of the latter, perhaps by the leucocytes, and reach the alveoli directly through the lymph chantained from the blood (Beck). That this may be an erroneous belief is suggested by a case of fatal influenza peritonitis reported by Hill and Fisch, in which the latter cultivated the organism in large quantities from the spleen. When the bacilli reach the blood it is probable that they are killed quickly. That metastatic infection is possible, however, either by way of the lymph or blood channels, is shown by the occurrence of influenza meningitis, and, rarely, of influenza peritonitis. It is probable that the ordinary nervous phenomena of the disease are due to intoxication rather than to actual infection of the nervous structures. As to whether the symptoms of so-called intestinal influenza are due to an invasion of the intestines by the bacilli or to a specialized action of circulating toxin seems not to have been definitely settled. There certainly is abundant opportunity for infection of the intestines in cases of bronchial influenza. In the bronchitis of influenza the organisms are found in large numbers in the smaller bronchial tubes, both free and within leucocytes; hence, in searching for the bacilli clinically it should be certain that the sputum examined represents the bronchial exudate. In influenza pneumonia, which usually is of the lobular type, the bacilli, mixed with pus cells and contained in them are found in large numbers in the alveoli. Pure cultures of the bacillus have been obtained from cases of *conjunctivitis*, and they occur not infrequently in middle ear complications which develop during the course of the disease. Influenza conjunctivitis sometimes occurs in epidemic form, particularly in institutions and schools.

Mixed Infections.

Pneumonic foci which develop during influenza frequently show the pneumococcus, and sometimes the streptococcus or the bacillus of Friedlander in addition to the influenza bacillus, and similar mixed infections occur in pleurisy and in middle-ear disease. Influenza may be superimposed on other infections; individuals suffering from pulmonary tuberculosis are particularly susceptible to influenza and in them the prognosis is unfavorable.

Transmission, Infection Atria and Prophylaxis.

The disease is transmitted directly from man to man and, chiefly, it is supposed, by means of infected droplets of sputum which are expelled in coughing and sneezing. Obviously kissing affords opportunity for infection. Infection by indirect contact is of less importance because of the rapid death of the bacillus after it leaves the body, but living germs may well be disseminated by soiled handkerchiefs or other contaminated linen. Dust infection possibly is of minor consequence. Chronic influenza in which the bacilli may persist in the bronchi for *weeks*, and cause recurrent acute attacks, is of importance for the maintenance of an epidemic. Particularly in tuberculous cavities the bacilli may flourish for long periods.

Primary infection takes place in the upper respiratory passages, and the disease readily extends from one part to another as from the nose to the pulmonary tissue. Infection of the ear usually is a complication of pharyngeal or pulmonary infection. Occasionally an influenza conjunctivitis is found without other localization of the infection. "Primary" infection of other organs, as the brain and peritoneum, are metastatic, although the original focus or atrium may not be observed.

Little or nothing can be done in the way of general prophylaxis. Washing of the nose and mouth with antiseptics during an epidemic may reasonably be practiced, but with what success is uncertain. The aged and those of low vitality should avoid exposure to infection, for in them the severer complications, such as pneumonia, are more likely to occur. When influenza conjunctivitis appears epidemically in schools the latter *should* be closed or the infected children excluded.

Immunity, Susceptibility and Recurrences.

Although little or nothing is known concerning the possibility of a natural immunity in man, experience teaches that he is on the whole very susceptible. The belief expressed by some that nursing children *are* less susceptible than older people seems to have some foundation in experience, although it is well known that they are not entirely immune. Influenza is sometimes cited as an infection in which one attack creates a predisposition for a second, but the truth of this is doubted by many who have had extensive experience with the disease. Wutzdorff, in a study of the epidemic which prevailed in Germany during 1891-92, finds in the small number of cases, the irregularity of their distribution, and comparative exemption of rather large districts, reasons for believing that one attack confers a degree of acquired immunity; that is to say, the population had been so thoroughly infected (*durchgeseucht*) during the preceding year or two that comparatively few remained who were susceptible, although the disease itself appeared to be more malignant than in the previous year (cited from Beck). However, the occurrence of second attacks shortly after the first, and the occurrence of repeated infections in some individuals, are sufficiently well known, hence it seems fairly clear that immunity which may result from infection is of short duration. The aged, those of low vitality, and those with pulmonary tuberculosis, have low resistance to infection.

Serum Properties.

Although Delius and Kolle were able to produce a slight increase in the resistance of guinea-pigs by the intraperitoneal injection of cultures, nothing like a well-marked immunity was obtained; nor did the serum of immune animals or convalescent man show any increased protective power for other animals. Slatinéano, however, obtained serum of some protective power for guinea-pigs, by the immunization of rabbits and guinea-pigs, but it had no curative effect. The results of Cantani were similar, and both observers noted the development of bactericidal power, as determined by the Pfeiffer reaction, and of agglutinins. *At the present time there* seems little to hope from vaccination.

There is said to be some increase in agglutinins in man as a consequence of infection. The agglutinating power of the serum of an immunized animal may be as high as 1 to 500 (Cantani).

SOFT CHANCRE.

The independence of soft chancre from syphilis, and its infectiousness by inoculation with the purulent secretions of the ulcers, were established long ago. Rollet found that filtered pus lost its infectiousness.

Bacillus of Ducrey.

A large number of observers had found bacteria of one kind or another in the pus and in stained sections of the walls of the ulcers, and probably some of them (e. g., Unna), had seen the bacillus which Ducrey described (1889) and later cultivated, and which is now proved to be the cause of the disease. The bacillus is very small (0.4x1.5 microns), is non-motile and shows polar staining. It resembles the plague bacillus in form, but is somewhat smaller, and does not show the extensive involution forms of the latter. In the ulcer it lies singly, in small groups, or more characteristically in the form of bands, made up of two or more parallel chains, which penetrate the wall of the ulcer. Large numbers are often found in the polymorphonuclear leucocytes of the pus, particularly in an early stage of the lesion (Kroefting). Great difficulty was encountered in cultivating the bacillus and Ducrey's first success was obtained with a medium which contained human skin. It has since been cultivated on agar which contains the blood or serum of man, rabbit or dog. Himmel attempted to cultivate it in the fresh defibrinated *blood* of the guinea-pig, but was unsuccessful because the bacilli were phagocytized by the leucocytes (Babes).

An ulcer resembling that of soft chancre may be produced in the ape, and also in the cat, by the inoculation of pure cultures. Didey reinoculated man from the ulcers of the cat. When living cultures are injected into *the* guinea-pig (peritoneal cavity, subcutaneous tissue, dura mater), the bacilli are quickly taken up by leucocytes and digested (Himmel). Himmel reports having so decreased the resistance of guinea-pigs by peritoneal injections of lactic acid that they became susceptible to infection. After two or three passages the culture became so virulent that fatal *bacteriemia* was caused without previously lowering the resistance of *the* animal.

In man the infection is transmitted to the *inguinal* lymph glands, but never becomes general.

CHAPTER XXXIII.

PNEUMOCOCCUS INFECTIONS.

PNEUMONIA.

Organisms Causing Pneumonia.

Although there are several types of pneumonia or pulmonitis, no one organism is the exclusive cause of any one type, except perhaps the viruses of syphilis and tuberculosis, and any organism which can cause pneumonia can also set up inflammations in other organs. The following organisms are known to cause acute pulmonitis: *Diplococcus pneumoniæ, Streptococcus pyogenes, Staphylococcus pyogenes*, bacillus of Friedlander (*B. pneumoniæ*), *B. influenzæ, B. pestis, B. diphtheriæ, B. typhosus, B. coli communis,* and *Micrococcus catarrhalis.* The organisms of tuberculosis, actinomycosis, the virus of syphilis and of some other infections cause chronic inflammations of the lungs. Some of these organisms have already been considered and others will be briefly discussed later, in their relation to pneumonia, without, however, entering into details as to the various types of the disease.

Diplococcus Pneumoniæ.

The *Diplococcus pneumoniæ* is the commonest cause of lobar pneumonia, and not infrequently produces lobular pneumonia, and has been found as the only organism in acute interstitial pneumonia (Weichselbaum). Friedlander (1882) found that capsulated cocci were present constantly in the exudate of pneumonia. Such cocci in all probability represented the organism which at present is known as the diplococcus of pneumonia, yet the cultures which he obtained somewhat later showed the characteristics of the organism now known as the bacillus of Friedlander. Fraenkel in 1884 obtained the first named coccus in pure culture, and his investigations, together with those of Weichselbaum and many others, eventually established the independence of the two organisms, and showed that the pneumococcus is the most frequent cause of pneumonia, but that other organisms, including the bacillus of Friedlander, may occasionally produce the disease.

Typical and Non-Typical Strains.

The typical pneumococcus is slightly elongated, and both in the tissues and in culture media it grows in pairs. Typically, also, the pair possesses a capsule which is present constantly in the tissues and may be obtained on certain culture media, as milk and serum. It is non-motile, non-flagellated, forms no spores and stains by Gram's method. Rather scant growth occurs on the ordinary culture media in the form of small colonies which resemble those of the streptococcus, and unless special media are used it usually can not be carried through many generations. When grown in sputum, or on a medium which contains the blood or serum of man or some other favorable animal, it may be preserved for many months in a fairly high state of virulence. By growth at 39° C. virulence is lost rapidly. Strains which are atypical in one of several ways are encountered not infrequently. Such strains may show a low virulence, may grow well at ordinary temperatures (the typical organism not doing so), may produce long chains in liquid media, or may grow without a capsule.

Confusion with Streptococcus.

Recently the danger of confusing the pneumococcus with the streptococcus has received renewed attention, and newer methods of differentiation render it extremely probable that such confusion has occurred in the past. An important differential method is that of growing these organisms on agar plates which contain blood (Schottmüller); the streptococcus produces a clear zone of hemolyzed corpuscles about its colonies, whereas the colonies of the pneumococcus present a greenish color and produce no hemolysis. In using this test Ruediger found a surprising number of pneumococci in normal throats, whereas previous work had shown them to be much less common than streptococci.

Resistance.

In spite of the poor viability of the organism on ordinary culture media, it is fairly resistant to desiccation and sunlight, especially when imbedded in sputum. It is possible that the sputum forms a protective coating about the organism and that the well-formed capsule which it possesses as a parasite, increases its resistance. Like other bacteria, it resists diffuse sunlight better than direct, and in the former may live for as long as fifty-five days in a dried state (Bordoni-Uffreduzzi, cited by Weichselbaum). It has very little resistance to heat, being killed by a temperature of 52° C. for ten minutes. Virulence is lost rather quickly in ordinary culture media, but is retained longer when grown in sputum or media which contains serum or ascitic fluid.

Toxic Properties.

No soluble toxin characteristic for the organism has been obtained, although more or less poisonous substances, some of them of a chemical nature have been described. Presumably the toxic properties depend on the presence of an endotoxin. The pneumotoxin of F. and G. Klemperer was prepared by precipitation with alcohol. The pneumococcus is a pyogenic organism and causes exudates which are rich in fibrin. Occasionally serous rather than purulent exudates are produced. Its toxic action is directed toward various organs, and it is doubtful if any of the tissues of the body are non-susceptible. Some strains are supposed to be more neurotoxic than others.

Susceptibility of Animals.

The susceptibility of animals varies greatly. Rabbits and mice are extremely susceptible and are used as test animals for the identification of the organism. Other laboratory animals have greater resistance, and the pigeon and chicken are almost absolutely immune. In susceptible animals a rapidly fatal coccemia or more or less extensive local lesions are produced, depending on the virulence of the culture, the seat of inoculation and the susceptibility of the animal. In rabbits lobar pneumonia has been produced by inoculation into the pleura, trachea, blood stream or subcutaneous tissue.

Occurrence in the Body.

The pneumococcus is present in the nose, mouth and pharynx of a large percentage of individuals. It is found frequently in the conjunctiva and occasionally in the deeper air passages. That it may reach the stomach and intestines with the sputum is apparent, and it has been found there as the cause of diphtheritic enteritis, a condition which may be followed by pneumococcus peritonitis or general infection.

Entrance into the Lungs.

In the production of lobar pneumonia it is believed that the organisms are carried into the lungs by inhalation in most instances. Suspended in droplets of saliva or mucus, or adherent to foreign particles, they may be carried fairly deeply into the bronchial tubes. That they ever reach the alveoli by this means alone is questioned by many. Two factors would seem to prevent their being carried to the alveoli by currents of inspired air: First, foreign particles or infected droplets are likely to strike and adhere to the walls of the respiratory passages before they have traversed a great length, and from this situation may again be carried out by the action of the ciliated epithelium or coughing; the tortuous passages of the nose and its hairs and moist surfaces undoubtedly arrest many micro-organisms. Second, the velocity of the inspired air is greatly reduced or is nil by the time the particles might have reached the alveoli, a condition which renders their arrest all the more probable. Nevertheless, pneumococci do reach the alveoli, and by some it is supposed that even in health they are carried there more or less constantly and are as constantly destroyed. They have occasionally been found in the parenchymatous tissue of the lungs of individuals who have died of other than pneumococcal infections or of non-infectious diseases. In order to show that micro-organisms may be carried into the parenchyma by inspiration Nenninger allowed animals to inhale a spray containing *Micrococcus prodigiosus*, and killing the animals after one-half hour was able to cultivate the coccus from the base of the lungs where only alveoli and the finest bronchial branches were present (cited by Weichselbaum).

Lymphogenous and Hematogenous Infection.

Various other agencies have been suggested by which the cocci may be carried to the parenchymatous tissue. For example, during the forced respiratory efforts which accompany coughing they may be carried from the bronchial branches into the alveoli. Or the organisms having reached the bronchi, in some way may be carried through the walls of the latter, perhaps by the leucocytes, and reach the alveoli directly through the lymph channels or after having caused infection in the peribronchial lymph glands. Others express the opinion that pneumonia follows blood infection in many or most instances, i. e., that the infection is hematogenous, the cocci having reached the blood in some obscure manner. That the infection may be hematogenous is shown by the occasional occurrence of pneumonia secondary to pneumococcus infection in other parts of the body. These theories are sufficiently reasonable, but, unfortunately, little positive proof of their correctness is at hand.

Conditions for Infection.

Knowing the fairly constant presence of pneumococci in the upper respiratory passages in the normal individual, it seems certain that some unusual condition must arise to precipitate infection of the pulmonary tissue. Concerning the exact nature of these conditions or changes, we have at present little but theories. Manifestly they may rest either with the microbe or the individual, or with both. The pneumococci on the mucous surfaces for some unknown reason may undergo an increase in virulence preceding infection, or more virulent organisms from the outer world, or from pneumonic patients, may be inhaled. The latter condition is an important one in relation to the contagiousness of pneumonia and the development of epidemics. Park and Williams found a larger percentage of virulent organisms in the sputum of pneumonics than in that of normal persons. It is possible that the pneumococcus in being passed from one patient to another undergoes an increase in virulence, similar to the increase which may be obtained by passing bacteria through animals.

Decrease of Resistance.

On the other hand, it is very probable that essential changes take place in the individual, changes which in some may cause the lowered resistance which is so often referred to as a condition for infection. Exposure to cold has long been known as an important predisposing factor, although we continue in ignorance of its precise effects. Experimentally it has been shown that animals are more susceptible to pneumococcus infection after artificial reduction of the body temperature. It is possible that a lowered body temperature may decrease antibacterial activities; that the activity of the bactericidal ferments of the plasma or of the leucocytes may be suppressed, or phagocytosis may be inhibited so that organisms which reach the bronchi and peribronchial lymphatic structures are allowed to proliferate. It is probable that in health the leucocytes continuously pass through the bronchial and alveolar walls where they may englobe foreign particles (coal dust) or bacteria and leucocytes are present on the mucous membranes of the mouth cavity. Following exposure and the reduction of the body temperature, or following the prolonged inspiration of cold air, the activity of the phagocytes may be inhibited so that cocci which reach these surfaces are not ingested and continue to proliferate, or the same conditions may decrease the exudation of the leucocytes from the vessels. It is possible also that the activity of the ciliated epithelium is reduced similarly so that the cocci are not so readily carried to the exterior.

Other Predisposing Factors.

Extreme exposure is not always followed by pneumonia, however, and not all cases of pneumonia are preceded by exposure; many other conditions may predispose to infection, as a lowered resistance due to alcoholism, other infections or to non-infectious processes. That certain local conditions may favor infection is indicated by the frequency with which individuals with chronic tuberculosis of the lungs die of pneumococcus pneumonia, and the development of the disease in areas of hypostatic congestion. Age is of influence. "To the sixth year the predisposition to pneumonia is marked; it diminishes to the fifteenth year, but then for each subsequent decade it increases" (Osler). The cause of these variations is not known, although the rise in later years may be associated with increased exposure.

The conditions which predispose to infection are now the subject of active study in many laboratories, and the commission which the New York Department of Health has established for the study of acute respiratory diseases has already made important observations as to the prevalence and virulence of pneumococci.

Complications.

Many observers have found pneumococci in the blood in a large percentage of the cases, and recent work by Rosenow indicates that the blood is probably infected in all cases at some stage of the disease. This being the case, the frequency with which pneumococcus infections occur in other organs as complications of the disease is readily understood. Pleuritis is present almost constantly, pericarditis frequently, and the peritoneal cavity is invaded not infrequently by way of the diaphragm, with general peritonitis as the occasional result. Endocarditis, meningitis and arthritis are frequent complications. Conjunctivitis, otitis media, cutaneous or subcutaneous infections, intramuscular abscesses and osteomyelitis may develop, and the kidneys and liver usually show acute degenerations.

Diplococcus pneumonia occurs as a complication in typhoid, diphtheria, tuberculosis, influenza, erysipelas and other infections, the organism of the primary infection also being found in the lungs. Not infrequently staphylococci or streptococci, or the bacillus of Friedlander, are found together with the pneumococcus, the latter being the predominating organism.

Prophylaxis.

Prophylactic measures are largely of an individual character and in the main they are suggested by what has been said. One should not come in contact unnecessarily with those suffering from pneumonia. The susceptible should be guarded against exposure; in hospitals pneumonia should be considered as a contagious disease, the cases isolated as such, and the sputum disinfected; expectoration in public places should be limited. To what extent the dust-laden atmosphere which prevails in most of our large cities is a factor in causing pneumonia is unknown. Vaccination is not yet an established procedure.

Immunity and Susceptibility.

It is probable that the susceptibility of man varies greatly. Under equal conditions of exposure not all contract pneumonia, and an individual who eventually contracts the disease may have undergone many similar exposures previously. Klemperer introduced a culture of the pneumococcus which was virulent for rabbits under his skin without suffering more than temporary disturbance.

Recovery.

Recovery seems to indicate an acquired immunity or resistance which is by no means permanent, and often is of very short duration. One may have as many as eight or ten attacks of pneumonia, the intervals between attacks being from three to five years on the average (Griswolle). What the recovery or acquired resistance depends on is unknown. The marked leucocytosis of pneumonia, and the known phagocytic power of the leucocytes for the diplococcus, suggest strongly the importance of the leucocytes for recovery. The serums of convalescents and of immune animals show no increased bactericidal power for the organism, nor are they strikingly antitoxic.

Serum Properties and Opsonins.

Beginning with Fraenkel (1886), many have shown the possibility of increasing the resistance of susceptible animals to the pneumococcus by injecting first dead or avirulent and then virulent cultures; in this way the subjects can be made to withstand many multiples of the minimum fatal dose. Culture filtrates and precipitates (the pneumotoxin of F. and G. Klemperer) have been used for similar purposes. The serum of immune animals, and in some instances of convalescents, has been found to have a protective effect when injected into other animals, and by some a curative effect is claimed when the serum is given shortly after infection. Mennes made the interesting observation that "normal leucocytes only become phagocytic toward pneumococci when they are lying in the serum of an animal immunized against this bacterium" (Muir and Ritchie). This action may have been due to the effect of the opsonins which Wright and Douglass have shown to be essential for phagocytosis of the pneumococci. According to Neufeld and Rimpau, antipneumococcus serum is not bactericidal, but through the influence of bacteriotropic substances (opsonins ?) which it contains renders the cocci more susceptible to phagocytosis.[1] Likewise, Park and Williams found antipneumococcus serum from the sheep to be protective for mice and to stimulate phagocytosis. The correspondence between bacteriotropic action and protective power was variable, however, so that it did not appear certain that the protective power of the serum was due entirely to its influence on phagocytosis. We are, of course, not sure that events in the animal body correspond with those in the test glass.

---

[1] This bacteriotropic substance, according to Neufeld, differs from the opsonin of Wright in that it is not destroyed by low degrees of heat.

Serum Therap and Agglutination.

Some of the serums which have been prepared have been used therapeutically in man. The results have not been sufficiently satisfactory to put them on a good basis, although some favorable reports have been given. The serum of pneumonic patients shows an increased agglutinating power for the pneumococcus. The maximum is reached at or near the time of crisis, but rarely has a higher value than 1 to 50 to 1 to 60 (Neufeld, Rosenow). It disappears quickly after recovery. In immunized animals the agglutinating power may be pushed to much higher limits. Not all strains yield agglutinins equally, and not all are agglutinated equally by the same serum. According to Collins, pneumococci fall into different groups, depending on their agglutinating properties; the same author determined the presence of group agglutinins in an immune serum. Neufeld states that avirulent strains were not agglutinated by the serum of pneumonic patients.

OTHER INFECTIONS BY THE PNEUMOCOCCUS.

Complicating infections by the pneumococcus during the course of pneumonia were mentioned above. They may occur by way of the lymph channels, as in pleuritis, pericarditis and peritonitis (through the diaphragm), by contiguous extension, as in infection of the bronchi, nose and, perhaps, the middle ear, or as metastatic infections following the invasion of the blood stream by the organisms. It is undoubtedly in the last named manner that meningitis, endocarditis, arthritis, muscular and subcutaneous abscesses arise.

Mode of Infection.

Other infections by the pneumococcus occur independent of the existence of pneumonia. Such conditions are alveolar abscesses, conjunctivitis, dachryocystitis, serpent ulcer of the cornea, inflammation of the middle ear, meningitis, enteritis, rarely peritonitis, and pneumococcus septicemia which may be complicated by infection in various organs. The eye is exposed to infection from without and the ear from the pharynx. The meninges may be infected by way of the middle ear or the nose, or the organisms may gain entrance through the circulation from a primary focus in another organ, perhaps an undiscovered focus. Infection of the peritoneum may follow an intestinal infection; a pure pneumococcus infection of the peritoneum in the absence of pneumonia is extremely rare. Pneumococcus infections of the eye, ear, intestines and peritoneum are likely to be accompanied by other organisms.

Pneumococcus conjunctivitis occurs in epidemic form and the same precautions should be taken to limit it as for the limitation of influenza conjunctivitis.

Serpent ulcer of the eye, a progressive phagedenic process in the cornea, has the pneumococcus as its essential cause, although other organisms may be present. Roemer treats the condition with an antipneumococcus serum and claims that he is able to arrest the process if the treatment is begun sufficiently early. The serum is injected beneath the conjunctiva.

Clinical Reports

A CASE OF ACCIDENTAL ESERIN (PHYSOSTIGMIN) POISONING WITH RECOVERY.

B. F. STEVENS, M.D.
EL PASO, TEXAS.

Patient.—A woman, aged 28, because of a mistake in telephoning a prescription, received a dose of two grains of eserin sulphate hypodermically, instead of a fiftieth of a grain as was intended.

History.—I had operated on this patient four hours previously for a double pyosalpinx, and gave the eserin to aid in passing flatus. An hour before receiving the eserin she had been given morphin, 1/8 grain, with atropin, 1/200 grain, for pain. Within two or three minutes after receiving the eserin, she turned purple and her bowels moved profusely and involuntarily. Respirations became shallow, the trachea, pharynx and larynx filled with mucus, and the pulse became imperceptible, even over the carotids. She remained unconscious for about twelve hours.

Treatment.—The following drugs were given hypodermically in divided doses: Atrophin, 1/10 grain; nitroglycerin, 1/30 grain; strychnia, 1/10 grain; brandy, a dram, and aromatic sulphuric acid, a dram; 1,200 c.c. of normal salt solution was also given subcutaneously around the breasts. She was surrounded with hot water bottles and given plenty of fresh air, the tongue being drawn forward with ordinary vulcellum forceps. She was catheterized every half-hour.

Recovery was probably due to the fact that she had received a small dose of atropin and morphin a short time before the eserin was given. Potter says that immense doses of eserin may be given without harmful effect if preceded by even minute doses of atropin, which is the physiologic antidote. The salt solution, no doubt, was of great benefit, because eserin is eliminated almost entirely through the urine. A mild enteritis followed, but this persisted for only a short time.

OBSTRUCTIVE JAUNDICE CAUSED BY A ROUND WORM IN THE COMMON BILE DUCT.

J. G. HILLEARY, M.D.
DUBOIS, PA.

The patient was a bright, well-developed boy, aged 10, who had never been confined to bed on account of sickness in his life. I was asked to see him on the eighth day of his illness. Besides being intensely jaundiced, his trunk and limbs were covered with large patches of urticaria, which caused him great annoyance from the burning and itching. Nausea and vomiting, with loss of appetite were present throughout the attack. The tongue was coated and the mouth dry. Bowels were constipated; stools clay colored, pasty and fetid. Temperature was normal; pulse 60. The lungs and heart were normal; the abdomen was normal except for pain and tenderness over the region of the gall bladder.

Having lately read an abstract of an article in the October number of the American Journal of the Medical Sciences, by W. Epstein, on the diagnostic significance of strangulation marks on round worms, and with the cause of the obstructive jaundice in this child not clear, coupled with a history of the passage of two round worms a few months previously, I made a probable diagnosis of a round worm in the common duct. Calomel and santonin were given, and in ten hours the worm was passed with complete relief of the symptoms. The worm showed a distinct strangulation mark two inches below the head.

As such markings are never found normally, I think it is safe to say the worm was the cause of all the trouble in this case.

SAFETY PIN SAFELY PASSED BY A CHILD OF ELEVEN MONTHS.

L. W. LITTIG, M.D.
IOWA CITY.

On October 19, Dr. W. D. Phillips, Victor, Iowa, consulted me regarding an 11-months-old baby who had accidentally swallowed an open safety pin, one and one-eighth inches in length. I was inclined to locate the pin with the *x*-ray and to at once remove, if seen in the stomach, but it was decided to wait for trouble and then to operate without delay. On October 24, a few hours less than five days after the pin had been swallowed, it was passed by the child. No inconvenience at all was suffered and no special treatment was given. The parents lived in the country, and did not bring the child for *x*-ray examination; hence, there was no opportunity to observe the progress of the pin through the intestine.

THE DIAGNOSIS AND PROGNOSIS OF PARALYSIS AGITANS.

The art of diagnosis requires a knowledge not only of the main types of a given disease, but also of its atypical forms, the so-called *formes frustes* of French writers. In some diseases easy of recognition in their typical form, atypical forms are common and difficult of recognition, and of no disease is this more true than of paralysis agitans. According to Erb's observations, paralysis agitans presents itself in an atypical form in about 20 per cent. of all cases, and Oppenheim believes that this estimate is too low rather than too high. Under such circumstances, a knowledge of the atypical forms of this disease is a necessity, as the condition is not uncommon.

Oppenheim[1] has recently expressed his views regarding this disease in a masterly paper in which he pays especial attention to the diagnosis of masked cases. Paralysis agitans without tremor, first described by Charcot in 1875, is stated to be quite common. In some instances the tremor is latent, and may be elicited by active movements, or by plunging the limb into cold water. In connection with tremor Oppenheim describes a procedure which produces what he calls false ankle clonus. The foot is strongly flexed dorsally and held in this position for some time; on release a rhythmical tremor may result, and is quite characteristic of paralysis agitans. In typical cases without tremor the diagnosis usually may be made on the general attitude of the patient, the muscular stiffness and the propulsion and retropulsion. The cases most difficult of diagnosis are those in which the disease is just beginning, and in which only one side or one limb is involved. Oppenheim states as a general proposition that a slowly developing stiffness and unwieldiness in the limbs of one side occurring in an old individual is generally paralysis agitans. The slowing of the movements in these cases and the stiffness usually begin first at the distal parts of the extremities, so that special attention must be devoted to the finger and toe signs if early diagnosis is to be made. In the fingers difficulty in flexing or extending the fingers one after another may be noted early, or abduction and adduction may be difficult. Changes in the toes are more difficult to detect, as the normal mobility of these structures varies a great deal. In unilateral cases, however, Frank has described a valuable diagnostic sign. This consists in the fact that any attempt to move the toes on the affected side results in movements in the toes of the non-affected side; the reverse is not the case. In some cases changes in the handwriting are of value in connection with other tests. Oppenheim lays stress on the tendency of these patients to write slowly and to construct much smaller letters than they formerly did.

Various early or premonitory signs are mentioned which may render diagnosis easier in doubtful cases. Rheumatoid pains, gastric disturbances, salivation and hyperidrosis are mentioned as not infrequently preceding paralysis agitans or accompanying the early stages. Bladder and rectal disturbances are rarely seen. Besides the ordinary difficulty of gait, the trouble in starting and stopping, an exaggeration of the former is occasionally seen. In some instances, the patient seems totally unable for some time to start walking, even when he desires to pass merely from one room to another. He stands as if rooted to the spot, and appears quite helpless. Oppenheim thinks that in these instances there is a strong psychic element at work.

So far as the prognosis of this disease is concerned, Oppenheim takes a much more optimistic view than formerly. He still states that he has never seen cure result in this condition, but he also states that under proper conditions he has seen the progress of the disease apparently delayed for a considerable period of time, and he has seen severe cases transformed into mild ones. The prognosis, of course, is most favorable in those cases in which the condition is recognized early, and the recognition of the atypical forms is necessary for this.

FOOTBALL AND ITS DANGERS.

Football is not as bad as the Fourth of July. In the first place it costs only ten to fifteen per cent. as many lives and fewer eyes; furthermore, the fun lasts three months instead of two or three days, so we get more per boy. Yet in spite of this evident innocuity, the popular protest against the game, as played at present, seems to be stronger and more general than ever before. Not that the game is waning in popularity, for as usual the attendance at the big championship games is limited to the number of people the grounds will hold, plus as many more as can get in. We hear a great deal about lessening the danger of football by making the game more open, and substituting end runs, trick plays and punting, for the steady hammering down the field a yard or two at a time, with a unanimous pile-up at each down. Interesting as the open game is to the spectator, the idea that the only real football is the line-bucking, bone-breaking game seems to have a firm hold. This was well illustrated by a recent championship game between two of the great universities of the Middle West. One coach had developed the open game to an unusual extent, not with any idea of "elevating the stage," but simply because his team was best adapted to that style of game. The team met another which limited its efforts to steady line plunging, and the open game won. The ball was on the opponent's side of the field the majority of the time, the line-plunging team made fewer yards than were made by the open game of the winner, and the team playing the open game did not have to take out a man for injuries during the entire game; and yet, almost unanimously the press and the public insisted that the defeated team played the better game, simply because it had gained more ground by line bucks than had its conqueror. The public verdict seems to be that five yards made by line bucking is worth more than ten yards made through open plays. While the public attitude is such it seems improbable that any reformation in football is near at hand.

---

[1] Deutsche Med. Woch., 1905, vol. xxxi, p. 1705.

From the standpoint of the educator, one of the greatest dangers of football is the degree to which it absorbs the student's interest. For the first two months of every school year the entire mass of students is concerned chiefly with the football prospects of the college team. As for the athlete himself—even if he is a *bona fide* student and not simply hired for his football ability—he is being crammed full of signals, new plays and "dope" of all varieties until there is little time or cephalic capacity left for anything else. In those colleges where a fair class-room standing is required by an unappreciative faculty, the football manager finds it necessary to provide tutors for his team in order to keep them on the eligible list. The whole student body is in such a state of excitement over football, to which the daily papers add in every possible way, that the many other interests that go to make up a normal college life are neglected hopelessly in the very beginning of the year's course.

Little good can be claimed for football on the grounds of physical training, either. The men on the teams are the very ones whom Nature has endowed superabundantly with physical capacity, but on them the physical director bends most of his energies, while the average student is left to get his physical development by yelling from the bleachers. The Rugby game, as Americanized, can never be a popular game in which all the members of a school can participate. To withstand the violence of hard tackling, and the crush of line plays, one must be in the best of training, and after a hard game the novice, if he lasts through, finds himself sore and weary for many days.

What is needed is a game that can be played by the majority of the students, without going through a prolonged course of training and preparation, and which is suitable for the coolness of the autumn and early winter days. Lacrosse has often been suggested as a substitute for football, and as a game that is both interesting to the spectator and full of good wholesome exercise it can not be surpassed. It might well form a part of our college sports and in a few colleges it does so, but there seems to be one obstacle to its general adoption—it requires a high degree of dexterity on the part of the player not soon acquired by a man not trained in athletics. Like baseball, it requires for satisfactory playing that it be taken up early in life and followed continuously, but still a certain degree of success and much pleasure may be obtained by the average student taking up the game for the first time after entering college.

There seems a much better prospect for the Association football game, and we welcome the effort that is now being made in several colleges to introduce it into their lists of sports. The use of the hands being eliminated, there are none of the dangers of tackling, and there are no mass plays. The ball is in sight always and in constant motion, features that appeal to the onlooker. Being a game that the most awkward novice can play after a fashion, and that still permits of high development of skill and of team play, it should offer opportunities to all classes of students. Such a game should be played within the circle of the individual college, between classes, departments, fraternities, dormitories and the other innumerable divisions of the student body. Without the strife incident to intercollegiate athletics there would be no more heard of professional coaches at large salaries, of professional players and other unacademic accusations. The game would then do far more for the physical welfare of the students as a whole, and there would be much less bitter feeling between sister institutions.

NEW YORK HEALTH BOARD FROM A GERMAN VIEWPOINT.

We have grown so accustomed to criticism from at home and abroad on our municipal government, we have come so to expect unfavorable comparisons between ourselves and other countries in this respect that we experience a shock of pleasurable surprise when we hear that a municipal department in one of our great cities is held up to general admiration. Still more gratifying is it to hear that the praise comes from Germany, from Berlin itself.

At a meeting of the Berliner Medizinische Gesellschaft,[1] Professor Wassermann, in a paper on "Municipal Hygiene," spoke of the Department of Health of Greater New York as a model to German cities, especially in the direction of public control of infectious diseases. Professor Wassermann pointed out the undeniable fact that the general practitioner has neither time nor authority sufficient to enable him to control the infectious diseases especially among poor, ignorant people. It is this function which the Department of Health of Greater New York has assumed without thereby encroaching on the rights of the physician. The two diseases which Wassermann chose to illustrate New York's methods are diphtheria and tuberculosis, and incidentally his comments throw light on the methods in use in German cities, which, apparently, are far behind New York and a few other cities in such matters. Although in many respects the methods in use in New York are common to our large cities, yet in completeness of detail they are unequalled, so far as we are aware, anywhere, and it may be worth while to outline them here, lest it should be said that foreigners do us more justice than we do ourselves.

---

[1] Cbl. f. Bakt. Ref. Aug. 28, 1905, p. 45.

Professor Wassermann describes, as he sees it, what occurs in New York when a physician visits an indigent case of tuberculosis. The first physician fills out a card which is sent to the Department of Health, stating the hygienic and social surroundings of the patient, and answering "yes" to the printed question whether or not he desires an inspector to visit the patient. The inspector—a physician employed exclusively in the control of tuberculosis—visits the patient, decides whether he may be left at home or must be sent to a hospital. In the former case, if he thinks necessary, he places him under the supervision of one of the department nurses for the tuberculous poor, who sees his directions as to care and precautions against infection are carried out. Meanwhile, elaborate statistics are in course of compilation, so that the department is gaining "an extraordinarily clear picture of the distribution of tuberculosis in the city, the existing sources of infection," etc. If a tuberculous patient dies at home, a placard is fixed on the door of the apartment stating in different languages (including Hebrew and Chinese) that tuberculosis is a communicable disease, and that the apartment must not be thrown open until it has been thoroughly disinfected.

The free examination of throat cultures for physicians, and the administration of antitoxin free to poor patients is so common a function of municipal health departments for us that we are surprised to find Professor Wassermann speaking of it as something extraordinary. In this respect New York does not differ from other cities, but we doubt whether many can boast of so careful and complete a system of supervision of diphtheria and other infectious diseases. As soon as a positive bacteriologic diagnosis of diphtheria has been made, the department notifies the principal of the school attended by the child. A list of quarantined patients, with their addresses, is furnished daily to schools, institutions, settlements, etc., together with the names and addresses of those just released from quarantine. A sanitary inspector, and if necessary, a department nurse, visits each quarantined case to make sure that the proper precautions are being observed. Disinfection is not performed nor the quarantined removed until two bacteriologic examinations of the throats of the patients and other members of the family have given negative results.

Professor Wassermann emphasizes New York's enormous task in combating disease among the thousands of ignorant immigrants from all parts of the world yearly landed in her midst. It is certainly a matter of pride that in the face of these difficulties she has shown herself able to perfect a system superior to that of cities which have not such enormous problems to solve.

TRANSPLANTATION OF ORGANS.

An interesting illustration of the application of clever surgical work to experimental physiology and pathology is the recent work of Carrel and Guthrie[1] of the University of Chicago. They have successfully removed a kidney from a dog and transplanted it into the neck of the same animal, uniting the renal artery with the carotid artery, the renal vein with the jugular, and the ureter with the esophagus. The circulation was not impeded by the formation of thrombi, and was completely re-established in a short time. In this new location the transplanted kidney secreted urine about five times as fast as the normal one. The constituents of the urine were the same, but in composition the chlorids were increased, while the organic sulphates, pigments and urea of the normal kidney were greater. The transplanted kidney examined some days following the operation was larger and darker in color than normally and the circulation distinctly increased. They claim this as the first successful transplantation of kidney on record.

They also successfully reversed the circulation in the thyroid gland of a dog by removing the gland and then replanting it, suturing the blood vessels in such a way that the blood entered the organ through the vein and left it through the artery. Forty-seven days later the replanted gland was normal, the only change being a slight increase in size.

This work is suggestive, not only from the standpoint of physiology, but particularly from that of therapeutics. It is in close relation to the work done by Cristiani[2] on transplantation of thyroids from one animal to another of the same species, and also to that of a different species. He showed that successful thyroid transplantation could be done with ease in animals of the same variety, but his results were not so good when transplantations were made from one animal to another of a different group, this depending on their relation in the animal scale. For instance, a graft from one class or family of animals to another always fails; from one order to another, as from dog to cat, usually fails; while from one variety to another, as between varieties of birds or of dogs, the result is usually successful. He did not unite the vessels, as do Carrel and Guthrie, and it is possible that with this improved technic the results may be much more successful.

Cristiani has promised experiments on transplantation of human thyroids into monkeys. This work is of great significance, because of the possibility of furnishing a permanent remedy for disease dependent on the loss of thyroid secretion, such as myxedema. This idea may be applied to other diseases also; thus in human diabetes one may consider the possibility of transplanting a portion of the pancreas from the anthropoid apes to the diabetic. It may even be possible at times to obtain human organs for this purpose, as in case of persons killed accidentally or dying suddenly from some other cause. The same question arises in connection with diseases of the suprarenal, though it appears that so far all attempts to transplant this organ have failed. Then there is the suggestion that eventually it may become possible to replace a permanently diseased kidney with a normal one. While many of these therapeutic possibilities are as yet more or less remote, the operative results obtained by Carrel and Guthrie show that a new way has been opened for the experimental study of many problems in glandular physiology.

---

THE JOURNAL OF BIOLOGICAL CHEMISTRY.

The development of medicine is along lines that were hardly dreamed of a quarter of a century ago; and not the least important of these is that which is known as biologic chemistry. Until now there has been no journal in the English language devoted to the subject. Under the circumstances, therefore—and this in spite of the fact that we have in this country ten times more medical journals than can be legitimately supported—we welcome a new one that has just appeared—the *Journal of Biological Chemistry*. It will be devoted to recording progress made in the biologic sciences, chemical in nature, and consequently that particular branch of science that now seems to promise so much for medicine. The editors are J. J. Abel of Baltimore and C. A. Herter of New York, and they will be assisted by an exceptional corps of collaborators. The *Journal of Biological Chemistry* should receive the encouragement of every physician who is interested in that branch of medicine.

PHYSICIANS' RESPONSIBILITY IN THE CRUSADE AGAINST PATENT MEDICINES.

As its share in the present concerted efforts to curb the nostrum evil, the main task of the medical profession of course must be to eliminate the objectionable features of the "ethical proprietary" trade. But it must also recognize its responsibility in the fight against the patent-medicine abuse. The lay publications that are exposing so thoroughly all the evils of the nostrum traffic can be depended on to continue their crusade, but they also must have medical support, if genuine reform is to be ensured. Further, in order to enjoy the benefit of a really free press or to secure pure food and drug laws, the newspapers must be constrained by public opinion to repudiate nostrum advertisements containing the enthralling "red clause." To this the medical societies should give immediate attention, as the time is at hand when advertising arrangements are made for the ensuing year. Resolutions do some good, and especially do they encourage the brave lay journals that are taking the lead in this reform. *Collier's Weekly* published November 18 a list of nine medical societies that have endorsed its efforts, and urged the societies to unite in some plan of action. The most effective method of persuading publishers to refuse contracts that throttle free speech is the appointment by local medical societies of committees to visit the publishers. The personnel of these committees should be adjusted to the object of bringing to bear the greatest possible pressure by persons of amiable dispositions, intimate acquaintance, respected standing and enlightened minds. These committees, armed with facts and knowledge of conditions as only medical men can be, will, if tactful, be almost irresistible, and should play a foremost part in abating a grave peril. Certainly the patent-medicine manufacturers will cry that we are interested from selfish motives, but this should not deter our action in the least degree. In the main, the public will discount that drowning plea of all monsters. At any rate, we should do our plain duty, being confident that such conduct will not long be misjudged. Only the other day a very prominent newspaper owner asked why physicians do not take the lead in informing the public of the real dangers of the patent-medicine traffic. He asked who were to inform the public and editors of newspapers of the physical harmfulness of the indiscriminate use of patent medicines if not physicians. It seems, then, that we are expected to act, and that other forces of reform are depending on us. This was emphasized by Mr. Bok's letter, which we published some months ago.[*] In addition to the passage of resolutions and the appointment of committees, our societies should aid in the wide distribution of the literature of the crusade, and should present the real reasons why patent medicines should not be used.

THE SUPERVISION OF HOSPITALS.

Following the lead of certain foreign critics who some little time since charged financial extravagance in the construction and the management of quasi-public hospitals in New York City, action has been urged recently to bring about some needed reforms. It would appear that the self-perpetuating lay boards of control of some of these hospitals are largely responsible for the evils of which complaint was made, and it is a natural consequence of excessive expense in building and management that such institutions must be seriously curtailed in usefulness to the general public. As adjuncts to charity they must necessarily be a failure to a very great extent. While we are apt to be suspicious of public control of such institutions in our large municipalities, a certain amount of it might be an excellent thing and would be only a reasonable offset to the exemption from taxation which such institutions enjoy. It is a rather striking coincidence that while the City and County Hospital at St. Paul was being held up—at a New York meeting of physicians—as a model of comparative excellence in the particulars in which the New York hospitals were open to criticism, the mayor of the twin city, Minneapolis, had just been calling attention to another hospital evil that is not peculiar to any one municipality. That is, the existence of private hospitals, conducted for gain or advertisement and uncontrolled by any special higher authority. It would appear from his remarks that special evils or scandals have brought such into prominent notice within a recent period in his city. That this is not a common occurrence is due to—

the fact that so many of these establishments carefully avoid any publicity. They are sometimes conducted by off-color physicians, sometimes by typical quacks and sometimes are respectably conducted by reputable medical men. In the latter case they generally have a corporate existence and a sort of quasi-public character, and, apart from a certain commercialism in their management, are unexceptionable. Not making pretenses to being charitable institutions their financial management is not open to public criticism. Nevertheless, if we are to insure against abuses, a certain public control and inspection is advisable and—if we are to reach all the disreputable "homes" "retreats," etc., which advertise in the daily press—is absolutely necessary. A public sanction or certificate of character based on rigid inspection laws would be a damage to no reputable institution. That there is a class of institutions requiring police surveillance can not be denied. They exist in every city, and the borderline between them and more respectable institutions may not be as distinct to the public as is desirable. While we do not accept as generally correct the allegation of the Minnesota mayor that reputable physicians connive at the unlawful practices of the shady practitioners, there are evil possibilities in the existence of these institutions that we should be on our guard against as a profession, and a reform in this regard should be supported if not originated among ourselves. If a layman can point out the evil of unregulated establishments of this kind it is an indication that public opinion is getting ripe for a reform.

LAVAGE FOR THE RELIEF OF VOMITING.

Vomiting results from such a diversity of causes that it is not to be expected that one measure will suffice for its relief under all conditions. Of course, the fundamental indication is to remove, when possible, the underlying or exciting factor, but not rarely the gravity of the symptom does not permit of delay, but demands speedy relief, either by palliation or by other means. One of the most distressing secondary phenomena of vomiting is the thirst resulting from the repeated loss of fluid. To compensate for this loss and to relieve this thirst, injection of large amounts of water into the bowel or the administration of small amounts by the mouth has been practiced, but neither of these methods always succeeds. An old and valuable household remedy is the free ingestion of water as hot as can be taken—with a pinch of salt, for flavor, if desired. It is popularly said that the water will either correct the stomach or will make vomiting easy and less unpleasant if it must continue. Attention is again called to the value of this procedure by Sir William H. Bennett,[1] who has adopted the suggestion made and put into practical effect by a patient, namely, the ingestion of ordinary cold or tepid water or other perfectly unirritating fluid in as large amounts as the patient desires. The vomiting may and is likely to persist, but the stomach is gradually washed out automatically and the patient is made more comfortable. A number of illustrative cases are reported, in some of which the vomiting itself seems to have been controlled.

---

Medical News

CALIFORNIA.

Bequest.—By the will of the late James C. King, Chicago, $10,000 is devised to a hospital in Pasadena, Cal., which the testator believed to be a worthy enterprise.

Hospital Incorporated.—The Oakland Central Hospital has been incorporated in Oakland by Drs. William D. Huntington, Oakland; T. A. Williamson; Edward R. Sill, Alameda; Robert T. Stratton, Alameda, and Chauncey H. Wilder, Alameda, with a capital stock of $75,000.

Will Not Change Meeting Place.—At a meeting of the San Bernardino Medical Society November 8 an attempt was made to change the by-laws so that Redlands should hereafter be the permanent headquarters of the society instead of San Bernardino. The motion, however, was voted down by the older members of the society with the assistance of the members from San Bernardino.

Charge Against Physician Dismissed.—Dr. W. Fred Stahl, Los Angeles, charged with illegal practice of medicine, was dismissed by the jury November 10. It was alleged that Dr. Stahl did not hold a license for practicing medicine from the state board of medical examiners, but the discharge of the prisoner was based, it is stated, on the contention of his attorney that he had applied three times to the state board to take the regular course, and that his application had been neglected each time.

Opposed to Lodge Practice.—Shasta County Medical Society has manifested its opposition to contract or lodge practice by adopting the following resolutions:

> Whereas, It is the sense of this body that contract society and lodge practice as now performed is detrimental, degrading and humiliating to the medical profession, therefore be it
>
> *Resolved*, By the Shasta County Medical Society in regular meeting assembled, that no member of Shasta County Medical Society be permitted to enter into contract relations with such society; and be it further
>
> *Resolved*, That no physician in the employ or such societies be eligible to membership in the Shasta County Medical Society. Be it further
>
> *Resolved*, That no member of the Shasta County Medical Society be permitted to consult with any physician following such contract practice.

Personal.—Dr. Reuben M. Bonar, Santa Rosa, has been appointed a member of the medical examining board for pensions in that city, vice Dr. Melville M. Shearer, deceased.——Dr. John H. Love, Ventura, was stricken with cerebral hemorrhage November 2.——Dr. Theodore D. Kellogg, Chino, was appointed medical superintendent of the San Bernardino County Hospital, vice Dr. Johann H. Meyer, removed, but resigned, and Dr. A. J. Aldridge has been appointed temporary medical superintendent.——Dr. John S. Hogshead, Laytonville, has been appointed physician of Mendocino County, vice Dr. William N. Moore, committed to the State Hospital for the Insane.——Dr. Solon Briggs, Los Angeles, has returned from the Atlantic Coast.——Dr. August Liliencrantz, Oakland, has resigned as a member of the board of health, and Dr. Charles A. Dukes has been appointed his successor.——Dr. Fred W. Colman has been appointed health officer of Lodi.——Dr. Spurgeon F. Priestly has been appointed health officer of Stockton.——Drs. Robert F. Rooney, Auburn, and Martin Schnabel, Newcastle, have been elected physicians of Placer County.——Dr. Jackson L. Martin has been made a member of the Fresno health board.——Dr. William J. Walsh has been appointed coroner of San Francisco County, vice Dr. Thomas B. W. Leland.——Dr. Granville MacGowan, Los Angeles, has been removed to his home after a successful operation for appendicitis.

DISTRICT OF COLUMBIA.

Milk Dealers Fined.—Three milk dealers who sold milk from cows which had been allowed to feed and drink from the sewer and marsh adjacent to the Smallpox Hospital, were arrested and tried. One was discharged and two were fined $20 each.

Health of the District.—During the week ended November 4, 118 deaths were reported, 64 white and 54 colored. During the same period 144 births occurred, 100 of which were white and 44 colored. There were 9 stillbirths, 3 white and 6 colored. At the close of the week there were under treatment 44 cases of diphtheria, 16 of scarlet fever, 160 of typhoid fever and 8 of smallpox.

ILLINOIS.

Cornerstone Laid.—The cornerstone of the John Warner Hospital, Clinton, was laid with simple formalities November 8.

Personal.—Dr. James H. Davis, Atwater, has returned after three years in Germany.

Diphtheria.—Reports to the State Board of Health show that cases of diphtheria are reported in 39 cities and towns, in 26 counties, from Cook County on the north to Alexander County on the south.

Epidemic Jaundice.—An epidemic of catarrhal jaundice, the cause and nature of which is obscure, is reported throughout the state, especially in Mount Pulaski and Rushville. The State Board of Health has instituted an investigation.

Valley Physicians Meet.—The eighty-first semi-annual meeting of the Fox River Valley Medical Association was held in Aurora, November 13. Dr. J. Forrest Bell, Elgin, was elected president, and Dr. Albert A. Fitts, Batavia, vice-president. The annual meeting will be held in Elgin in May.

Chicago.

Druggist's License Revoked.—The pharmacy license of Paul Vito, owner of two drug stores on the South Side, has been revoked by the State Board of Pharmacy on account of two convictions for the sale of cocain.

Bequests.—By the will of James C. King $10,000 is devised to the Chicago Home for Incurables and $20,000 to the Presbyterian Hospital.——The late Louis Schroeder has bequeathed $1,000 each to the Michael Reese Hospital, Alexian Brothers' Hospital and the German Hospital.

Personal.—Dr. Emma A. Hackett, resident physician at Hull House, is seriously ill from an infection of the hand due to an operation wound.——Dr. Engelbrecht Nelson has returned from abroad.——Dr. Albert H. Andrews has been elected professor of otology and rhino-laryngology in the Chicago Eye, Ear, Nose and Throat College.

Fraud Order Issued.—A fraud order against "Professor" Howell has been issued by the postoffice department. It is alleged that this individual, on receipt of the date of the birth of customers, sent to each a horoscope, telling him that he was suffering from a dangerous nervous disease. For the cure of this malady he sold a medicine for $4.80. Horoscopes of twelve varieties were distributed.

Urological Election.—The Chicago Urological Society, at its annual meeting, October 26, elected Dr. William L. Baum, president; Dr. Gustave Kolischer, vice-president, and Dr. J. Allen Patton, secretary. This society meets the last Thursday of each month excepting July, August and September. All regular practitioners in good standing in Cook County who are interested in medical or surgical urology are eligible to membership and welcomed at meetings.

Deaths of the Week.—During the week ended November 18, 510 deaths were reported, equivalent to an annual mortality rate of 13.35 per 1,000. The number of deaths was 31 greater than during the corresponding week of 1904, and 41 greater than for the preceding week of 1905. Pneumonia, for the first time this season, leads the death causes with 77, followed by consumption, with 70; nephritis, with 41; violence, including suicide, with 37; heart disease, with 36; cancer, with 31, and nervous diseases, with 21.

INDIANA.

Contagious Diseases.—Scarlet fever is reported at Windfall. Ten cases of typhoid fever are reported at Cambridge City.

Ten Instead of One.—In the Indiana news, November 18, it was announced that James Laboyteaux had given $1,000 for the erection of a hospital at Muncie, and that, if necessary, he would double his gift. Mr. Laboyteaux' original gift was $10,000, which he has promised to double, if necessary.

Personal.—Dr. Richard Schillinger has been elected mayor of Richmond.——Dr. Ebenezer P. Weist, Elwood, who soon leaves for Oklahoma, was given a dinner by the physicians of Newcastle November 10.——Dr. Isaac N. Cochran has been elected mayor of Delphi.——Dr. Oliver G. Mercer, Reelsville, has been appointed local surgeon of the Vandalia Road, vice Dr. Joseph F. Gillespie.

October Mortality and Morbidity.—The reports to the State Board of Health for October show that typhoid was the most prevalent disease and rheumatism the next most prevalent. Bronchitis, influenza and pneumonia prevailed extensively. On the whole, however, October was more healthful than the corresponding month last year, and also more healthful than September. The total number of deaths reported was 2,681, equivalent to an annual death rate of 11.9 per 1,000. Of these 426, or 16.9 per cent., were under 1 year of age, and 659, or 26.2 per cent., were 65 and over. Consumption deaths numbered 307; typhoid, 152; diphtheria, 78; scarlet fever, 5; whooping cough, 14; pneumonia, 138; diarrheal diseases, 167; cerebrospinal meningitis, 29; influenza, 4; puerperal fever, 9; cancer, 100, and violence, 155. Pneumonia showed a decided increase over September, and there were 30 more deaths from this disease than in the same month last year. Of the tuberculosis deaths 124 were males and 283 females. Of the males 22 were married in the age period of 18 to 40, in the prime of life, and they left 45 orphans under 12 years of age. Of the females 54 were in the age period of 18 to 40, in the prime of life, and left 111 orphans under 12 years of age. This disease invaded 271 families and tore the parents from 94 homes, making in all 156 orphans.

KENTUCKY.

Fraud Order Issued.—The postoffice department has issued a fraud order refusing the delivery of mail matter to the French Capsule Company, Covington, and to Dr. Ernest E. Schmidt of that city, who are alleged to be using the mails to promote the sale of a drug contrary to law.

Jefferson County Referee.—Dr. William H. Wathen, for a number of years county referee for the State Board of Health, has resigned, and Dr. William Bailey has been appointed in his stead. The executive committee, acting for the board, with Dr. Chester Mayer, temporary secretary, spread resolutions on its minutes expressing satisfaction at Dr. Wathen's work. Dr. Wathen, being dean of the Kentucky School of Medicine, felt it best that he should not continue to act in a dual capacity.

MARYLAND.

Personal.—Dr. Gordon T. Atkinson, Crisfield, has been re-elected comptroller of the state.——Dr. William Winder Goldsborough, Greensboro, has been elected a member of the state senate.

University Attendance.—There are 331 matriculants in attendance at the University of Maryland, of whom 99 are in the medical department, the remainder in the departments of pharmacy and dentistry.

Debt to be Paid.—The floating debt of $4,000 of the Western Maryland Hospital, Cumberland, will be wiped out, the state having appropriated $2,000 and an equal amount having been raised by private subscription.

State Examination.—The Board of Medical Examiners of Maryland will hold the regular examination December 13 to 16 at the hall of the Medical and Chirurgical Faculty of Maryland, 847 North Eutaw Street, Baltimore. Applications will not be received after December 7.

Society Election.—The Washington County Medical Society met last week and elected the following officers: President, Dr. Luther H. Keller, Hagerstown; vice-president, Dr. W. S. Richardson, Williamsport; secretary, Dr. Victor D. Miller, Jr., Hagerstown; treasurer, Dr. Hamilton K. Derr, Hagerstown, and censor, Dr. D. C. R. Miller, Mason and Dixon, Pa.

Hospital Report.—At the Springfield Hospital for the Insane there were 662 patients, of whom 388 are male and 274 female. The Edwin Warfield Cottage, named after the governor, will be ready for occupancy in about four weeks, and will accommodate about 60 additional patients. The managers are gradually providing artesian wells and thus doing away with the use of surface water at the institution.

Baltimore.

Bequests.—The late Dr. Charles C. Shippen left $5,000 each to St. Paul's Protestant Episcopal church and the Charity Organization Society.

Hospital Staff Changes.—Four of the resident physicians at the City Hospital have resigned: Drs. Robert Wriston, West Virginia; Alfred Brinham, Maryland; Edwin Bledsoe, Virginia, and George Berkheimer, Pennsylvania. Their places have been supplied by Drs. Lamar, Kentucky; Downey, Virginia; W. A. Glines, New York, and F. E. Knowles, New Jersey.

Mushroom Poison Antitoxin.—It is announced that Dr. W. W. Ford, instructor in bacteriology at the Johns Hopkins University, has discovered an antitoxin for mushroom poisoning. By boiling and filtering the poisonous species he obtained a toxin with which, by the same process that was used with the diphtheria antitoxin, he immunized small animals, thus obtaining a protective serum. The substance has not been tried yet in a human being.

St. Luke's Day Service.—A special service was held at Grace Protestant Episcopal church Sunday, November 19, for physicians, medical students and nurses. For many years such a service has been held in St. Paul's cathedral on St. Luke's Day, October 18. The sermon was preached by Bishop Court-land Whitehead of Pittsburg, chaplain of the St. Barnabas Guild for Nurses of America. After the sermon Dr. Howard A. Kelly addressed the audience.

Personal.—Dr. Henry Barton Jacobs returned to Baltimore November 13.——Dr. Randolph Winslow has been elected chairman of the section on clinical medicine and surgery, Medical and Chirurgical Faculty of Maryland, also consulting surgeon to the Hebrew Hospital.——Dr. Roland B. Whitridge will spend the winter in Europe.——Dr. Fairfax G. Wright, assistant medical superintendent of the University Hospital, has been ill with an infected wound of the hand.

MASSACHUSETTS.

Hospital Opened.—The remodeled Holyoke City Hospital was formally opened for inspection November 1.

Check for Hospital.—George E. Keith, Brockton, gave a check for $500 to the Brockton Hospital on the occasion of the dedication of the Douglas Surgical Pavilion and the Wales Memorial Ward, October 31.

Would Prohibit Animal Experimentation.—It is said that there will be introduced in the legislature this winter an "act to prohibit all experiments under any circumstances and for any purpose whatsoever, with or without an anesthetic, on dogs and cats." It is anticipated that physicians and the friends of science and progress and humanity in Massachusetts will be ready to oppose such legislation.

Superintendent of Leprosarium.—Dr. Louis Edmonds of Harwich, who has been associate medical examiner of Barnstable County, has resigned, in order to become superintendent of the new State Leper Colony, to be located on Penikese Island, fourteen miles from New Bedford. There are at present five lepers, two Chinese and three Portuguese, one of the latter being a woman, who will be moved with Dr. Edmonds from Harwich, where for a year he has had charge of them.

Tuberculosis Exhibition.—A free tuberculosis exhibit under the auspices of the State Board of Health is to be opened in Faneuil Hall, December 28. The project is the result of the efforts of the Boston Association for the Relief and Control of Tuberculosis and is backed by a state appropriation of $2,000. For ten days there will be lectures and demonstrations, both day and evening. Much literature in several different languages will be distributed and explained. Apparatus and demonstrations of methods for the prevention and cure of the disease will be presented in great detail and specific efforts will be made to popularize the exhibits. Reciprocal arrangements, too, have been made for the display of the entire New York City exhibition, whose date precedes this one in Boston.

Tufts College News.—Tufts College Medical School opened September 27 with a large entering class. There are now 379 students, of whom 109 are in the entering class. The following changes in the faculty have been made: Dr. Charles P. Thayer has retired as secretary because of ill health, and has been made emeritus professor of anatomy and has had bestowed on him a substantial pension; Dr. Frederick M. Briggs has been made secretary; Dr. Harry H. Germain has been appointed assistant professor of anatomy; Dr. Karl August Hoch, instructor in neuro-pathology, has resigned; Dr. Frederick C. Hollis, formerly of Yale Medical School, has been appointed instructor in medical chemistry; Drs. C. H. Staples and L. W. Strong, assistants in hematology; Dr. Edwin B. Neilson, assistant in gynecology; Dr. John D. Clark, instructor in anatomy; Dr. Theo. C. Beebe, Jr., assistant in surgery and assistant demonstrator of anatomy; Drs. John W. Lane, George McIntire, F. E. Haskins and Robert E. Andrews, assistant demonstrators in anatomy; Drs. Edison W. Brown and Leon S. Medalia, assistants in pathology and bacteriology, and Drs. Sidney C. Hardwick and Margaret E. Carley, assistants in physiology.

MICHIGAN.

Scarlet Fever Closes Schools.—Because of the prevalence of scarlet fever on the east side of the town, the school board of Elk Rapids has deemed it advisable to close the schools for a time. Rigid quarantine is being enforced.

Vote for Detention Hospital.—By a vote of 234 to 49 Ann Arbor has decided to raise $8.000 for a detention hospital for contagious diseases, to be built and equipped by the city, but to be maintained by the University of Michigan.

Personal.—Dr. Henry G. Glover, Jackson, has moved to Philadelphia, and Dr. H. T. Brown, Stockbridge, succeeds to his practice.——Dr. John B. Wright, Detroit, is ill with pneumonia at Grace Hospital.——Dr. Herbert M. Best, Ludington, has returned from the Pacific Coast and will practice in Grand Rapids.

Copper Range Changes.—Dr. Addison D. Aldrich, formerly of the Champion Mining Company, has been appointed physician at the Challenge mine, Hancock.——Dr. W. D. Whitten, formerly surgeon to the Quincy Mining Company, has been appointed physician at the Baltic mine.——Dr. William E. MacNamara, Brighton, has succeeded Dr. Cole at Redridge.——Dr. William K. West, Calumet, has been appointed chief surgeon of the Copper Range Mining Company and will reside at Painesdale.

Lockwood Hospital Report.—The annual report of the treasurer of Lockwood Hospital and Deaconess Home, Petoskey, for the fiscal year ended July 31, 1905, shows total receipts from all sources of $6,357.68, and total expenditure of $6,299.03, leaving a balance in hand of $858.65. The loss in operating the institution for the year 1903 was $2,393.10; for the year 1904, $949.63, and for the year 1905, $200.60. During the fiscal year 216 patients were admitted to the hospital, 201 discharged, 12 died and 16 remained in the hospital at the close of the year.

October Mortality.—There were 2,838 deaths reported for October, or about 200 fewer than in the preceding month. The death rate was 13.1 per 1,000 population, somewhat higher than the rate for October, 1904, which was 12.0. By ages there were 691 infants under 1 year, 219 children aged 1 to 4 years, and 747 deaths of elderly persons over 65. Important causes of death were as follows: Tuberculosis of the lungs, 190; typhoid fever, 102; diphtheria, 57; scarlet fever, 11; measles, 2; whooping cough, 13; pneumonia, 97; diarrhea and enteritis of infants, 357; cancer, 141; accidents and violence, 175. There was a very marked increase in the number of deaths from typhoid fever, and the number of deaths occurring from this cause, 102, was the largest reported for any month since the year 1900.

Wayne County Society on Vaccination.—Wayne County Medical Society, at its meeting October 1, put itself on record *against the action of the superintendent of schools of Detroit* in allowing children to enter school without having been vaccinated, by adopting the following resolutions:

Whereas, The superintendent of public schools of the city of Detroit on September 16 issued an order to the principals of all the public schools in this city directing them to admit pupils applying for admission to the public schools, whether they had been vaccinated or not; and,

Whereas, This action throws down all legal safeguards for protecting the public school children from the remarkably contagious disease, smallpox, and is directly contrary to a standing order of the school board still unrepealed; and

Whereas, Smallpox has been continually prevalent in the state of Michigan for the last four years; and

Whereas, The Supreme Court of the United States has held legal the right of the state to impose compulsory vaccination;

Resolved, That the Wayne County Medical Society considers this action on the part of the superintendent of Detroit's public schools an assumption of authority not belonging to his office, a dangerous and indefensible action and a serious menace to the city of Detroit.

NEW JERSEY.

Diphtheria.—The public schools of Winslow have been closed on account of an epidemic of diphtheria.——Several cases of diphtheria are reported from Elizabeth.

Personal.—Dr. William V. McKenzie, Metchuen, is seriously ill and it is feared that he will have to give up practice.——Dr. Calvin Anderson has been elected mayor of Madison.——Dr. Joseph H. North, Jr., has been elected mayor of Pleasantville.

Gifts to Hospitals.—The Entre Nous Club, Atlantic City, has given $5,000 to the Atlantic City Hospital for the endowment of a bed in that institution.——Mrs. Harvey E. Fisk has sent a check for $500 to the Monmouth Memorial Hospital and will also endow a bed.

To Start Medical Library.—For the purpose of organizing a medical library association for the use of physicians of Essex County and vicinity, a call was issued for a meeting in Newark November 18. The object of the proposed society is twofold: First, the establishment of a technical working library of practical value to physicians and which will receive the co-operation of the public library authorities in its maintenance and growth; and, second, the creation of an independent medical organization.

Verdict Set Aside.—The Supreme Court has rendered an opinion in which it sets aside the verdict obtained by George Lees, Plainfield, against Dr. Albert Wickman, Newark. In October, 1904, Lees sued for $20,000 for injuries alleged to have resulted from the improper application of a plaster jacket, and was given a verdict by a Somerset County jury for $780.20. At the trial it was shown by expert testimony that the injuries alleged could not have been the result of any treatment applied. The Supreme Court held that the verdict of the lower court was contrary to the evidence.

Italian Hospital Opened.—The new Hospital of the Immaculate Conception, Orange, was opened October 29 with due ceremony. The institution has now 25 beds and in a few days accommodation for 10 additional patients will be added. The medical staff consists of Drs. Thomas N. Gray, East Orange; Frank B. Lane, Orange; William O'Brien, West Orange; Antonio J. Amico, Newark; Ralph H. Hunt, East Orange; Frances E. Knowles, South Orange; W. D. Garrett, East Orange; M. W. Newcomb, East Orange; Carlo Martinetti, Orange; M. Herbert Simmons, Orange; Frank W. Lockwood, East Orange, and Charles W. Banks, East Orange.

NEW YORK.

Red Cross.—The first annual meeting of the New York state branch of the American Red Cross was held in New York City November 14. This society has 374 members. It is the intention of the state branch to organize subdivisions throughout the state. An interesting feature is the enrollment of doctors and nurses for emergency service. Drs. George E. Brewer, Samuel E. Lambert and John W. Brannan have consented to act as the advisory committee.

Charity Workers.—The New York State Conference of Charities and Corrections was in session in Carnegie Lyceum on November 14 and 15. Dr. Thomas Darlington, health commissioner of this city made an address at the opening session. In reviewing the important philanthropic events in the state during the past year he mentioned the passage of a special charities appropriation bill, instead of leaving the appropriations a part of the general bill, and the undertaking by the city of New York of establishing a tuberculosis sanitarium on Staten Island. The subject of the care and relief of needy families in their homes was discussed by Dr. Lee K. Frankel. He placed the total value of philanthropic agencies in New York state at $100,000.000 and the annual expenditure for the care of the poor and afflicted not less than $23,000,000. It was to be regretted that this large expenditure was not rather for the prevention of future ills than for the palliation of suffering already existing. A committee is looking into the matter of keeping accounts and the better financial administration of the hospitals. Dr. E. D. Shiner told what had been done by schools in the way of training atypical children and advocated a further development of the plan. The treatment of criminals, social betterment and the elimination of politics from charitable institutions was also discussed.

New York City.

Seagoers.—Dr. and Mrs. Calvin T. Adams sailed on the *Moltke* November 15.——Dr. L. P. Williamson, United States Navy, sailed on the *Minnetonka*, for London, November 18.

Italian Sanitarium.—City officials and leaders have interested themselves in the Harlem Italian Sanitarium, which was established a year ago by Dr. C. Atonna, Dr. F. Sanarelli and Mr. Caterain, and which is doing good work among the poor dwellers of the uptown Italian colony. At a recent benefit sufficient funds were raised to put the hospital on a permanent basis.

Good Health of the City.—The death rate of the city for the week ending November 11 was at the annual rate of 14.89 per 1,000. There are practically no contagious diseases at present. Among 600,000 school children there were only five deaths. Deaths from pneumonia have fallen to 60 and from tuberculosis to 74. Deaths from violence and suicide were most numerous.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending November 11, 335 cases of tuberculosis, with 160 deaths; 275 cases of diphtheria, with 22 deaths; 155 cases of measles, with 8 deaths; 105 cases of typhoid fever, with 12 deaths; 96 cases of scarlet fever, with 5 deaths; 13 cases of cerebrospinal meningitis, with 7 deaths, and 62 cases of chickenpox.

The Seaside Hospital.—The report of the society which supports this hospital shows that $90.000 has been raised during the past year, of which sum $3.000 remains in the bank after paying an indebtedness of $25.000 and paying the running expenses of the past year. During the past summer 33,661 mothers and children were cared for on the hospital boat, and 2,521 patients were admitted to the Seaside Hospital. It is the present object of the society to keep this institution open during the winter as a convalescent hospital; so there is great need of such an institution in or near the city. Dr. Ernest J. Lederle was elected one of the trustees.

OHIO.

Diphtheria.—Diphtheria is reported in North Amherst.——Bergholz is reported to have more than 20 cases of the disease.

Goes to Penitentiary.—"Dr." Charles Lewellyn, Youngstown, has been sentenced to imprisonment for one year in the penitentiary for impersonating a United States pension officer.

Violator of Law Fined.—W. W. Hodgkins, Toledo, pleaded guilty in the police court November 15 to practicing medicine without being registered, as being required by law, and was fined $50 and costs, but the fine was suspended until November 25 to give the defendant an opportunity to comply with the law.

Ill and Injured.—Dr. Phineas S. Conner, Cincinnati, is seriously ill from nervous trouble at the Good Samaritan Hospital.——Dr. William D. Hamilton, Columbus, was operated on for appendicitis in Chicago November 15.——Dr. Jerome Bland, Bucyrus, who has been seriously ill from cerebral hemorrhage, was taken to Hot Springs, Ark., for treatment November 14.

Farewell Banquets and Presentation.—The medical staff of the National Military Home, Dayton, gave a farewell banquet to Dr. D. Clark Huffman, formerly chief surgeon of that institution, October 31, at which he was presented with a loving cup.——On November 1 the officers of the home met and presented Dr. Huffman with a beautiful mantel clock.——The Guernsey County Medical Association gave a banquet at Cambridge, October 31, in honor of Dr. Frank M. Mitchell, president of the association, who left for his new home in Greeley, Colo., two weeks later.

Personal.—Dr. Charles C. Booth has been appointed local surgeon for the Lake Shore Road at Youngstown, vice Dr. Albert E. Warren, deceased.——Dr. Albert McClintock, New Moorefield, has returned from Raton, N. M.——Dr. Isaac C. Kiser, Fletcher, has been elected coroner of Miami County.——Dr. James A. Hubbell has been elected mayor of Quincy.——Dr. Robert Henderson, Urbana, has been elected a member of the board of public safety.——Dr. David N. Kinsman, Columbus, has been elected secretary of the State Board of Medical Examination and Registration, to succeed Dr. Frank Winders, resigned. This will necessitate Dr. Kinsman's resignation as chancellor of the Ohio Medical University.——Dr. William N. Bradford has been elected mayor of Cambridge.

PENNSYLVANIA.

Bequest.—By the will of the late Frank F. Risinger, the York Hospital will receive $5,000.

Personal.—Dr. J. Trechler Butz of Allentown, Pa., has been elected coroner of Lehigh County.

Antitoxin Stations Established.—Dr. Samuel G. Dixon, state commissioner of health, has established 500 stations throughout the state for the free distribution of antitoxin to the needy poor. The antitoxin can only be secured by personal application of the physician attending the case. Free antitoxin used by the state is made especially for it and bears a special label.

Philadelphia.

Northeast Branch to Organize.—It is announced in the roster of the county medical society that a meeting of medical men of the northeastern section of the city will be held November 27, to organize a northeast branch of the county society.

The Mütter Lecture.—The Mütter lecture for 1905 will be delivered in the hall of the College of Physicians, Thirteenth and Locust Streets, on Friday, December 1, at 8:30 p. m., by Dr. Aloysius O. J. Kelly on "Infections of the Biliary Tract."

Discharged.—Dr. Thomas B. Williams, who was arrested two weeks ago on the charge of having performed an illegal operation, has been discharged from custody, as the woman, her husband and the physician who was called in to attend her, failed to appear as witnesses.

Health Report.—The deaths from all causes in the city for the week numbered 407, which is a decrease of 31 from the number reported last week, and an increase of 6 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 6; whooping cough, 3; diphtheria, 11; tuberculosis, 47; cancer, 16; diabetes, 5; apoplexy, 25; heart disease, 37; acute respiratory disease, 63; enteritis, 18; Bright's disease, 32; suicide, 6; accidents, 26, and marasmus, 6. There were 253 cases of contagious disease, with 18 deaths, as compared with 251 cases and 18 deaths the preceding week.

Bequests.—By the will of the late Mrs. Nancy W. King of Doylestown, Pa., the Episcopal Hospital of Philadelphia receives $5.000 for the endowment of a free bed.——By the will of the late G. E. Gillingham the Pennsylvania Hospital receives $50.000; the Philadelphia Home for Incurables. $5.000; The Women's Medical College of Pennsylvania, in Philadelphia, $5.000, to be used for founding and maintaining a scholarship in said college; the Hospital of the Good Shepherd in Rosemont, Pa., $5,000 for founding and maintaining a free bed and other purposes, in the name of his deceased wife, Clara D. Gillingham; the Bryn Mawr Hospital, $5,000 for founding and maintaining a free bed in the name of his deceased wife, Clara D. Gillingham; the Maternity Hospital of Philadelphia, $5,000, and the Charity Hospital of Norristown, Pa., $5,000.

VIRGINIA.

Want Tax Abolished.—The Richmond Academy of Medicine has appointed a committee to try to have the city license tax abolished; a similar work will be pushed in the legislature in regard to the state license.

City Bacteriologist.—Richmond has just passed an ordinance creating the office and defining the duties of a city bacteriologist. The salary is $900 per year and the position is filled by election by the members of the board of health.

Physicians Raise Fees.—The Norfolk Medical Society has decided that calls responded to between 9 p. m. and 7 a. m. are to be considered night calls, and such visits shall be charged for at the rate of $5. It was considered wise to bring this matter before the public through the daily press.

Establishment of a Tuberculosis Sanitarium.—At the invitation of Dr. William F. Drewry, superintendent of the Central State Hospital, Petersburg, a number of physicians from different sections of the state met in Petersburg. The treatment of tuberculosis was discussed and the proposition to establish a sanitarium for this disease at Ironville, Bedford County, was considered. A considerable tract of land has already been secured, some cottages erected and a few patients are now under treatment.

GENERAL.

Yellow Fever in Havana.—The health officials of Havana, Drs. Finlay and Delgado, have officially notified the United States Public Health and Marine-Hospital Service of the presence of five cases of yellow fever and of several suspects in that city.

Wabash Surgeons' Association.—At the meeting of the Wabash Railroad Surgeons' Association, November 10, Dr. C. B. Powell, Albia, Iowa, was elected president, and Dr. Christian B. Stemen, Fort Wayne, was re-elected secretary, a position which he has held for the last twenty-four years.

College Association to Meet.—The annual meeting of the Southern Medical College Association will be held in one of the parlors of the Seelbach Hotel, Louisville, Ky., at 10 a. m., Monday, December 11, which is the day preceding the meeting of the Southern Surgical and Gynecological Association. The secretary is Dr. G. C. Savage, Nashville, Tenn.

Yellow Fever Subsides.—Pensacola, on November 12, reported that there was not a case of yellow fever under treatment, but a new one was reported the next day. Florida quarantines were removed on November 19.——Texas alone maintains quarantine, except that there is general quarantine against Havana.——Texas did not participate in the quarantine conference.——New Orleans, on November 11, had two cases under treatment and no new cases reported for the previous four days.——In Louisiana, outside New Orleans, there remain only some half-dozen cases in all.

Meeting of Western Bellevue Alumni.—The fifth annual meeting and dinner of the Western Alumni Association of the University and Bellevue Hospital Medical College was held at the Sherman House, Chicago, November 10. The president, Dr. Charles C. Hunt, Dixon, Ill., acted as toastmaster. The following officers were elected: President, Dr. John M. Ristine, Cedar Rapids, Iowa; vice-presidents, Drs. Calvin M. Fitch, Chicago; James F. Percy, Galesburg, Ill., and Dr. Frederick W. Werner, Joliet, Ill.; secretary-treasurer, Dr. Willis O. Nance, Chicago, and executive committee, Drs. G. Frank Lydston, Chicago; Paul Caspers, Chicago; James F. Todd, Chicago; John W. Van Winkle, Chicago, and Charles C. Hunt, Dixon, Ill.

Ohio Valley Medical Association.—The Ohio Valley Medical Association met in Henderson November 8 and 9. The following officers were elected: Dr. Daniel M. Griffith, Owensboro, Ky., president; Drs. Brooks F. Beebe, Cincinnati, H. Preston Sights, Paducah, Ky., and Curran Pope, Louisville, vice-presidents, and Dr. Benjamin L. W. Floyd, Evansville, Ind., secretary and treasurer (re-elected). Louisville, Ky., was selected as the next place of meeting. The association appointed a committee to work up a sentiment in the different states in the Ohio Valley regarding the proper care and treatment of inebriates by the state, with Dr. Dudley S. Reynolds, Louisville, as chairman. A resolution was also adopted asking the Kentucky State Legislature to have a bust of Dr. Ephraim McDowell placed in the Capitol in Washington.

The Southern Quarantine Conference.—Following is the full text of the quarantine resolutions which were unanimously adopted by the conference of southern states, to which we referred last week:

QUARANTINE RESOLUTIONS.

> Whereas, The experience of recent years, and especially the experience of this year, have demonstrated beyond cavil that the house mosquito, known as the *Stegomyia fasciata*, is the sole known cause of yellow fever epidemics and have demonstrated the futility and nuisance of many antiquated methods of quarantine hitherto resorted to, and the wisdom and necessity, in the interest of the public health and the public business, of uniform regulations to prevent the importation into the United States of yellow fever and its spread from state to state in the unfortunate event of its introduction; now, therefore, be it
>
> *Resolved*, That we, delegates from Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, Missouri, Maryland, North Carolin [illegible] ennessee, Virginia and West Virginia, hereby [illegible] the Senate and House of Representatives in [illegible] to enact a law whereby coast maritime and [illegible] quarantine shall be placed exclusively under the control and jurisdiction of the United States Government, and that matters of interstate quarantine shall be placed under the control and jurisdiction of the United States Government, acting in co-operation with the several state boards of health.
>
> We, furthermore, respectfully request that congress shall make adequate appropriation to enforce and perfect the objects of this memorial and to stamp out as nearly as practicable the yellow fever-carrying mosquito in its breeding or living places in the United States, and by negotiating arrangements with the governments of Central and South America and the West India islands, in places where the said mosquito has its breeding places or exists in said countries.
>
> *Resolved*, second, That we urg [illegible] f the several southern states that they [illegible] lations as nearly as possible in accord and [illegible] enacted.
>
> We, furthermore, urge the gov [illegible] eral states with the above object in view specifically to call the attention of the legislatures of their respective states to the wisdom and policy of this course.

The Norfolk *Virginian-Pilot*, November 12, said editorially:

> The Southern Quarantine and Immigration Conference has in our opinion, acted wisely in adopting a resolution requesting congress to enact a law "whereby coast, maritime and national frontier quarantine shall be [illegible] the control and jurisdiction of the U [illegible]" and the *Virginian-Pilot*, for one, [illegible] suggested legislation will be speedily enacted.
>
> In our opinion, the South is the section of the country which will derive the most benefit from national control, and every southern representative, who has the best interests of his section and his country at heart, should not hesitate to declare in its favor.

The New Orleans *Democrat*, November 11, said:

> There can be no question whatever of the jurisdiction of the Federal Government in regard to interstate quarantine affairs, its absolute constitutional jurisdiction, and some day this will be recognized so fully by all that there will no longer be any objection to its assuming sole charge of them.

American Tuberculosis Exhibition.—This exhibition, as we announced two weeks ago, will be held in the American Museum of Natural History, New York City, November 27 to December 9, under the auspices of the National Association for the Study and Prevention of Tuberculosis and the Committee on the Prevention of Tuberculosis of the Charity Organization Society of New York City. Chief stress is to be laid on a popular presentation of the facts of the situation and the approved methods of prevention and cure. This will be done by charts, tables, photographs, plans, models and apparatus. The co-operation from sana [illegible] n the United States and Canada has been [illegible] and both public and private institutions from all parts of the country will be elaborately represented. A representative collection of material from the recent exposition in Paris will form an attractive feature. Models of various tents and buildings for open-air treatment will be given a prominent place. A series of public meetings has been arranged. On the opening night the principal address will be by Mr. Talcott Williams, of Philadelphia, while brief addresses will also be made by Mayor McClellan, of New York, by Dr. Darlington, commissioner of health, and by President Jesup, of the museum. Wednesday evening, November 29, at a special meeting devoted to tuberculosis and the trades, the principal address will be by Mr. Graham Taylor, Chicago, with short addresses by President Gompers, of the American Federation of Labor, and other well-known representatives of organized labor. Friday evening, December 1, at a special meeting for physicians, addresses will be made by Drs. Lawrence F. Flick, Philadelphia; W. A. Evans, Chicago; A. Jacobi, New York; Vincent Y. Bowditch, Boston, and others. Friday, December 8, at a meeting for the teachers of the public schools, Dr. S. A. Knopf, New York, will speak. The New York Board of Education is cordially aiding the movement and is officially urging the teachers to attend the meeting and exhibition. The committee is in receipt of numerous requests from other cities for the loan of the material. The National Association for the Study and

Prevention of Tuberculosis is also endeavoring to form one or more traveling exhibits on a smaller scale which may be packed in small compass and kept constantly on the move, being exhibited in towns and villages where it would be impossible to arrange for or to finance a large exhibition. A special exhibition of pathologic material has been installed, the nucleus of which is formed by contributions from the Phipps Institute in Philadelphia and the Laboratory at Saranac Lake. Sanatorium physicians are specially asked to meet on the afternoon of December 1. Further information may be obtained from Mr. Livingston Farrand, secretary, 105 East Twenty-second street, New York.

National Tuberculosis Association Nomenclature.—We publish below the report of the committee on nomenclature to the National Association for the Study and Prevention of Tuberculosis, presented at the annual meeting in Washington. The association is anxious to have the proposed system tested by physicians in sanatoria and hospitals in order that criticism based on experience may be received. The executive secretary of the association is Dr. Livingston Farrand, 105 East Twenty-second Street, New York City. The report recommends the use, with additions thereto, of Turban's scheme for a method of comparative statistics for pulmonary tuberculosis. This is now used by the International Association for the Prevention of Tuberculosis in Europe. Following is a translation, with some modifications, from *Tuberculosis*, the monthly publication of the Central International Bureau for the Prevention of Consumption, September, 1904 (Johann Ambrosius Barth, Leipsig).

TURBAN'S SCHEME.

1	Extent of disease in the lungs.	I II III	For exact definition see below.
2	How long consumptive?	3 months..	Period to date from the observation of the first clinical symptoms, e. g., stubborn coughing, hemoptysis, pleurisy, loss of flesh, etc.
3	General condition of the patient.	A.......... X..........	A = favorable. X = unfavorable.
4	Digestion......	B.......... Y..........	B = unimpaired. Y = impaired.
5	Pulse..........	....	The pulse is to be registered every morning and evening, the patient resting.
6	Temperature ..	F.......... f.......... t n..........	F = Maxima for the day over 101 F. f = Maxima for the day from 99 F. to 101 F. t n = normal temperature (mouth).
7	Tubercle bacilli.	+.......... 0..........	+ = tubercle bacilli present. 0 = tubercle bacilli absent.
8	Tuberculous complicat'ns	Larynx....	Name of the organ suffering from tuberculosis.
9	Other complications.	....	Name of the disease.
10	Result of treatment.	....	(Vide classification of results of treatment proposed by committee on nomenclature.)

DEFINITION OF THE EXTENT OF DISEASE IN LUNGS, ACCORDING TO TURBAN.

I. *Slight lesion* extending at most to the volume of one lobe or two half lobes.

II. Slight lesion extending further than I, but at most to the volume of two lobes; or severe lesion *extending* at most to the volume of one lobe.

III. All lesions which in extent of the parts affected exceed II.

By "slight lesion" we understand *disseminated* centers of disease which manifest themselves physically by slight dullness, by harsh, feeble, or broncho-vesicul[illegible] râles.

By "severe lesion" we mean [illegible] and excavation such as betray themselves [illegible]y tympanitic sounds, by very feeble broncho-vesicular, bronchial, or amphoric breathing, by râles of various kinds.

Purely pleuritic dullness, unless marked, is to be *left out of account*; if it is serious, the pleurisy must be specially mentioned under the head of "*tuberculous complications.*"

The volume of a single lobe is always regarded as equivalent to the volume of two half lobes, etc.

ADDITIONS BY THE COMMITTEE.

PROPOSED CLASSIFICATION OF CASES AND RESULTS OF TREATMENT IN PULMONARY TUBERCULOSIS, TO BE USED IN CONNECTION WITH TURBAN'S SCHEME.

Progressive: (Unimproved). All essential symptoms and signs unabated or *increased.*

Improved: Constitutional symptoms lessened or entirely absent; physical signs improved or *unchanged*; cough and expectoration with bacilli usually present.

Arrested: Absence of all constitutional symptoms; expectoration and bacilli *may* or *may* not be present; physical signs stationary or retrogressive; the *foregoing* conditions to have existed for at least two months. (The length of time mentioned is of course somewhat arbitrary, but is *intended* to cover the cases which frequently occur, where the patients leave a sanatorium for various reasons, contrary to advice, after a stay of a few weeks, although all active symptoms *may have* ceased completely soon after entrance.)

Apparently Cured: All *constitutional* symptoms and expectoration with bacilli absent for a period of three months; the *physical* signs to be *those of a healed* lesion.

Cured: All constitutional symptoms and expectoration with bacilli absent for a period of two years under *ordinary* conditions of life.

Incipien[illegible] [illegible]ght initial lesion in the form of infiltration [illegible] or a small part of one lobe. No tuberculou[illegible] [illegible]ight or no constitutional symptoms (particula[illegible] or intestinal disturbances or rapid loss of weight). Slight or no elevation of temperature or acceleration of pulse at any time during the twenty-four hours, especially after rest. Expectoration usually small in amount or absent. Tubercle bacilli may be present or absent.

Moderately Advanced: No marked impairment of function either local or constitutional. Localized consolidation moderate in extent with little or no evidence [illegible] [illegible]ssue; or disseminated fibroid deposits. No [illegible]

Far Advanced: Marke[illegible] [illegible]cal and constitutional. Localized [illegible]e; or disseminated areas of softening; or [illegible]

Acute Miliary Tuberculosis.

PLAN SUGGESTED BY THE COMMITTEE ON NOMENCLATURE FOR TABULATION OF CASES FOLLOWING TURBAN'S SCHEME.

Name.		Condition.	Amount of Involvement.	Duration of Disease.	General Condition.	Digestion.	Range of Pulse.	Max. Temp. for day. Deg.	T. B.*	Complications.	
										Non-tub.	Tub.
Mr. X..	On admissi'n	Advanced	II	3 mo.	Favorable.	Impaired.	76–100	100	+	Neg.	Neg.
	At discharge.	Arrested.	II	9 mo.	Favorable.	Unimpaired.	76	98.6	0		

* Absence or presence of tubercle bacilli to be *determined only* after repeated examinations while patient is under observation.

CANADA.

More Insanity in Montreal.—Insanity is said to be increasing in Montreal. In 1898 the commitments for insanity numbered 158; in 1900, 174; in 1904, 251; this year, 171 up to November 1.

Smallpox in Ontario.—Thirty cases of smallpox have developed in a township near Peterboro, Ont.——Five new cases of smallpox developed last week in Toronto. Eleven patients are now in the smallpox hospital.

Personal.—Dr. G. Forrest Weatherhead, assistant physician of the Protestant Hospital for the Insane at Verun, Quebec, has been given a medal by the Montreal branch of the Royal Canadian Humane Association, for heroism in life-saving.——Dr. A. J. Richer, Montreal, delivered a public lecture in Quebec, November 6, on the new outdoor treatment of tuberculosis.——Mr. Z. A. Lash, K.C., Toronto, has contributed $10,000 to the proposed new Toronto General Hospital. The total now subscribed is $989,000.——Dr. H. R. Duff, Kingston, Ont., has been appointed vice-chairman of the Kingston General Hospital.——Dr. C. J. Fagan, provincial medical officer of British Columbia, has returned to Victoria from a trip east.

Hospital News.—During October there were 10 patients in the Swiss Cottage Hospital, Toronto, with smallpox. Four were discharged cured during the month, and 6 remained at the end of the month.——About $15,000 has been subscribed in Hamilton, Ont., for the purpose of a consumption sanitarium for that city.——A by-law will be submitted to the citizens of Winnipeg to raise $150,000 to aid in additions to the Winnipeg General Hospital.——The Toronto Nursing-at-Home Mission has cared for 327 patients since the first of June. The seven nurses connected with this institution made 2,578 visits to these patients.——A new hospital, Miseriorde Hospital—will soon be completed at Edmonton, Alberta. The edifice will be four stories high and will cover an area of 100x50 feet.——St. Paul's Hospital, Montreal, the new contagious diseases hospital in connection with Notre Dame Hospital, was consecrated by Archbishop Bruchesi on October 29.——A conference is to be held between the board of trustees of Toronto General Hospital, the Ontario government and the representatives from the University of Toronto, at a nearby date. The present board of trustees, which consists of five, three appointed by the government, one by the subscribers and one—the mayor—by Toronto, will hand in their resignations. It is likely that a larger board will be appointed to administer the affairs of the new hospital which will shortly be erected.——A new staff has been organized recently in connection with St. Boniface Hospital, Winnipeg. A meeting was held October 19, when Hon. Dr. O'Donnell was elected president and Dr. J. McKenty, secretary. The staff consists of the following members: Consulting physicians, Drs. O'Donnell, J. R. Jones and William Rogers; consulting surgeons, Drs. England, McArthur, R. McKenzie; attending physicians, Drs. Lambert, Nicholas, McKenzie, Peatman; attending surgeons, Drs. Todd, McKenty, Lehman; attending physicians, children's ward, Drs. Davidson, Dubuc, Slater; infectious diseases, Drs. Devine, penny, Teney, Gardner, Howden; oculist, Dr. Good; pathologists, Drs. Bell, McLean and Turnbull. Heretofore this hospital has been an open institution.——The late Senator Fulford of Brockville, Ont., left $25,000 to the Brockville General Hospital.——The Dominion government will erect a new detention hospital at Quebec with accommodation for 300 to 400

FOREIGN.

Closure of Russian Universities.—The *St. Petersb. med. Wochft.* states that all the Russian universities are closed.

Plague at Zanzibar.—Bubonic plague is reported to be present in Zanzibar, but steamship lines are said to be taking both passengers and freight.

Bubonic Plague in China.—The United States consuls at Antung and at Niuchwang report that plague has appeared at these places and that there has been one death from the disease at Niuchwang.

Variola in Chili.—It is reported from Valparaiso that since the beginning of the recrudescence of variola in that city in January, 1905, 11,000 people have been stricken with the disease and over 5,000 deaths have occurred.

Cholera in Europe.—Scattered cases of cholera are reported here and there in Russia close to the western border. The mortality was 1 to 3 in the epidemic in Germany, while in Russia it seems to be 2 to 3.

Australasian Association for the Advancement of Science.—The next session of this association was to have been held in Adelaide in September, 1906, but it has been postponed till January, 1907, as September is not a convenient date for many of the members who are engaged in educational work.

Typhus Fever in Glasgow.—An outbreak of typhus occurred in a house intended to accommodate 4 or 5 individuals, but in which 9 persons were living. The health officer of the city calls attention to this case and urges the necessity of dealing severely with cases of overcrowding, as they are a menace to the health of the community.

Fee for Consultation by Telephone.—The Prussian medical chambers (Aerztekammer) have been discussing the question of the fee to charge when a physician is consulted over the telephone. The medical chamber in Pomerania has announced that the fee is the same for medical advice given over the telephone as when the patient comes to the physician's office. The other organizations will probably adopt the same rule.

Organization of the Profession in Germany.—We learn that the *Leipziger Verband,* to protect the economic interests of the members of the profession in Germany, now numbers 17,000. Great efforts are being made to enlist the recent graduates in the society as valuable material for the future. For this purpose an employment, exchange and information bureau has been opened at the central office, which is accomplishing good work.

A Medical Library for India.—A movement is said to be on foot among the officers of the Indian Medical Service to establish at a convenient center a circulating medical library. At present there is no such library in India which is of any practical use to medical men. At the medical colleges in the larger cities there are reference libraries, but these are not available to men throughout the empire. A model for such a library is that at Manila, for the use of United States employés in the Philippines.

Prizes Offered by the Mexican National Academy of Medicine.—Two prizes of $500 each are offered by the Academia Nacional de Medicina and published in its organ, the *Gaceta Medica de Mexico* for August 1. The subjects appointed are: "Early Diagnosis of Tuberculosis and Means to Prevent Its Spread" and "Study of Leprosy in Mexico." Articles must be written in Spanish and be received by the academy before Oct. 1, 1906. Address: Apartado postal num. 517, Mexico. The competing essays must be accompanied by the náme of the author in a sealed envelope.

Pure Food Bill in Victoria.—The pure food bill, recently introduced into the Victorian parliament, says the *Australasian Medical Gazette,* provides that no person shall sell beer which contains more than a hundredth part of a grain of arsenic per imperial gallon, or that contains any lead, copper, strychnin, cocculus indicus, picric acid, or any substance which is not a normal and proper constituent of beer or a necessary ingredient in its manufacture. In future it will be an offence to make or sell toys colored with varnish that contains arsenic or any other substance in a quantity exceeding that prescribed by regulation.

Cholera in India.—It is reported that the outbreak of cholera, which has been raging in Madras since last July, has at last shown signs of abating. The average death rate from cholera during August was over 50 a day, but the returns for September showed about 30 a day. The cause of the epidemic has been traced to the emigration depot in the north of the "Black Town." It was adjacent to this depot that an outbreak of plague occurred last year and that it was only by prompt and very energetic measures that the danger of the outbreak spreading to the whole city was averted. Naturally there has been an outcry for the removal of the depots beyond corporation limits.

Evening Surgical Demonstrations.—Professor Hochenegg of Vienna has inaugurated a series of weekly surgical evenings, free to physicians, when he will demonstrate various common operations. The first of these "evenings" attracted a crowded audience and aroused great interest. A lively discussion followed the presentation of two patients who had been treated by resection of a tuberculous ankle with Mosetig iodoform filling of the cavity. Certain physicians expressed fear of iodoform intoxication from the procedure and others of the dissemination of germs, claiming that the faultless healing of the wound does not necessarily imply that local and general recurrence is out of the question.

Importance of a Third Person at Consultations.—A dentist in Berlin was recently sentenced to three years in the penitentiary on account of the unsupported testimony of a young woman patient who had a slight fainting spell while he was attending to her teeth. She became pregnant and claimed that he must have committed a criminal assault on her during her unconsciousness. She testified that his clothing was disarranged when she regained consciousness. A correspondent writing from Berlin states that physicians there are becoming very scrupulous in regard to the presence of a third party in all their consultations, especially with young girls and even with men, as the frequency of homosexual practices has warned them to be on the alert.

The Medical Building at Brussels.—The official inauguration of the "Maison des Médecins," on the Grand' Place, in the heart of Brussels, occurred November 19. A number of prominent officials were present, as well as delegates from all the medical and scientific societies of the district. The building contains a large assembly hall and numerous lecture and committee rooms, with a well-equipped library of periodical literature. A number of medical and scientific societies have already engaged quarters for their meetings, and glass showcases have been installed and space on the walls rented for advertising purposes. The second floor has been set apart for a permanent exposition of everything connected with the installment of hospitals, operating rooms, disinfection apparatus, etc. The basement is given up to a restaurant.

Australian Health Society.—The annual meeting of the Australian Health Society was held on September 30 at Melbourne. The governor, Sir Reginald Talbot, presided. The annual report stated that during the year arrangements had been carried out for the amalgamation of the society with the Association for the Prevention and Cure of Tuberculosis. This association has been instrumental in arousing public attention to the need of concerted action for the prevention of consumption, and it is believed that the union of the two societies will further the spread of hygienic knowledge and promote the cause of sanitary progress. The annual examination of public school pupils in the subjects of health and temperance, conducted by the council with the co-operation of the education department, formed an important branch of the society's work.

Carnegie College of Hygiene.—The Carnegie College of Hygiene at Dunfermline was formally opened October 4. The course of study is very comprehensive. The college year is divided into three terms of twelve weeks each, and the work is divided into two sections—theoretical and practical—which, in turn, are subdivided. The theoretical includes human anatomy and physiology, personal and school hygiene, theory of movements and teaching, symptomatology in connection with remedial gymnastics and school hygiene, and voice production. The practical course includes (1) educational gymnastics—Ling's Swedish system, (2) remedial gymnastics and massage, students being allowed, under medical supervision, to treat cases; (3) methods of class teaching, students having charge, under supervision, of classes of all ages in the public schools and in the gymnasium; (4) games, dancing, and swimming.

Tuberculous Immigrants in New Zealand.—Dr. Mason, chief health officer of New Zealand, calls attention to the fact that of 190 patients with pulmonary tuberculosis treated at the Cambridge Sanatorium, 16 were stated to have come from other countries, and that most of them were unable to pay anything toward the cost of their maintenance. He is reported as saying that shipping companies are the natural enemies of the health department, and that the natural desire of the shipper to escape quarantine delays is the cause in nearly every instance of infectious diseases being introduced into a hitherto clean country. He maintains that if a strict examination were made at the port of departure of all persons proceeding to New Zealand to take up their residence, there would be no grounds of complaint against the health department on the score of their methods of dealing with consumptive immigrants.

Celebration of the Tercentenary of a British Physician: Sir Thomas Browne.—A portrait statue of Sir Thomas Browne was unveiled at Norwich with great ceremony on the three hundreth anniversary of his birth, October 19. Although he did not contribute anything to the science of medicine, yet his great works, "Religio Medici," "Christian Morals," "Vulgar Errors" and "Urn Burial," and the beauty of his character and public spirit have immortalized his name. Professors W. Osler and Clifford Allbutt were delegates to the celebration from Oxford, and Osler stated in the course of his address that he had visited Norwich thirty-three years ago as a pilgrim to the place hallowed by the memory of Sir Thomas Browne. He remarked further that there are three lessons to be learned from his life, all of value to the profession today: "First, we see in him a man who had an ideal education. He was thoroughly versed in the classics, and lived abroad for two years, thereby becoming a citizen of the whole world. The second important lesson from his life is that he presents a remarkable example in the medical profession of a man who mingled the waters of science with the oil of faith. The third lesson is that the perfect life may be led in a very simple, quiet way. Norwich was a small town in his day." The one blot on his memory was that he believed in witchcraft, and testified in the last trial of witches in England, the women being condemned.

Cholera in Europe.—Germany is dealing successfully with cholera as it is brought over the Russian border, but the outlook in Russia is very discouraging, as scattered cases are reported from a number of points along the frontiers and elsewhere. The congress of medical men summoned to Moscow last spring to discuss measures to protect the empire against invasion by cholera passed resolutions urging radical changes in the taxation, etc., which grind down the people, keeping them at the point of starvation and thus rendering them unable to cope with disease. The congress further went on record with the statements that the prevailing unrest was so great that attempts to arrest the spread of cholera would be likely to meet with opposition on the part of the peasants, and prove dangerous to life and limb of those engaged in prosecuting sanitary measures. Also that the return of troops from the seat of war is liable to spread disease, and if there should happen to be a grain shortage the outlook would be very threatening. The congress officially voted in favor of a national representative assembly which could deal with these and allied questions. The congress was denounced by the authorities as revolutionary, we remember, and its transactions were suppressed, but the czar has done what the congress demanded in regard to summoning a national assembly. The problems before it, however, take time to solve. and the danger from cholera is pressing.

Sanitary Regulation of Costumes, Libraries, Pawnbrokers, Etc.—The authorities in Bohemia have recently decreed that the clothing and bed linen of persons who have recovered or died from infectious diseases should be disinfected, and also the clothing and linen of persons who have been in contact with the convalescent or the deceased. Masks for the face are not allowed to be rented, and wigs must be revarnished inside before they can be rented to another party. All garments which come in contact with the body must be washed clean before they can be rented out again. Books and pieces of music in circulating libraries need not be disinfected before being given out, as no effectual means of disinfecting them has yet been found practicable. But a warning should be pasted in each book or piece of music cautioning against turning the pages with the moistened finger, and also suggesting the advisability of putting a paper cover on the book or piece of music before handling it. The warning notice should further request the holder of the book to notify the proprietor of the circulating library in case there is infectious disease at his house. In case of notice of infectious disease the proprietor should withdraw the books or music from circulation until after formaldehyd disinfection. The proprietors of large theaters are required to disinfect the costumes, especially all garments coming in contact with the body, used by the stock company. Pawnbrokers' establishments must be equipped with their own disinfecting plants.

Eighth French Congress of Internal Medicine.—The main addresses at this congress, which was held at Liège in September, were on "The Clinical Forms of Chronic Rheumatism," "Avoidance of Salt in the Diet in Nephritis," and "Secretions of the Pancreas." Widal outlined the treatment of nephritis by "dechloridation" as requiring first the removal from the organism of the salt and the edema encumbering it; when this has been accomplished, then allowing in the diet only enough salt to correspond to the degree of permeability of the patient's kidneys for the salt. At first all salt should be forbidden, but when the organism has once been freed from the excess of salt and fluid, then increasing amounts of salt should be permitted, always keeping below the strict tolerance of the patient. The "dechloridation" may be aided by diuretics; theobromin and its compounds are the most effectual dechloridizers. An ordinary diet with 2,600 calories contains about 1.5 gm. of salt. Comparative dosage of the salt ingested and eliminated will reveal at once the degree of permeability of the kidneys. Beco's experience has been that the use of diuretics to supplement abstention from salt is equally effectual whether the effusion is of renal or cardiac origin. His experimental research has demonstrated that certain diuretics act on the wall of the renal vessels, dilating them and thus augmenting the circulation through the kidney. Dechloridation treatment is one of the rare examples of a therapeutic progress logically deduced from progress in theorizing. The *Presse Médicale,* Nos. 78 and 82, contains the full text of the reports.

Ninth French Congress of Urology.—The French congress of urology always follows the congress of surgery at Paris, and this year it met October 5-7. Tumors of the bladder, prostatectomy and functional diagnosis of kidney disturbances were the main subjects treated. Rafin declared in regard to tumors of the bladder that surgical intervention for their removal should be within narrow limits. It is a trivial operation and the remote results are extremely satisfactory when the tumor is pedunculated or can be pedunculated, but when the tumor is infiltrated the immediate results of attempts to remove it are extremely grave and the outlook is serious. In 96 cases of partial cystectomy for epithelial cancer, there were 21 deaths at once, and in 25 cases the outcome is not known. In the remaining 50 cases, 5 of the patients were alive after three to six years, but 30 succumbed to recurrence and in 16 the outcome is not known. Total cystectomy has been done 30 times, with 17 operative deaths. Pawick's patient is the only one still surviving. Hagge's patient lived for five and a half years. The operative mortality from sarcoma has been 43.6 per cent. and rapid recurrence is the rule. The operative mortality for myoma has been 28.5 per cent. and recurrence is liable. Weinrich stated that Nitze had removed 101 papillomata by his intravesical technic, and 72 cases have been followed to date without a recurrence. There has been recurrence in 18 cases; the others have been lost to sight. Cathelin exhibited some new instruments to facilitate his technic of perineo-suprapubic prostatectomy. Several speakers urged that the fact of there being only one kidney should not deter from surgical intervention. One reported a case of severe hematuria with a single kidney cured by decapsulation. Another cured a patient in uremic coma by decapsulation of the remaining kidney after removal of the other kidney two years before on account of tuberculosis. One speaker reported clinical cures even in advanced stages of tuberculosis of the kidneys. In 3 such cases the nephrectomy was followed by the entire subsidence of all the lesions in the bladder and prostate.

French Congress of Surgery.—The eighteenth congress met at Paris during the first week in October, immediately after the first International Congress of Surgery. The subjects appointed for discussion were "Surgery of the Pancreas," "Reparative Surgery of the Face," and "Conservation in Treatment of Traumatisms of the Limbs." Nimier delivered the address on the last subject, emphasizing the fact that the modern surgeon should not only aim to preserve the injured parts by correcting the primitive lesions, applying the necessary bloodless measures, but he should also strive to restore function to the parts, with surgical intervention if necessary for this purpose from the very first, as soon as the diagnosis and the indications are established. Repair of the traumatic lesions is easily done, but functional repair requires persevering massage, mechanotherapy, hydrotherapy and electrotherapy. Massage has taken in surgery the place it deserves, but the other physical measures are still in a somewhat rudimentary condition. Hospitals should be better equipped for functional cures of traumatic lesions than is the case at present. Doyen reported the successful suture of a severed axillary vein. He used very fine, round needles, suturing at separate points, and fastening the stumps to the surrounding parts to prevent any traction on the suture. In case of complete destruction of the axillary vein, he suggested that the external jugular might be transplanted on the stump of the shoulder, anastomosing it with the cephalic vein. To facilitate the suture of a vein, he advises suction cleansing of the field with an aseptic tube connected with a suction pump. This aspirates every particle of blood, etc. Calot described a new method of treating congenital dislocation of the hip joint. He makes a very small incision, less than 2 cm. long, and introduces through this a special dilating instrument, with which, instead of cutting the stricture in the capsule, he stretches it. When the capsule is thus stretched, the dislocation can be easily reduced, as he has accomplished in two cases with excellent results. The discussion of surgery of the pancreas showed once more the difficulty of differentiating lesions in this organ. Garrè said that he was able to save only 3 out of 11 patients with acute purulent inflammation or infarcts in the pancreas.

Crusade Against Tuberculosis in the Argentine Republic.—Among the measures adopted by the Antituberculosis League of Argentina is the publication and distribution of 200,000 copies of a "catechism" with questions about tuberculosis, and the same number of copies of a circular with directions for its cure and prevention. These circulars are distributed to children in the schools and to the audiences at public gatherings and at religious services. Two large wall tablets have also been issued, which are hung up in factories, public halls, schools, etc. One gives the proportions of the mortality from various diseases in the sixteen largest cities of the country, the proportions being shown in colored sections of circles. In Corrientes the mortality from tuberculosis is considerably more than half the total mortality, and in all it has the "lion's share," except in the two hotbeds of malaria. The second placard has in display type "the Disease," "Contagion," and "Curability." The second column, "Contagion," gives illustrations of the bacilli, the diseased lung tissue, and of pocket and standard cuspidors. Under the heading of "Curability" are included the means of getting cured by life in the open air, plenty of light and air, food and rest. A list of the tuberculosis sanatoriums and dispensaries, existing or projected, is appended, the list concluding as follows: "Sanatoriums for children, none; country homes for convalescents, none; seaside sanatoriums for children, one, the Hospicio at Mar del Plato; capacity, 125 children." Another measure which has served to popularize the ideas in regard to prevention and cure of tuberculosis has been the printing of antituberculosis maxims on all the boxes of matches issued by the principal company. As 10,000,000 to 12,000,000 boxes are sold each month, this is regarded as a great aid in the propaganda. The isolation of the tuberculous is now accomplished in the public hospital at Buenos Ayres, as the curable applicants are sent to the public sanatorium and the incurable to the Muniz Hospital. The other hospitals have solved the problem of isolation by refusing tuberculous applicants altogether. An illustration of the placards is given in the last *Semana Medica*, with the address on the subject presented by E. R. Coni at the recent International Tuberculosis Congress.

LONDON LETTER.

The New Cancer Research Laboratories at the Middlesex Hospital.

Cancer research at the Middlesex Hospital may be said to have gone on for more than 150 years. Records of cases have been accumulated since 1747 and are now being investigated. The new cancer research laboratories have the advantage of receiving material from two different classes of cases—those seen in general hospitals and susceptible of amelioration by operation, and those seen in the infirmaries and progressing to a fatal end. The laboratories were opened in 1900, at the same time as the present cancer wing, which contains forty-nine beds for incurable cases. The first director of research was Dr. A. Foulerton and the present one is Dr. Lazarus-Barlow. Under the latter the facilities have been greatly extended. In 1900 the director had three assistants; now he has eight, including four trained paid assistants, two holders of research scholarships and two voluntary workers who are training for research. Each worker has a separate laboratory and there is still room for others. The laboratories are fitted with all the most recent apparatus for histologic, bacteriologic and biochemical work. There are also a workroom, where apparatus are constructed, altered or repaired; a preparation room, where the tissues, organs, etc., are hardened, embedded and cut; a library containing the most recent monographs on malignant disease and current periodical literature on the subject, and cold-storage rooms in the basement which are used for specimens. The specimens and material in all its forms are so well classified and catalogued that any case from the year 1747 onward may be investigated at short notice. Every member of the department undertakes at one time at least two pieces of work—one statistical, based on the accumulated data of years, and the other a piece of research. Annual reports are issued comprising not only the description of the researches, but also the pathologic findings in some 300 fresh cases of malignant disease.

Sir Frederick Treves on the Army Medical Service.

At a largely attended meeting of the Brighton and Sussex Medico-Chirurgical Society, Sir Frederick Treves delivered an address on the army medical service. He pointed out that the so-called hospital scandals of the Boer war five years ago led to an extremely violent attack on the army medical service, which was undeserved by a body of men who were endeavoring to make bricks without straw. Since that time the medical service has been reorganized, according to the advice of a commission of experts appointed by the government. The chief change made in the status of the army surgeon is that his promotion now depends on merit and not on seniority. He is sent to the Army Medical College for study before he advances any step. Any man who does unusually well at the examinations gets accelerated promotion. It is now possible for the army surgeon to qualify as a specialist and the number who have done is is extraordinary. When so employed special pay is given. The result is that the army is attracting the best men in the profession. The present field equipment, Sir Frederick thinks, is the best in the world. It leaves little to be desired; it is light, compact and elastic. The general result is that the army medical service is second to none in the world, possessing a corps of highly competent and most efficient medical officers, an up-to-date equipment, and a most carefully elaborated organization; but there are anomalies in the war office—the army medical department is under the control of an adjutant-general who is not a physician. In the Boer war the admissions to hospital were 746 per 1,000 for disease and only 34 for wounds. This meant that the great bulk of casualties were due to preventable disease. But the army doctor had practically no power in that direction. The casualties at the battle of Colenso were nothing to those caused by the men drinking the contaminated water of the Modder River when peacably crossing it on a perfectly calm day. The army surgeon should have a much freer hand than he has at present. Sir Frederick concluded by pointing out what appeared to him to be needed to make the army medical service as perfect as possible: 1, The director general should be the head of his department and be responsible for its efficiency and economical administration; 2, he should have direct access to the army council and to the secretary of state; 3, he should have control of the money voted for the medical service; 4, the service should remain as at present, under the supervision of the advisory board; 5, an efficient army medical reserve should be formed; 6, the combatant officer should have some knowledge of hygiene as applied to campaigning and barrack life, and a like knowledge of a still more elementary character should be possessed by the private soldier; 7, the army medical officer should be vested with such authority and provided with such personnel as would enable him to carry out those sanitary arrangements in the field which experience had proved to be essential to secure the minimum loss of life from disease.

The Evil of Street Noises: Town Clock Nuisance Abolished in Birmingham.

The unnecessary evil of some city noises is well illustrated by a letter written by a man who underwent an abdominal operation in Birmingham. He wrote to the lord mayor, asking him if the quarter-hours of the town clock could not be stopped every day from 10 p. m. to 8 a. m., and the hours muffled to half-tones, as the ear-splitting stridency of the notes greatly disturbed him during the night. The lord mayor declined to interfere on "the grounds that the clock is a public one and its consistent working is of the first importance to the inhabitants of the city." The *Lancet* discussed the question and thought that both from a humanitarian and a business standpoint the decision was wrong. A clock which clangs noisily at quarter-hour intervals throughout the night must be a serious drawback to the recovery of the sick within hearing of its sounds. Nor is the loud chiming of a clock by day and night necessary for business. Much of the din which prevails in large towns by day and by night is avoidable. This protest by the *Lancet* has been followed by the decision of the city council of Birmingham to adjust the automatic apparatus of the town clock so as to cut off the chiming mechanism between 7:30 p. m. and 5 a. m.

Professor Osler at Guy's Hospital.

A very enthusiastic welcome was given Professor Osler at Guy's Hospital, where he delivered an address to the Pupils' Physical Society on "The Life and Work of Sir Thomas Browne." He was welcomed by the venerable president of the society, Sir Samuel Wilks, and the members of the staff of the hospital. In commencing his address Professor Osler claimed from the audience the "customary indulgence which is always extended to the bibliomaniac." He said that he had long studied the works of Sir Thomas Browne and in proof of this he pointed to a large table in front of him covered with editions of that author's works in Latin, German, Dutch and French. Among these was a copy of "Urne Burial," which was stated to have belonged to one of the sons of Sir Thomas Browne. Of the "Religio Medici" Professor Osler said with some slight emphasis that it was given to the world by Browne before he was 30, and quoted the author's contention that the magnetic force of a man began to fail after that age. This, Professor Osler said, was a sufficiently serious reflection for certain advanced thinkers who at the present day considered that a man was fit to work up to 40. He was proceeding to say what would happen to a man after 40 when he was interrupted by loud cheers and laughter. He treated with sarcasm the statement attributed to him by the Canadian press that men past work should be anesthetized out of existence, and whenever he alluded to this topic he drew sympathetic cheers from his audience. The address was illustrated by lantern slides thrown on a screen. Great appreciation was evinced by the students when it was announced that Professor Osler had presented a complete edition of the works of Sir Thomas Browne to their society. The chairman, Dr. Frederick Taylor, in proposing a vote of thanks to Professor Osler, said that to all intents and purposes he was an Englishman and commented on the charm with which he had communicated the fruits of his own recreation, bibliography. In replying Dr. Osler spoke of the veneration he had always entertained for Guy's men and of the great debt he owed to his "revered teacher," Sir Samuel Wilks.

Increase of Lunacy in London.

The number of pauper lunatics in asylums, licensed houses, workhouses, and with relatives and friends, on Jan. 1, 1905, was 24,652, an increase of 704 on the figures for the corresponding date of 1904. The increase on the latter date on the number for 1903 was 996—the highest on record. The superintendents of the different asylums, in their reports, assign various causes for the amount of insanity which exists. Intemperance, worry and heredity are specified by the superintendent of the Banstead asylum. The medical superintendent of the Claybury asylum finds that alcohol is the exciting or predisposing cause of insanity in 33 per cent. of the males admitted, and in 18 per cent. of the females. At Colney Hatch hereditary influences were found in 23 per cent. of the cases and congenital defects in 7 per cent. In Hanwell 24 per cent. of the admissions were due to alcohol and 48 per cent. to heredity. Possibly the increase of insanity shown by the figures is more apparent than real, for there has been an increasing tendency of recent years to certify for asylum treatment cases of senile decay. The recoveries for the year 1904 show the following percentages: On the total admissions, 33.5; on the average number of patients resident, 7.6; on the total number under treatment, 6.25.

The Study of Tropical Medicine.

The winter session at the London School of Tropical Medicine was inaugurated by an address on "Scientific Research in Medicine," by Professor Nuttall. Since its opening, in October, 1889, the school has received 554 students, including 40 women graduates. For the present session 39 students have entered, the largest number on record. Professor Nuttall traced the great development of tropical medicine in recent years for which Lazear, Myers, Durron and Plehn and others had laid down their lives. He pointed out that medical research requires endowment and said that it is a grievous thing that in this country, where so much is done for charity, so pitiably little is done for the advancement of learning. The wealthy classes in this country ought, he thought, to imitate their brethren in America. In many institutions one man is expected to perform duties which in more enlightened Germany are allotted to two, three or more teachers, each provided with a living wage. Most teachers of science in Great Britain receive pittances of which few are sufficient and many totally inadequate.

Pharmacology

REPORT ON NOSTRUMS IN GERMANY.

Translated by Dr. Henry Leffmann, Philadelphia.

In a recent issue of the proceedings of the Dresden scientific society, "Isis," Dr. A. Beythein, director of the Dresden municipal laboratory, gives the results of examinations of some secret remedies sold in that neighborhood. The data are of value, because they are from trustworthy sources, and interesting as throwing light on the conditions in Germany. Some of the remedies are for domestic animals, but it seems not amiss to include these. As a positive identification, the German title is given with a free translation.

Einreibungsmittel fuer Staerken der Hautnerven.[1] Inunction for strengthening the cutaneous nerves. The advertisement stated that the preparation contained Iceland moss. None was found. The following ingredients were found in 100 c.c.: Alcohol, 22.24 grams; ammonia, 1.10 grams; fixed solids containing a carbonate, 1.55 grams. It was a solution of ammonia in dilute alcohol, with a little potassium carbonate and opodeldoc.

Spezial-Ambrosia. Special Ambrosia. This a greenish-yellow salve sold by a quack for aiding parturition. The price is 3.75 marks for a package weighing 125 grams (about $1.00 for 4 ounces). It was found to consist of lard, flavored with carroway oil.

Wurmkrautpulver. Wormwort powder. This was found to be composed of powdered tansy flowers.

Dr. Tschernich's Universal-Lungenkraut. Dr. Tschernich's Universal Lungwort. This was found to be a powder of the entire plant of *Galeopsis ochroleuca* (a member of the Labiatæ).

Brandwunden-Crême. Emulsion for Burns. This contained starch, glycerin, mineral oil, a plant-extract of undetermined source and a red coloring matter.

Salbe gegen Syphilis. Antisyphilitic Salve. This contained tallow, lard and beeswax.

Coza-pulver. Coza Powder. Coza is possibly a proprietary name. The preparation is extensively advertised as a remedy for the drink habit. It was found to contain baking soda, a small amount of some umbelliferous fruit and calamus.

Rippsche Heilsalbe. Ripp's healing salve. This was recommended for many skin diseases. It was found to contain turpentine, egg yolk, paraffin, beeswax, aluminum acetate, balsam of Peru, boric acid, salicylic acid, and an undetermined perfuming material.

Mittel gegen Fussschweiss. Remedy for sweating feet. This was found to be a 12 per cent. solution of formaldehyd.

Hygiensche Brilliantine Heliosa. This is the high-sounding title of a hair dye containing an ammoniacal solution of silver nitrate.

Bickmore's Wundkur fuer Pferde und Vieh. Bickmore's Gall Cure. This was found to be a mixture of vaselin, boric acid and alum, colored with ultramarine blue.

Heuschkel's Kolkodin. Kolkodin is probably a proprietary name. It is advertised as a cure for colic in horses. It is sold in two parts: one a white powder, the other a brownish liquid. The powder is a mixture of white arsenic (60 per cent.) and white sugar (40 per cent.). The liquid was a carminative tincture. (No dosage is mentioned in the report, but it is probable that the white powder is directed to be given in very small doses, a practice followed by some stablemen.)

Makrobion. This is a proprietary name of obvious derivation. It is sold as a promoter of longevity. It was found to contain common salt, diatomaceous earth, baking soda, Glauber's salt, and sodium phosphate.

Creating a Nostrum.

Advertisement is an inseparable part of the nostrum business. The demand for a nostrum is created by the shrewdly prepared and widely published declarations of the wily promoter. This is true whether one refers to the nostrum exploited to the laity or to the one which is so-called "strictly ethical," "for physicians' use only," or to the remedy which tries to exploit both the profession and the public. A piquant and spicy series of articles is now running in *Printers' Ink,* entitled "Forty Years an Advertising Agent," by Mr. George P. Rowell. At one time he did business with an advertiser in Halifax, N. S., who sold a medicine known as "Fellows' Hypophosphites." The success of this remedy was such that some shrewd business men bought the trademark, incorporated a company, retained the original owner as manager, stopped all advertising except in medical journals, and thereafter pushed the sale only among the medical profession. Mr. Rowell relates how the stock increased in value, and our readers are, of course, aware of the quantities of this preparation which are now sold because of the systematic pushing of the remedy through the medical press. Mr. Rowell goes on to relate how he began to realize the value of a trademark, and how much money there might be in the shrewd launching of a simple remedy for common ailments when well advertised and marketed under an attractive trademark name. Accordingly he sought some preparation of this kind and even advertised for a trademark which he might buy for this purpose. He received offers of remedies for moths, for ague, for spavin, etc., but none of them seemed to be what he wanted. He nearly bought Dr. Lyon's rights in his tooth preparations, but, at the last moment, Dr. Lyon begged off and the deal was not closed. While still searching for something which he could thus exploit, a medical student asked him why he did not use the rhubarb and soda compound which was a stock prescription at a certain hospital in New York City where the student was an interne. This, however, was a liquid, which made it unsuitable for the purpose. It was not for some time that Mr. Rowell learned from the student that it could be made in the form of tablets. He was much delighted to hear of this and felt that he had found the remedy which he wanted. Taking an attractive name was, of course, necessary for the preparation. It seems that the prescription contained rhubarb, ipecac, peppermint, aloes, nux vomica and strychnin. By taking the initial letters of these ingredients the name "Ripans" was made. This preparation was put on the market and vigorously pushed. The packages were gotten up in a convenient and attractive way for sale by the druggist. Mr. Rowell relates the careful way in which all details of advertisement and sale were worked out. His narrative may be taken as an illustration of the method by which many nostrums are originated. Some article which may be of more or less benefit when indicated is exploited as a cure-all, and by means of a catching name, meets a ready sale through the willingness of the public to accept the medical advice of one of whom they know nothing. In other words, if the shrewd promoter will provide the humbug and press the magic button of publicity, the people will do the rest.

---

[1] The original text reads "Hauptnerven" (chief or head nerves), but I think this is a misprint for "Hautnerven" and have so translated.

Alcohol Percentage in Patent Medicine.

Among the many articles that are appearing in the newspapers, and which evidently emanate from the Press Bureau of the Proprietary Association, is an article bearing the superscription, "Alcoholic Percentage of the Tincture and Drug Compounds of the Dispensary of the U. S. Pharmacopeia." It appears as a double column table, and purports to show that the preparations of the Pharmacopeia contain as much alcohol, or more, than do patent medicines. Here are some of the shining examples:

	Alcohol. per cent.	Dose.
Tincture aloes and myrrh......	70.5	½ teaspoonful.
Tincture asafetida............	94	30 drops— 1 teasp'ful.
Tincture nutgall	84.6	1 to 3 teaspoonfuls.
Tincture jalap	62.6	1 to 2 teaspoonfuls.
Tincture guaiac	94	1 to 3 teaspoonfuls.
Tincture myrrh	94	15 to 30 drops.
Tincture squill	70.5	10 to 40 drops.
Tincture sanguinaria..........	56.4	30 to 60 drops.
Tincture podophyllum	84.6	5 to 15 drops.
Tincture quassia	32.9	1 teaspoonful.

Admitting that doses given are correct, what is the inference? That any of these tinctures might be given in doses of half-wineglassful, which is the average of the ordinary patent medicine bitters of the peruna or Hostetter type?

A tippler may tickle his palate with any alcoholic liquor from Peoria "rot-gut," Kansas "boot-jack," "Jersey lightning" or "Mexican pulque," but how long would his gustatory nerves appreciate the tincture of asafetida or of guaiac, or his digestive system recuperate under the tincture of jalap, of podophyllum or of blood root?

To show the care taken in compiling the list, the following examples are taken at random:

Ammoniated tincture of ergot alc........	56.4	per cent.
Tincture ferric chlorid..................	94	per cent.
Camphorated tincture of opium.........	90.24	per cent.
Tincture serpentaria	61.1	per cent.
Tincture serpentaria rhizome...........	84.6	per cent.
Tincture sumbul	61.1	per cent.
Tincture sumbul root..................	84.6	per cent.

The alcoholic percentage in tincture ferric chlorid and camphorated tincture of opium is given as nearly double what it really is. Note also the distinction in serpentaria and its rhizome and sumbul and its root and the great difference in the alcoholic strength of the respective tinctures. The fact that the rhizome and root, respectively, constitute the drugs proves that the alcohol percentages accredited the two tinctures for each of the two drugs are purely fictitious and suggests that the whole exhibit is faked up from some old family medicine or receipt book. Most of the alleged preparations are of British origin not used in this country. The entire production is of a most illiterate character and suggests that the Proprietary Association Press Bureau has been victimized by some one.

The Abolition of Secret Remedies.

When the American Medical Association undertook its proper duty of enlightening physicians as to the true composition of proprietary medicines, the step was hailed with delight by the profession, while, of course, there arose mutterings of anger from the camp of the unscrupulous manufacturers. Gradually the opposition is getting out into the light, so that it becomes possible to see who feels pinched by this great forward movement of the organized medical profession. Pharmaceutical manufacturers who have nothing to conceal welcome the advent of the Council on Pharmacy and Chemistry; but, unfortunately, in the last few years manufacturing and even retail pharmacy has become permeated with a spirit of deceit. For this state of affairs the ready gullibility of many thoughtless physicians is much to blame. To give the profession the actual facts is the task allotted to the Council on Pharmacy and Chemistry. Already physicians have been informed in regard to the acetanilid compounds, and seldom has a more important piece of work been laid before the profession. It is interesting to note that few, indeed, of the medical journals have mentioned the report of the Council on Pharmacy and Chemistry on the acetanilid compounds, though it appeared in The Journal of the American Medical Association over three months ago. This state of affairs is deplorable, but it is drawing to its close. Through its own state journals and through The Journal of the A. M. A., the profession now has control of its means of publicity. The Council on Pharmacy and Chemistry will ascertain the truth about our drugs, and the profession's press will disseminate the knowledge. One of the greatest reform movements of our time is thus well under way. Every physician will eagerly watch the march of coming events.—*Ohio State Medical Journal.*

War Against Quackery.

According to the *British Medical Journal,* an Austrian society for the repression of quackery will be formally constituted at a meeting to be held in the rooms of the Medical Society of Vienna on November 11. The French Congress for the Prevention of Unqualified Practice of Medicine, which was postponed last year, will be held in Paris from April 30 to May 3, 1906, under the presidency of Professor Brouardel. All communications relative to the congress should be addressed to M. Levassort, 2, Place des Vosges, Paris.

Prohibition of Advertising of Certain Secret Remedies in Germany.

In 1903 the confederated states of Germany formulated a short list of secret medicines, advertisement of which was prohibited. Some manufacturers evaded the law by changing the names of their products. On this account suit was recently brought against two manufacturers, one in Prussia and one in Baden. The Prussian court decided that the prohibition applied to the advertised name, and, the name having been changed, the article could be advertised without conflicting with the regulations. The Baden court decided the contrary, claiming that the product, not the name, was prohibited, and that it was forbidden to advertise it under any name.

Clergymen and Testimonials.

A very prominent anti-saloon worker, a clergyman, lately said that in shame he was compelled to admit that he had run across indubitable proof that there are ministers of the gospel who receive pecuniary commissions from the makers of alcoholic nostrums whose wares they recommend!—*Journal of the Medical Society of New Jersey.*

Correspondence

Laws Regulating Practice—American Academy of Medicine.

EASTON, PA., Nov. 18, 1905.

To the Editor:—I regret that an error of statement has crept in the otherwise most excellent synopsis of the report on the Laws Regulating the Practice of Medicine, read by the undersigned at the meeting of the American Academy of Medicine, as found in your issue of Nov. 18, p. 1596. The last sentence, reading: "The report favored having osteopaths represented on state medical examining boards," has its foundation in the discussion of the report. The report made no reference to the personality of a board of examiners. Its contention was that the general law should provide a test for all who wish to practice medicine, under this or that vagary, whether osteopathy, psychopathy, or what not, instead of, as at present, permitting special legislation, or special exemption; that this test should be on certain foundation subjects, and a special and limited license be given, which fact must be noted in every public announcement of the licentiate. Who should conduct the examinations was not mentioned. One would rather infer that they were to be under the care of the board of examiners of the state, who should possess a full license to practice medicine, and thus exclude all partially fitted persons.

CHARLES MCINTIRE.

Pathology of Amebiasis—An Acknowledgement.

MANILA, P. I., October, 1905.

To the Editor:—In the hurry of completing our article on the "Pathology of Intestinal Amebiasis," Dr. Musgrave and I omitted to give credit to whom credit was due. A certain number of the cases on which our statistics were based were cases at the First Reserve Hospital, in which Dr. R. P. Strong had done the autopsies either alone or assisted by Dr. Musgrave. The omission of this recognition was entirely unpremeditated, and we wish to express our sincerest apologies. In case the paper has gone to print[1] will you please give our acknowledgement space on another page? PAUL G. WOOLLEY.

Priority in Splenic Blood Research.

OMAHA, Nov. 16, 1905.

To the Editor:—My attention has just been called to an error made in my paper, "Indications for the Removal of the Pathologic Spleen," in THE JOURNAL, Sept. 2, 1905. Through some inadvertence I stated that Arteage preceded Dr. Edward T. Williams (not Williamson), of Boston, in the demonstration of nucleated red blood corpuscles in animal spleens. I find that this was an error and that Dr. Williams deserves priority in this matter, having published articles in *American Medicine*, April 26, 1902, and Nov. 28, 1903, on this subject.

B. B. DAVIS.

A Hint for the Anesthetist.—When it is necessary for the anesthetist to hold the patient's jaw forward, he will obviate much subsequent soreness by exerting the pressure on only one side at a time.—*Medical Standard.*

Marriages

ISAAC LEDERMAN, M.D., to Miss Hallie Streng, both of Louisville, Ky., November 22.

JAMES A. DIBRELL, M.D., to Miss Lula Beal, both of Little Rock, Ark., November 22.

CHARLES FAY AMOS, M.D., to Miss Susie Wanzer of Mesopotamia, Ohio, November 8.

JACOB DANIEL BROOK, M.D., Grandville, Mich., to Miss Mary Vander Velde, September 20.

METHE E. TRACY, M.D., Spickards, Mo., and E. W. EWING, M.D., Modena, Mo., October 25.

JOSEPH H. HINES, M.D., Atlanta, Ga., to Miss Cecelia Lopez of Charleston, S. C., November 15.

MURRAY A. STURM, M.D., New York City, to Miss Flora Rice, at Philadelphia, November 15.

JOSEPH C. ROTH, M.D., Upper Sandusky, Ohio, to Miss Lillian Ley of Tiffin, Ohio, November 22.

FRANK E. CLOUGH, M.D., Alliance, Neb., to Miss Louise Handke of Evanston, Ill., November 14.

CHARLES W. FALL, M.D., Fowler, Ind., to Miss Jeannette Barnhart of Frankfort, Ind., November 1.

ELISHA LEWIS SENCINDIVER, M.D., to Miss Mary Flick Stewart, at Martinsburg, W. Va., November 15.

L. L. BANKSTON, M.D., Tunica, Miss., to Miss Mai Leslie of Alligator, Miss., at Memphis, Tenn., November 8.

HENRY HAROLD BROWN, M.D., Philadelphia, to Miss Antoinette Fay Zimmerman, at Baltimore, November 15.

WILLIAM LEE GANNAWAY, M.D., Greendale, Va., to Miss Willie Belle Pierce, at Roanoke, Va., November 16.

J. PRESTON SENCINDIVER, M.D., to Miss Mollie Blanche Macgill of Catonsville, Md., at Baltimore, November 15.

C. FONTAINE-MAURY LEIDY, M.D., Philadelphia, to Miss Margaret Howard Ridgley of Towson, Md., November 25.

NORMAN ELLIS SARTORIUS, M.D., Tangier, Va., to Miss Ella Frances Schoolfield, at Pocomoke City, Md., November 15.

Deaths

James Montgomery Holloway, M.D. Tulane University Medical Department, New Orleans, 1857, professor of surgery and clinical surgery, Kentucky University Medical Department; surgeon for the Broadway Infirmary and the City Hospital of Louisville; member and president of the Mississippi Valley Medical Association in 1882; member of the Kentucky State Medical Society, died at his home in Louisville, November 13, from interstitial nephritis after a long illness, aged 71. Dr. Holloway began the study of medicine in Mississippi under the preceptorship of Dr. Harwood of Claiborne County. His first hospital appointment was at Touro Infirmary, New Orleans. In 1860 he settled in Madison County, Miss., and practiced there until the outbreak of the Civil War, when he enlisted as a private in the Eighteenth Mississippi Infantry, C. S. A. Soon afterward he was appointed regimental surgeon and was then placed in charge of the hospital service at Richmond until the close of the war. He was in active practice in Louisville continuously from that time until his final illness. He held chairs in several of the medical colleges, the first being that of anatomy in the University of Louisville; later he became professor of physiology and medical jurisprudence in the same institution, and afterward professor of clinical and operative surgery in the Kentucky School of Medicine and in the Louisville Medical College. He was one of the organizers of the Hospital College of Medicine in 1874, resigning his position in the Louisville Medical College at this time. He was professor of surgery in this institution for eight years, resigning again to take up the same work in Louisville Medical College. In 1898 he resigned from both of these college positions, when he became one of the founders of the Kentucky University Medical Department and was made emeritus professor of surgery, a position which he held until his death. In 1885 the degree of M.A. was conferred on him by Center College. In 1902 he served as president of the Association of Surgeons of the Army and Navy of the Confederacy.

Daniel E. Nelson, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1882, of Chattanooga, Tenn., member and ex-president of the Chattanooga and Hamilton County Medical Society; member and ex-president of the Tennessee

---

[1] See JOURNAL A. M. A., Nov. 4, 1905, p. 1371.

State Medical Association; member of the American Medical Association and member of the House of Delegates of the same; a consistent and faithful attendant at all medical meetings; member of the staff of Erlanger Hospital, died at that institution November 9, two days after a fracture of the base of the skull, the result of a fall from his horse, aged 46. The local medical society, at a special meeting, adopted resolutions of regret, respect and appreciation.

Henry Hobart Maynard, M.D. Rush Medical College, Chicago, 1861, of Los Angeles, Cal.; assistant surgeon of the Eighteenth Iowa Volunteer Infantry, later surgeon of the Second Arkansas Volunteer Cavalry, and then chief surgeon of division during the Civil War; a member of the Medical Society of the State of California and the Los Angeles County Medical Society; superintendent of the Los Angeles County Hospital in 1886 and 1887, and professor of surgery in the College of Medicine of the University of Southern California until 1901, when he was made emeritus professor, died at Pacific Hospital, Los Angeles, November 4, from uremia, after an illness of a month, aged 69.

George Reed Morehouse, M.D. Jefferson Medical College, Philadelphia, 1850; a member of the American Medical Association, Philadelphia Philosophical Society and Philadelphia College of Physicians; a prolific medical writer and collaborator with Dr. S. Weir Mitchell, died at his home in Philadelphia, November 12, from nephritis, after an illness of two days, aged 76. At his funeral the following personal friends acted as pallbearers: Drs. S. Weir Mitchell, William W. Keen, Charles P. Turner, Henry C. Chapman, John H. Musser, J. Chalmers Da Costa, J. Coles Brick, and Persifor Frazer.

George N. Munsell, M.D. Harvard University Medical School, Boston, 1860, assistant surgeon of the Thirty-fifth Massachusetts Volunteer Infantry in the Civil War; in 1889 representative from the second district of his county; thirty-seven years a school committeeman; twenty-five years medical examiner of Barnstable County; some-time president of the county medical society; vice-president of the Massachusetts Medical Society, etc., died at his daughter's home in Hyannis, Mass., November 2, aged 69.

Alexander Tunstall, M.D. Bellevue Hospital Medical College, New York City, 1868, a veteran of the Civil War, in which he served as adjutant of the Sixth Virginia Infantry, Mahone's Brigade, C. S. A., died at his home in Norfolk, Va., November 10, after a lingering illness, aged 62. The Norfolk Medical Society, at a special meeting, adopted suitable resolutions and decided to attend the funeral in a body.

Rufus H. Bartlett, M.D. Rush Medical College, Chicago, 1879, a member of the American Medical Association; chief medical examiner of the Ætna Life Insurance Company in Chicago; a member of the Chicago Medical Society, Chicago Medicolegal Society, Chicago Pathological Society and Chicago Medical Examiners' Association, died at his home in Chicago, November 21, from typhoid fever, aged 50.

George William Larrick, M.D. University of Maryland School of Medicine, Baltimore, 1878, local surgeon of the Baltimore & Ohio Railroad; for many years a member of the Frederick County Board of Health and of the board of visitors to the Western State Hospital for the Insane at Staunton, died at his home in Middletown, Va., November 6, after two years of invalidism, aged 53.

Edwin Curtis Bidwell, M.D. Medical Institution of Yale College, New Haven, Conn., 1844; surgeon in the Union Army during the Civil War; for nearly forty years a practitioner of Vineland, N. J.; discoverer of the black-rot fungus which threatened to destroy the grape growing industry in 1879, died at his home in Vineland November 14, aged 84.

William C. Voight, M.D. University of California Medical Department, San Francisco, 1879, a member of the American Medical Association and of the Washington County (Minn.) Medical Society, one of the leading physicians of Stillwater, died at his home in that city, November 3, from cerebral hemorrhage, after an illness of one week, aged 58.

Charles Henry Langdon, M.D. College of Physicians and Surgeons in the City of New York, 1874, for twenty-eight years a member of the medical staff of the Hudson River State Hospital, a member of the American Medico-Psychological Society, County Society, died from exhaustion following a second operation for appendicitis, November 15, aged 47.

Eli M. Whitson, M.D. Cincinnati, 1873, a veteran of the Civil War; a member of the American Medical Association; a member and once president of the Grant County (Ind.) Medical Society, died from dysentery at his home in Jonesboro, Ind., November 7, after an illness of two days, aged 62.

Thomas W. Jones, M.D. Medical College of Ohio, Cincinnati, 1847, one of the organizers of the Ohio State Medical Society and for fourteen years treasurer and librarian of the organization; for twenty-eight years a resident of Columbus, Ohio, died at the home of his son in that city November 6, after a long illness, from senile debility, aged 83.

Frederick L. Meagley, M.D. Toledo (Ohio) Medical College, 1890, a member of the American Medical Association, formerly a practitioner of Findlay and Toledo, Ohio, but for two years past in charge of a hospital at Daytona, Fla., died at his home in that place, November 5, from tuberculosis, after a long illness, aged 35.

Fred Stewart Blachly, M.D. St. Louis College of Physicians and Surgeons, 1899, of Modena, Mo.; a member of the Medical Association of the State of Missouri and the Mercer County Medical Society, died at the Missouri Baptist Sanatorium, St. Louis, November 9, after an illness of three years, from paralysis, aged 38.

Joseph Veazey Wallace, M.D. University of Maryland School of Medicine, Baltimore, 1853, of Chesapeake City, Md.; a member of the Medical and Chirurgical Faculty of Maryland; some-time president of the Cecil County Medical Society, died at the home of his daughter, in Lewes, Del., November 16, aged 76.

Thomas Camille Giroux, M.D. New York University, New York City, 1869, *a veteran of the Civil War, attending surgeon* to the Eastern District Hospital, Brooklyn, for many years, died at his home in that city, November 3, from heart disease, after a long illness, aged 64.

John Hauenstein, M.D. Geneva (N. Y.) Medical College, 1844, for more than half a century a practitioner of Buffalo, N. Y.; in 1882 president of the Erie County Medical Society, died at his home in Buffalo, November 10, from senile debility, after an illness of two years, aged 84.

D. R. Bookwalter, M.D. Medical College of Ohio, Cincinnati, 1897, died at his home in Dayton, Ohio, November 14, from laryngeal tuberculosis, after an illness of several months. He was a member of the Montgomery County Medical Society and the Ohio State Medical Society.

Friedrich Karl Castelhun, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1852, a prominent German-American poet and practitioner of San Francisco, died at his home in that city, November 1, after an illness of almost eight months, aged 77.

Christopher Fawcett, M.D. University of Maryland School of Medicine, Baltimore, 1864, resident physician to the Union Protestant Infirmary for twenty-seven years; assistant surgeon United States Army 1864-1865, died at his home in Baltimore, November 11, aged 81.

Frank S. Hamlet, M.D. University of Vermont Medical Department, Burlington, 1892, a member of the American Medical Association, and a prominent practitioner of Gorham, Maine, was instantly killed by a fall from the roof of his house November 6, aged 41.

Michelborough Y. Cheatham, M.D. Medical College of Virginia, Richmond, 1872, superintendent of schools of Amelia County, Va., and for several years chairman of the county board of supervisors, died at his home in Amelia Courthouse, Va., November 9, aged 54.

Anthony M. Oldfield, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872, committed suicide by shooting himself through the head while despondent on account of ill-health, at his office in Harbor Beach, Mich., November 3, aged 65.

Harry L. Hall, M.D. Medical Department of the Western Reserve University, Cleveland, 1882, for a long time township physician, died at his home in Mansfield, Ohio, from cerebral hemorrhage, October 29, after an illness of only a few hours, aged 69.

Isaac S. Herbein, M.D. Jefferson Medical College, Philadelphia, 1865, twelve years a justice of the peace, died at his home in Strausstown, Pa., November 14, after a prolonged illness, from nervous exhaustion, aged 69.

Louis Henry Dorwin, M.D. Miami Medical College, Cincinnati, 1872, a member of the Darke County Medical Society, died at his home in Gettysburg, Ohio, from diabetes, November 5, after an illness of two years, aged 57.

George F. Kalb, M.D. University of Maryland School of Medicine, Baltimore, 1902, of Cardiff, Md., died at the home of his parents in Catonsville, Md., November 3, from tuberculosis, after a long illness, aged 24.

Swan Hanson, M.D. (Years of Practice, Illinois), 1888, for several years trustee and alderman of Moline, Ill., died at his home in that city, October 30, from cerebral hemorrhage, after an illness of three days, aged 84.

James G. Boardman, M.D. Rush Medical College, Chicago, 1865, coroner of Stark County, Ill., for many years, died at his home in Bradford, Ill., from pneumonia, October 29, after a short illness, aged 65.

William E. Smith, M.D. Toronto University Medical Faculty, 1863, for twenty-eight years surgeon of the Michigan Central Railroad at St. Thomas, Ont., died at his home in that place, November 8, aged 68.

Andrew Lindsay, M.D. Jefferson Medical College, Philadelphia, 1855, of Bryn Mawr, Pa., died suddenly from heart disease in the railway station at Ardmore, Pa., November 9, aged 76.

Warren C. McManus, M.D. Howard University Medical Department, Washington, D. C., 1889, died at his home in Edgerton, Wis., November 8, from pneumonia, after a short illness, aged 44.

Phineas Sanborn Conner, M.D. Medical College of Ohio, Cincinnati, 1902, of Cincinnati, died at the Seton Hospital in that city, from pneumonia, November 11, after a short illness, aged 28.

Paul Grossman, M.D. University of Breslau, Germany, 1870, of Omaha, formerly a surgeon in the German army, died at Dobbrikow, Germany, October 13, from diabetes, after a long illness.

Thomas Clarke, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1860, died suddenly at his home in St. Catherine's Ont., November 5, from cerebral hemorrhage, aged 75.

George W. Lupfer, M.D. College of Physicians and Surgeons, Baltimore, 1881, of Neff's Mills, Pa., died suddenly from cerebral hemorrhage near Petersburg, Pa., November 2, aged 49.

G. F. Theodore Hoffmann, M.D. Rush Medical College, Chicago, 1861, died at his home in Niles, Ill., November 2, from bronchial pneumonia, after an illness of six days, aged 85.

Charles F. Cookes, M.D. Starling Medical College, Columbus, Ohio, 1882, died at his home in Columbus, November 1, from nephritis, after an illness of more than a year, aged 55.

Denis Collins, M.D. New York University, New York City, 1880, died at his home in Chicago, November 10, from cerebral hemorrhage, after an illness of seven weeks, aged 49.

William Dederick, M.D. County License, Indiana, 1897, died at his home in Warsaw, Ind., October 28, from carcinoma of the liver, after an illness of two months, aged 64.

Charles Carroll Shippen, M.D. University of Maryland School of Medicine, Baltimore, 1879, died at his home in Baltimore, November 6, after a long illness, aged 49.

Charles V. Bogue, M.D. Rush Medical College, Chicago, 1884, died suddenly from rheumatism at his home in Newport, Vt., November 8, aged 51.

Sarah J. Coe, M.D. Michigan, 1878, died at her home in Wilkesbarre, Pa., November 4, from paralysis, after an illness of three years.

Benjamin Genung, M.D. Brooklyn, 1869, of Brewerton, N. Y., died at his home in Baltimore, November 7, after an illness of six months, aged 34.

William F. Forien, M.D. Baltimore Medical College, 1899, died at his home in Baltimore, after an illness of six months, aged 34.

Henry C. Wohlgemuth, M.D. Cincinnati, 1854, died at his home in Springfield, Ill., November 11, aged 83.

Mark F. Hamilton, M.D. Philadelphia, 1878, died at his home in Cambridge, Maine, November 5.

Death Abroad.

R. A. Koelliker, M.D., formerly professor of comparative anatomy, physiology and embryology at Würzburg, died November 3, aged 88. *His* great manual of histology was published in 1852, and has appeared in many editions and been translated into several languages. He issued a volume of reminiscences in 1899 which contained a list of 245 articles which he has published on anatomy, physiology and similar allied sciences, and to this might be added 43 theses written under his supervision by his pupils. Since then he has contributed other important works to science. He is called the "father of cellular physiology," and to him we owe much of our knowledge of the nucleus of the cell and of normal histology, and of physiology in general.

Book Notices

Technique du Traitement de la Luxation Congenitale de la Hanche. By Dr. F. Calot. Avec 206 figures dans la Texte et 5 Planches. Paper. Pp. 293. Paris: Libraires de l'Académie de Médecine, 1905.

Calot's work of 294 pages on the technic of treatment of congenital hip dislocation is profusely illustrated. It aims to present the technic in such a way that any practitioner can treat congenital dislocation of the hip joint without the necessity for referring the child to a specialist, if the child is seen between the ages of 2 and 5. Calot first describes the differentiation of the condition as the child begins to walk, and then tells how to prepare the joint as a preliminary to reduction, and then the various steps of the reduction. He then describes the various types of cases that are liable to be encountered, and the modifications of the technic for older children, bilateral luxation, etc., with histories of cases belonging to each type, profusely illustrated before, during and after treatment.

A Treatise on Diagnostic Methods of Examination. By H. Sahli. Edited with additions by F. P. Kinnicutt, M.D., and N. B. Potter, M.D. Authorized Translation from the Fourth Revised and Enlarged German Edition. Coth. Pp. 1008. Price, $6.50 net. Philadelphia: W. B. Saunders & Co., 1905.

Sahli's work on clinical diagnosis has long been known in Germany as an authoritative one. This excellent translation will surely be appreciated by English readers, for it is in every sense worthy and even of superior merit. Every topic is discussed from a broad point of view and the close relations of anatomy, physiology and pathology to clinical phenomena are clearly set forth. It is in no sense a mere compilation; it is permeated everywhere with the spirit of the clinical and laboratory expert who describes methods, technic and results that have been tested by his own ripe experience and his original investigations.

The plan of the work includes the examination of the various organs and systems of the body by the methods of inspection, palpation, percussion, auscultation, etc., with full descriptions of the aids to be derived from instruments of precision, from bacteriology, chemistry and physics. Special methods of examination as in neurology are given in detail. All the chapters are excellent, though it seems to us that those on the examination of the heart, the stomach contents, the urine and the nervous system are exceptionally fine. The value of exploratory puncture as a diagnostic aid and its technic is admirably set forth; the chapter on cryoscopy is an up-to-date monograph; the description of the butyrometric method of examining the functions of the stomach by the method of Sahli and Seiler is a condensed statement of the results of valuable original research. Several tables are found that will prove of great service for reference; we may mention the one showing the substances that respond to the copper and the bismuth tests for sugar in the urine, the one showing the reactions of proteid bodies in the urine, and several in the chapter on the nervous system, as well as the outlines in the appendix, for the examination of the blood, nervous system, digestion, angina, etc.

We are somewhat surprised to find that the dimethylamidoazobenzol test for free HCl in the stomach had to be inserted by the editors. We feel that the so-called Hay's test (with sulphur) for bile in the urine deserves mention, as does peroxid of hydrogen as an oxidizing agent that may be used in some of the tests for indican or for blood in the urine. Bradycardia might perhaps be discussed more fully and esophagoscopy is not given the attention it merits. Only rarely do we find directions loosely given, e. g., those for making Lieben's iodoform test for acetone in the urine. "Some potassium hydrate and Lugol's solution are added to the urine, or better to its distillate" (p. 495). "Some" is altogether too inexact here. Pavy's method for the quantitative examination for sugar in the urine is rather severely condemned. We are pleased to note, however, that Sahli has recently (*Deutsche med. Woch.*, Sept. 7, 1905), reversed this decision and advocates Pavy's method with some slight modification. The value of the Roentgen rays in diagnosis is, we believe, underestimated by Sahli. He omits their consideration, he tells us in the preface, for the reason that he does not consider himself a competent radiologist capable of teaching others, and also because the x-ray examination can only be made by a limited number of practitioners who, in order to be able to do so, must go through a special training; his book is intended for the general education of the physician. The editors have aimed to supply this lack in the book by a few illustrations showing the results of x-ray examinations. Most of them are so poorly executed as to be of little value. Occasionally there is a figure that illustrates something to which no reference is made in the text. This is true of Plate 12—or else we have overlooked in the text and index the reference to Kernig's sign. In general the insertions by the editors are timely and appropriate, e. g., the notes concerning uncinariasis, blood-pressure instruments, etc. Not a few typographical errors are to be found. Thus a boric acid stone in the kidney is spoken of on p. 732, where evidently uric acid is meant.

While these few minor criticisms seem to us justified as we have glanced through the volume, we have no hesitation in recommending Sahli's work on diagnosis to student or practitioner. We believe it has no superior in any language.

THE ACCESSORY SINUSES OF THE NOSE and Their Relations to [illegible] Illustrated by Fifteen Colored Plates by G. [illegible] by R. Patterson, M.D., M.R.C.P., Atlas. Price. [illegible] : W. T. Keener & Co.

The superb drawings of this magnificent atlas enable one to acquire clear and definite mental images of the parts considered, whose labyrinthine intricacy is confusing even to the expert anatomist. In making the objects for the illustrations the mucous membrane lining the sinuses was hardened and stiffened by a formalin process, so that the soft parts formed a perfect cast of the cavities to which they adhered. This enabled Killian to show the accessory sinuses in an entirely new and striking way, that is, not as hollows in the ethmoid, sphenoid, frontal and superior maxillary bones, but as a cast of these hollows, a manner of display that produces singularly lucid mental pictures of the shape and location of the accessory sinuses of the nose. A great many fresh bodies were needed to complete the work, which extended over three years.

The artistic finish of the drawings is perfect and their clearness makes them readily understood. The anatomic relations of the sinuses to the orbit, the cranial cavity and the brain are made plain by fenestra made in the bones of the face, nasal fossæ and skull after removal of the outer soft parts. In this way, views of the sinuses through the outer nasal wall, and of the brain as it lies above the frontal sinuses, the ethmoidal cells and the sphenoidal sinuses are portrayed in a manner that is a revelation to those who have long wished to have a clear picture of these parts in their minds. Dissections of those parts of the brain liable to be involved in cerebral abscess due to sinus disease are also shown with their relations to the accessory cavities of the nose, and the optic nerves, the internal carotid arteries, the cavernous sinuses and the nerves of ocular motion are shown as they lie above the sphenoidal sinuses. The intricate grouping of the ethmoidal cells and Killian's new nomenclature of these cavities are made plain.

The text is full and clearly explains the plates, with the lessons to be drawn from their study; a great advantage over most atlases where the beholder is left to hunt out for himself the nature of the structures displayed in scantily lettered drawings without explanatory text; in fact, even without the plates the reading matter of Killian's atlas would give a very good conception of the subject and make an important monograph.

The practical side of the subject is dwelt on, especially in reference to Killian's great work in the surgery of the sinuses and to those wishing to perform his classic radical operation for empyema of the frontal sinus this atlas will be a great aid. The accessibility of cerebral abscess resulting from sinusitis is also thoroughly gone into. The neurologist, oculist and general surgeon will find the book of great value in the study of diagnostic problems, for it explains the difficult relations of the brain, cranial nerves and orbit to the air-containing cavities grouped about the nasal fossæ with a thoroughness and clearness that will save much time and study. The drawings are made from individual cadavers and, therefore, unavoidably contain special features pertaining to the individual body used. These moderate variations from what is typical, however, do not materially take from the value of the work, and it is preferable to have an exact picture of the parts as seen in nature in one subject than to have a composite drawing attempting to show a combination of the usual features in a number, for such drawings are apt to be schematic.

The translation has been done with great care and the difficult problem has been solved of selecting customary anatomic terms in use in Great Britain and America to correspond with the many different ones employed in Germany.

BIOGRAPHIC CLINICS. Vol. III. Essays Concerning the Influence of Visual Function, Pathologic and Physiologic, on the Health of Patients. By G. M. Gould, M.D. Cloth. Pp. 516. Price, $1.00 net. Philadelphia: P. Blakiston's Son & Co., 1905.

In the third volume of "Biographic Clinics" Dr. Gould continues in a characteristically vigorous manner his striking essays on the influence of the visual function on health. He discusses minutely the long invalidism of John Addington Symonds, and Taine, the celebrated French philosopher, historian and critic. As in his previous volumes, Dr. Gould sets forth the prominent rôle of uncorrected eyestrain in their life-tragedies of persistent and seemingly inexplicable physical and mental suffering. There is an extensive chapter on the relation of the newer ophthalmology to general medicine, biology and sociology, being an address read last year at the International Congress of Arts and Science in St. Louis. In Chapter VI the history and etiology of migraine is exhaustively considered, and numerous instances quoted to prove that very many cases of this *bête noir* of neurologists are due to ametropia. The optical and ocular influence in the etiology of spinal curvature and myopia of school children are given careful consideration and many original inferences are drawn and substantiated by striking illustrations. Dr. Gould claims that improper school desks and seats are neither the primary nor chief factors in the production of the faulty postures of school children, and that slanted handwriting, rather than a result of malposture, is in reality a method of lessening its pernicious consequences. Dextrality and sinistrality and their intimate relations with dextrocularity and sinistrocularity afford a wide field for investigation and reason. In a way, it may be said that by his forcible and original arguments Dr. Gould has pre-empted this subject as his own.

While appreciating the valuable and untiring work of the pathologists in the last two decades, Dr. Gould protests against the neglect to inquire with the same enthusiasm into the nature and methods of production of the morbid function which caused the special organic diseases, so capable of plain demonstration in the dead house and pathologic laboratory. After all our rapid advances in the domain of pathology the question recurs as to any explanation of structure except by precedent function. The essayist contends strenuously that in biology the visual function and its perversions have been an important conditioning factor of organic evolution and that the same factor is increasingly a source of evil and failure in all our sociology and pathology. Dr. Gould protests that a continuance of the past indifferent attitude of the medical profession to the importance of eyestrain is "illiberal, unscientific and self-stultifying." He urges that even in Great Britain and Germany the contemptuous appellation "American humbug" is no longer a satisfying corollary to the answer that there is no accurate or scientific demonstration of the relation of extraocular disease with eyestrain. Declaring that there is already a wealth of American articles in confirmation, Dr. Gould reproduces in his book two articles from Great Britain that he calls quite American, and almost Philadelphian, in their context and import. Mr. Simeon Snell, of Sheffield, writes exhaustively on eyestrain as a cause of headache and other reflex neuroses, and Mr. C. Ernest Pronger discourses entertainingly on the influences on the nervous system of slight errors of refraction.

The three volumes of "Biographic Clinics" have called forth much discussion, ranging from an enthusiastic praise to condemnation and contempt. That the author has been over-enthusiastic, dogmatic and emphatic has been frequently charged, perhaps with some justice. But to awaken a proper interest in such an important subject vigorous emphasis is needed. An ambiguous, timorous or apologetic brief would have fallen flat. On the other hand we fail to see what harm may follow the perusal of such entertaining and illustrative essays. Briefly the author's object is to prove by prominent biographic studies, periodical medical literature and individual experiences that, when not dependent on demonstrable organic disease, "symptoms and affections like headache, sick headache, loss of appetite, paroxysmal neuroses, cardiac palpitation or irregularity, chorea, epilepsy, neuralgia, insomnia and neurasthenia, which exhibit such waves of exacerbations and depression, may be due to ocular irritation." He makes a fervent plea for a careful examination of the refraction and musculature of the eyes in such cases, and contends that in many instances frequent re-examinations under artificial cycloplegia are necessary for the best results, even in patients past middle life. He insists that in all cases the examination should be made by a skilled ophthalmologist who has a proper belief in the importance of the careful correction of even the slightest refractive errors in cases of reflex disturbance.

Gray's Anatomy. Descriptive and Surgical. New American from the 15th English edition. Revised, enlarged and rewritten by J. Chalmers Da Costa, M.D., Professor of Surgery in the Jefferson Medical College, in collaboration with a corps of specially selected assistants. In one very handsome imperial octavo volume of 1,600 pages, with 1,132 illustrations, 500 of which are new in this edition. Price, with illustrations in black and many colors: cloth, $6.00 net; leather, $7.00 net. Lea Brothers & Co., Publishers, Philadelphia and New York, 1905.

All the features which made the former editions of this standard work valuable are retained, while a number of new ones have been added. A profusion of colored illustrations much facilitate the study of the lymphatics, veins, arteries, etc. Fully 500 new illustrations have been inserted, bringing the number to 1,132, and presenting the various subjects from new standpoints. Both the old and the new nomenclature are given, the latter in brackets, and much of the text has been rewritten to introduce the new data. The revision by Da Costa has been thorough and able, and the sections on the Lymphatic System, Abdomen, Brain, Spinal Cord and Nervous System have evidently been entirely rewritten and much enlarged, although the general plan of the book remains unchanged. This brings the number of pages to 1,600, while the index has grown to 52 pages. The edition issued in 1901 had only 1,257 pages and 41 pages of index. The arrangement of the type is an improvement, the subject of the paragraph and the catch words being in larger black type instead of in italics, as in the older editions. The book is a fine specimen of typographical work, retaining the familiar features which make it so convenient for reference and study, and which established it as the standard Anatomy half a century ago, now brought down to date.

A Laboratory Guide in Bacteriology for the Use of Students, Teachers and Practitioners. By P. G. Heineman, Sc.B. Cloth. Pp. 143. Price, $1.50 net. Chicago: The University of Chicago Press, 1905.

The principal purpose in writing this manual, the author states, was to provide a guide for the medical student through an elementary course in bacteriology. No fault can be found with the result achieved. Special stress is laid on the proper instruction of a student inadequately prepared to comprehend the all-important methods of this comparatively new and rapidly advancing branch of biology. Technical proceedings have been described at the stage of application only. The course as outlined includes all well-known pathogenic bacteria, and acquaints the student with their biologic characteristics in such a way as to enable him to recognize them by the prescribed methods. All directions are given in a clear and concise form and cover the ground of bacteriologic technic. Methods for routine examination of air, water, and milk are also described, with practical dilution tables, applicable to serum work. The chapter treating of yeasts, *molds* and torulæ enables the instructor to select such material as he may deem proper for courses in non-medical bacteriology. The book is profusely illustrated, and a list of recipes for making up special culture media adds greatly to its usefulness.

Radium and Radio-Activity Substances. By C. Baskerville, Ph.D. Cloth. Pp. 164. Price, $1.00. Philadelphia: Williams, Brown & Earle.

This work is a full account of the latest and most important development in the field of radio-active substances. Special consideration is given to the best methods to be employed for demonstrating radio-activity, with a description of the apparatus to be employed. One chapter is devoted to the application of radium and radio-active substances in medicine. The book is well illustrated. We wish particularly to commend the index, which is full and complete.

Amerikanische Streiflichter von Carl Beck. Cloth. Pp. 246 Berlin, SW., 48; Verlag von Leonhard Simon NF., 1905.

Beck's "Side Lights on America" is a reprint of articles which were written for the edification and entertainment of the readers of various German medical journals. They are bright and clever sketches in lighter vein of the sessions of the American Medical Association and of the different congresses in this country and various American institutions and happenings. He waves aloft the banner of loyalty to his fatherland through all his remarks, and never misses an opportunity to expatiate on the influence of German science and instruction on the development of American medicine. The book can be heartily recommended to all physicians who wish to perfect themselves in the most modern "student" German while seeing the profession in America and our institutions "as ithers see us," and especially "ithers" with a stronge sense of humor. His genuine admiration and appreciation of America is gratifying to one's patriotism. These nineteen articles by Beck have undoubtedly contributed toward the present good understanding between scientists on both sides of the water.

A Text Book of Clinical Diagnosis by Laboratory Methods. For the Use of Students, Practitioners and Laboratory Workers. By L. N. Boston, A.M., M.D. Second Edition. 330 illustrations. Cloth. Pp. 563. Price, $4 net. Philadelphia: W. B. Saunders & Co., 1905.

It is a just compliment to Dr. Boston's work that in a year a second edition should be demanded. This book contains most compactly and yet fully stated information on clinical diagnosis. Especially is it to be commended because of its clear description of laboratory technic, but the interpretation of clinical findings, which is the purpose of such a treatise, is quite as commendable. One hundred and thirty-seven pages are devoted to the blood, its morphology, bacteriology and parasitology. As many more to urine, its chemistry and microscopy. Succeeding sections are devoted to gastric contents, feces, sputum and buccal and nasal secretions; discharges from ears, eyes and genitalia; transudates, exudates, cerebrospinal and synovial fluids, milk and diseases of the skin. Much new material has been added in this second edition.

Pathology and Morbid Anatomy. T. H. Green, M.D., F.R.C.P. Tenth American Revised from the English Edition, Revised and Enlarged by W. C. Bosanquet, M.A., M.D. One colored plate and 348 illustrations. Cloth. Pp. 610. Price, $2.75 net. Philadelphia: Lea Brothers & Co., 1905.

A book which has reached its tenth edition stands in no need of introduction. Pathology has undergone a most astonishing transforming growth, and each year there appears much that is new and that replaces entirely, in many instances, the older conceptions and theories. This has been most notable in the fields of animal parasitology and of immunity to infectious diseases. These subjects are dealt with fully in the present edition of this work. A most excellent chapter has been added dealing with autointoxication and nutritional diseases. Many new illustrations have also been added. The standard of excellence of former editions has been maintained by the present one.

Dissecting Manual, Based on Cunningham's Anatomy. By W. H. Rockwell, Jr., M.D. Flexible Cover. Pp. 306. Price, $2.00 net. New York: William Wood & Co.

This book is divided into five parts, corresponding to those usually assigned to the student, and in each of these the bones, articulations, muscles, vessels and nerves are grouped together. The descriptions are brief, evidently based on the supposition that the dissector is thoroughly familiar with the anatomy of the part, and that the dissection is intended merely to confirm the correctness of the student's knowledge of anatomy. It is incumbent on him to recognize the structure encountered without the assistance of a descriptive guide or illustration—a very serious objection to a dissecting manual. In fact, the book is little more than an epitome. It is not illustrated.

PHYSICIAN'S POCKET ACCOUNT BOOK. By J. J. Taylor, M.D. Leather. Pp. 216. Price, $1.00. Philadelphia: The Medical Council.

This is a neat, compact book for keeping the accounts of patients individually. Entries are made but once, thus effecting a saving in time. The book, it is claimed, will be admitted as evidence in court, as it is a book of "original record." There are index pages, allowing quick reference to the numbered account pages.

STATIC, HIGH FREQUENCY, RADIO, PHOTO AND RADIUM THERAPY. By W. H. King, M.D., LL.D. Cloth. Pp. 291. Price, $2.50. New York: Boericke & Runyon. 1905.

Evidently this book is intended for the tyro in electrotherapy for the purpose of presenting to him, in concise form, a description of the apparatus needed, and what it can be expected to achieve in the way of results. The work covers only the subjects embraced in the title and does not pretend to be a complete treatise on electrotherapy. It fills the purpose for which it is intended admirably. It is well illustrated.

Miscellany

"Bile Beans."—A curious and not uninteresting light was thrown on the nature of this much advertised and vaunted nostrum in the Court of Session the other day in Lord Ardwall's judgment in an action brought by the manufacturers of the remedy against an Edinburgh chemist to inderdict him from using the name "bile beans" for any pills other than those manufactured by them. The history of "bile beans," as set forth in the judgment, is as follows: In 1896 the complainer, then 21 years of age, was in business in Australia in connection with a stationery or printing business. He had no knowledge whatever of chemistry or medicine, but happened to get introduced to the other complainer, Charles Fulford, who, though not a qualified chemist, had served five years in a chemist's shop, and had been connected with the business of a medicine company. The two complainers went into partnership to carry on business as pill manufacturers, and first started the preparation of "Gould's tiny tonic pills," which, however, did not meet with the success anticipated. In the early part of November, 1899, Fulford told his partner that at 4 o'clock in the morning he had hit on a title for a new pill, namely, "bile beans for biliousness," and he prescribed a formula for it. The pill took in Australia, and Fulford proceeded to put it on the English market. Neither the company nor the partners manufactured the pills. Even their name was misleading. They merely sent the formula to manufacturing chemists to make the pill in millions. They advertised on an extensive scale, spending £300,000 in building up the business in the United Kingdom, and issuing 83,000,000 of small illustrated pamphlets for house-to-house distribution, as well as a large number of musical advertisements. If one might judge from the way in which it was perpetually set forth in the forefront of their advertisements, the foundation-stone of their success was the false and fraudulent statement that bile beans were for the most part composed of a natural vegetable substance which Fulford discovered in Australia, which for ages had brought health and vigor to the natives of that island continent, and which was now being introduced for the benefit of civilized nations. One of the latest advertisements was entitled "Strange Japanese Customs," in which it was said, "Some years back Charles Forde, an eminent scientist, thoroughly investigated the healing extracts and essences of Australian roots and herbs, and after long research he found himself the discoverer of a natural vegetable substance which had the power of acting in the human system in the same way as Nature's own animal substance bile, and which was beyond all doubt the finest remedy yet discovered for all liver and digestive disorders." This statement, said the judge, was both false and fraudulent. There was no such person as Charles Forde, his true name being Fulford; he was not an eminent scientist, having had no scientific training and no standing whatever as a chemist or anything else; he never investigated the healing extracts and essences of Australian roots and herbs; he never made any research; he never was the discoverer of a natural vegetable substance which acted like animal bile. In fact, no such substance existed, and no such substance formed the part of bile beans, which were compounded by wholesale chemists in America out of drugs which they had in stock, no one of which had anything specially to do with Australia. The changes were rung on this wonderful discovery in every pamphlet and advertisement of the complainers. The judge had no doubt that their business was founded entirely on fraud, impudence and advertisement, though it might be that the pill was as effective as any ordinary pill so compounded to act as a cholagogue or ordinary laxative medicine; but it seemed certain that these beans would never have taken hold of the public as they had done except for "the foundation fiction of their being the product of a Great Discovery of an Ancient Australian Medicine by an Eminent Scientist using the most Advanced Scientific Methods and Apparatus."—*Medical Press* (London), Sept. 20, 1905. [Bile beans was a much advertised "patent" medicine in this country a few years ago, but it seems to have had its day.]

Asepsis in Obstetrics.—Cox, in the *Wisconsin Medical Journal*, discusses this subject with a special reference to asepsis in obstetrics in private practice. He states that we can keep as aseptic in a clean room in a well-appointed house as we can in the maternity wards of a crowded hospital, where the danger of infection is tenfold greater than it is in the ordinary American village or town home. The great trouble with many of us is that we hesitate in enforcing our own ideas of cleanliness. When called on to attend a case of confinement, if time and circumstances permit, we should see to it that the obstetric room is made as aseptic as possible. All carpets and heavy draperies should be removed, and all furniture washed in a strong solution of bichlorid of mercury or lysol. If possible insist on new mattresses and bedding. Strong lye or formaldehyd will very effectively sterilize the ordinary house floor. A common potato sprayer will carry the same solution to the walls and ceilings. If possible, the spraying should be done daily for several days prior to the accouchement. The use of the powerful antiseptic has almost entirely annihilated puerperal fever, which, we know, is frequently caused by the entrance, through some wound or abrasion, of some poisonous material into the blood. In the simplest and most natural labors slight tears are apt to exist, involving either the cervix uteri or perineum. Dirty hands, dirty finger nails, unclean napkins, soiled clothing or bedding, may be the cause of grave trouble.

A nurse should not be allowed to touch the genitalia of a patient without first thoroughly disinfecting her hands in a strong solution of formaldehyd or alcohol. Finger nails should be trimmed closely, and the stumps soaked in some strong germicidal solution. It seems hard to make the ordinary nurse understand that antiseptic means against sepsis, or putrefaction. The genital organs of the patient should be made aseptic, or as clean as possible, at the commencement of labor. Shaving the genitals is a good but not imperative practice. Any clothing that may come in contact with her should at least be washed in boiling water and ironed. The complete sterilization of all clothing is practical even outside of hospital life. The hands of the obstetrician must be thoroughly cleansed. It is not at all impracticable for us to carry in our obstetric outfits carbolic acid, lysol, permanganate of potassium and bichlorid of mercury. These, with formaldehyd and absolute alcohol, should be sufficient to make safe sterilization and disinfection in every case possible.

The use of the vaginal douche, the author believes, should be judged for the individual case. In those cases in which there is an offensive lochial discharge, an antiseptic douche should be used. Great care should be exercised, however, that this douche be given aseptically; that all apparatus necessary for giving such douche should be properly sterilized. If the nurse in attendance does not understand asepsis, it is best for the physician either to give the douche or to give definite instructions as to the method of procedure. The same rigid supervision must obtain in the use of the catheter. The great majority of nurses in attendance on obstetrical cases in small villages and rural districts know nothing of the aseptic precautions necessary in catheterization. The author believes that no patient is so deeply buried in septic filth but that asepsis or antisepsis may be carried out to a certain degree. He urges the use of one's wits to secure clean material for a bed in even the most isolated cases. He summarizes the treatment as follows: "Observe in every case absolute cleanliness, surgical cleanliness. It pays. When there exists the slightest possibility that the hands of the obstetrician may be infected or that the genital organs of the woman may conceal local germs of infection, then redouble all efforts at sterilization. The healthy, ordinary secretions of the vagina are in their effects antiseptic. Nature has here, as in many other places, interposed conservatively for the welfare of the patient. It is only when, in our bungling insanitary ministrations, we overwhelm the guardian of the citadel with hostile germs that danger results. With this natural safeguard, if we allow the parturient woman to become infected through our neglect, it is little short of a crime.

Newspaper Notoriety in Germany.—Judging from an editorial in the *Deutsche med. Wochft.*, October 12, some of our brethren in Germany have the same itching for newspaper advertising which is too much in evidence with us. We quote: "A form of advertising practiced by certain physicians is too intangible to be made the subject of a complaint before the Medical Court of Honor, and yet is unworthy of the profession and detracts from the prestige of its members. The ever-increasing tendency to strive to be talked about on every opportunity is not becoming to members of a dignified profession. Scarcely any other academic profession supplies so much purely personal material to the daily papers. Professor So-and-So is celebrating his fiftieth, sixtieth, seventieth birthday or his thirtieth, fortieth, fiftieth anniversary as physician, docent, professor or member of the privy council. In the illustrated papers appears the picture of Professor X at the bedside, surrounded by a staff of assistants, nurses and grateful patients, or of Professor Y in the office, in the laboratory, at an operation, or perhaps in his automobile. Among the 'Local Happenings' appears the item that Prince A has entered the private hospital of Dr. B; that Dr. C has been summoned to D for a consultation, or that Professor E has been made corresponding or associate member of some medical association in southern Russia, and so on. Still more regrettable is the publication in the lay press of purely scientific observations, especially when they lay before the public questions which are still unsolved and on which there are still differences of opinion. Their presentation to the public in this way has a tendency to cause the public to distrust the whole of medical science. In a recent debate von Hansemann referred to the good old days 'when it was still the custom to present scientific matters only to the scientific public. Unfortunately things are different now, and when any one thinks he has made a discovery he goes at once to one of the weeklies or dailies or to congress, and, of course, the public learns more about it than if it had been published in Virchow's *Archiv* or any other exclusively medical publication.' Recently another mode of obtaining publicity has come into vogue. We read in the papers, a few months ago, that a certain surgeon had just performed his thousandth operation in a special field, and that his fellow-citizens celebrated this unusual event with a reception and congratulations. Not long ago we noticed in a daily paper from a neighboring country that a clinician there had just performed his two-thousandth herniotomy, and that on this joyful occasion he had received an ovation in his clinic." The editorial concludes: "We gladly acknowledge that many items of this nature appear without the knowledge of the celebratee and are sincerely distasteful to him, but there is no doubt that in a large number they are directly inspired or at least favored or tolerated by the one whose name is mentioned. All the members of the medical profession must unanimously strive to change this state of affairs. Especially should the 'upper ten thousand' scorn and set their faces against these newspaper notices."

Physicians and Public Hygiene.—We hear now and then of the force of awakened public sentiment. The very phrase implies that public sentiment sometimes sleeps, and while awakening and rubbing its eyes and getting its bearings, your practical politician, who never sleeps, will snatch the prize for which he is scheming—the control of public affairs, the key of the public treasury. What is needed in this land and in this day is a live, active, wideawake, always vigilant public sentiment, not one which needs awakening or is only aroused into action by some public or official scandal. In this respect no class can set a better example than the members of the profession to which we belong; none, I fear, is more apt to feel that these matters need not engage their attention. We are, I take it, united as to the necessity of clean and well-paved streets, of a pure water supply, of an efficient system of sewage for our cities and towns, and yet of the hundreds of doctors who realize the importance of these matters, how many personally take the pains to help secure the best men and the most efficient means to accomplish these things?—Hurd, in *Buffalo Medical Journal*.

Wisdom of Belgian Judges.—A Belgian neurologist, Dr. Famenne of Florenville, conducts a family sanitarium for nervous diseases, and among his patients last year was a man of 32 who seemed to have lost all interest in life. For more than a year he had done nothing but eat, drink, sleep and wander around. He was not neurasthenic, but slightly paranoiac, and was sent to the sanitarium by a physician at Charleroi. Treatment included psychic re-education, manual labor and hydrotherapy. Among the tasks imposed by Dr. Famenne to interest, encourage and train the young man was the translation of an English work describing cures of cases of neurasthenia. He translated 40 out of the 170 pages of the book, under the doctor's supervision and encouragement. After leaving the sanitarium the young man sued the physician for $60 in payment for the translation of this work. The first court condemned the physician to pay this amount, with costs. Appeal to a second court confirmed this sentence, but reduced the remuneration for the translation to $30. The final court of appeals, however, reversed the decision and imposed the costs of the suit on the plaintiff.

Minor Points in Obstetrics.—A German confrère states that the degree of relaxation of the soft parts during a delivery may be estimated from the behavior of the lower eyelid. The floor of the pelvis yields parallel to the facility with which the lower lid can be everted. His communication was published in the *Med. Klinik*, No. 26. Winkler has also recently called attention to the necessity for warmth as a means of promoting delivery. It is a physical process, and as such is attended by expenditure of heat. If the organism is weak from anemia, fatigue or chilliness, the physical process proceeds with less energy, and it may prove necessary to resort to forceps. Before doing so, however, the patient should be thoroughly warmed, which may restore sufficient energy for delivery to terminate spontaneously. His experience has been that a warm tub bath or a sitz bath with cloths wrung out of hot water applied to the thighs and a hot foot bath are liable to start vigorous contractions. Hot drinks are valuable adjuvants. The position in the sitz bath also favors expulsion, the weight of the child and the heat irritating the lower segment of the uterus. The *Gaz. Méd. Belge* for September 28 summarizes both the above communications.

Resuscitation by Direct Massage of the Heart.—Another instance is related by Sencert, of Nancy, France. The patient was a man of 51, who had undergone an operation for gallstones, under chloroform, in 1904, without mishap. During a second laparotomy, last April, he took the chloroform well, but during the search for the obstruction in the biliary passages the rectus muscles contracted and respiration stopped abruptly. The usual measures not bringing relief in seven minutes, Sencert inserted his hand through the laparotomy wound and was able to grasp the lower part of the heart in his hand, notwithstanding the interposition of the diaphragm. He then stroked it rhythmically with his thumb in front and his fingers at the back of the organ. In five minutes after this had been commenced the heart began to grow hard and larger, and in a few moments he felt a spontaneous contraction. The contractions grew gradually stronger and stronger, the pulse returned, and the patient began to breathe. The surgeon sutured the abdomen at once, and the patient recovered without further trouble except for slight transient intercostal pains. A detailed description of the case is given in the *Jour. de Méd. de Paris*, Sept. 24, 1905.

PHYSICIAN'S POCKET ACCOUNT BOOK. By J. J. Taylor, M.D. Leather. Pp. 216. Price, $1.00. Philadelphia: The Medical Council.

This is a neat, compact book for keeping the accounts of patients individually. Entries are made but once, thus effecting a saving in time. The book, it is claimed, will be admitted as evidence in court, as it is a book of "original record." There are index pages, allowing quick reference to the numbered account pages.

STATIC, HIGH FREQUENCY, RADIO, PHOTO AND RADIUM THERAPY. By W. H. King, M.D., LL.D. Cloth. Pp. 291. Price, $2.50. New York: Boericke & Runyon. 1905.

Evidently this book is intended for the tyro in electrotherapy for the purpose of presenting to him, in concise form, a description of the apparatus needed, and what it can be expected to achieve in the way of results. The work covers only the subjects embraced in the title and does not pretend to be a complete treatise on electrotherapy. It fills the purpose for which it is intended admirably. It is well illustrated.

Miscellany

"Bile Beans."—A curious and not uninteresting light was thrown on the nature of this much advertised and vaunted nostrum in the Court of Session the other day in Lord Ardwall's judgment in an action brought by the manufacturers of the remedy against an Edinburgh chemist to inderdict him from using the name "bile beans" for any pills other than those manufactured by them. The history of "bile beans," as set forth in the judgment, is as follows: In 1896 the complainer, then 21 years of age, was in business in Australia in connection with a stationery or printing business. He had no knowledge whatever of chemistry or medicine, but happened to get introduced to the other complainer, Charles Fulford, who, though not a qualified chemist, had served five years in a chemist's shop, and had been connected with the business of a medicine company. The two complainers went into partnership to carry on business as pill manufacturers, and first started the preparation of "Gould's tiny tonic pills," which, however, did not meet with the success anticipated. In the early part of November, 1899, Fulford told his partner that at 4 o'clock in the morning he had hit on a title for a new pill, namely, "bile beans for biliousness," and he prescribed a formula for it. The pill took in Australia, and Fulford proceeded to put it on the English market. Neither the company nor the partners manufactured the pills. Even their name was misleading. They merely sent the formula to manufacturing chemists to make the pill in millions. They advertised on an extensive scale, spending £300,000 in building up the business in the United Kingdom, and issuing 83,000,000 of small illustrated pamphlets for house-to-house distribution, as well as a large number of musical advertisements. If one might judge from the way in which it was perpetually set forth in the forefront of their advertisements, the foundation-stone of their success was the false and fraudulent statement that bile beans were for the most part composed of a natural vegetable substance which Fulford discovered in Australia, which for ages had brought health and vigor to the natives of that island continent, and which was now being introduced for the benefit of civilized nations. One of the latest advertisements was entitled "Strange Japanese Customs," in which it was said, "Some years back Charles Forde, an eminent scientist, thoroughly investigated the healing extracts and essences of Australian roots and herbs, and after long research he found himself the discoverer of a natural vegetable substance which had the power of acting in the human system in the same way as Nature's own animal substance bile, and which was beyond all doubt the finest remedy yet discovered for all liver and digestive disorders." This statement, said the judge, was both false and fraudulent. There was no such person as Charles Forde, his true name being Fulford; he was not an eminent scientist, having had no scientific training and no standing whatever as a chemist or anything else; he never investigated the healing extracts and essences of Australian roots and herbs; he never made any research; he never was the discoverer of a natural vegetable substance which acted like animal bile. In fact, no such substance existed, and no such substance formed the part of bile beans, which were compounded by wholesale chemists in America out of drugs which they had in stock, no one of which had anything specially to do with Australia. The changes were rung on this wonderful discovery in every pamphlet and advertisement of the complainers. The judge had no doubt that their business was founded entirely on fraud, impudence and advertisement, though it might be that the pill was as effective as any ordinary pill so compounded to act as a cholagogue or ordinary laxative medicine; but it seemed certain that these beans would never have taken hold of the public as they had done except for "the foundation fiction of their being the product of a Great Discovery of an Ancient Australian Medicine by an Eminent Scientist using the most Advanced Scientific Methods and Apparatus."—*Medical Press* (London), Sept. 20, 1905. [Bile beans was a much advertised "patent" medicine in this country a few years ago, but it seems to have had its day.]

Asepsis in Obstetrics.—Cox, in the *Wisconsin Medical Journal,* discusses this subject with a special reference to asepsis in obstetrics in private practice. He states that we can keep as aseptic in a clean room in a well-appointed house as we can in the maternity wards of a crowded hospital, where the danger of infection is tenfold greater than it is in the ordinary American village or town home. The great trouble with many of us is that we hesitate in enforcing our own ideas of cleanliness. The contractions grew gradually stronger and stronger, the pulse returned, and the patient began to breathe. The surgeon sutured the abdomen at once, and the patient recovered without further trouble except for slight transient intercostal pains. A detailed description of the case is given in the *Jour. de Méd. de Paris*, Sept. 24, 1905.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

BOOK ON MEDICINE FOR LAITY.

Adrian, Minn., Nov. 14, 1905.

To the Editor:—Will you kindly give me the name of a good safe work on popular medicine that a self-respecting physician can recommend to the laity? M. Sullivan.

Answer: "Personal Hygiene," by W. L. Pyle, M.D., is a good one, published by W. B. Saunders & Co., Philadelphia, $1.50. Another good work, by Lyman, Fenger and Belfield, $2.50, may be had of the W. T. Keener Co., Chicago.

RESTORATION OF FLABBY BREASTS TO NORMAL.

——, Ill.

To the Editor:—Is there anything you can recommend for the treatment of flabby breasts resulting from pregnancy and parturition? I shall be pleased to know of anything that will help to restore them to their normal condition, as I am frequently consulted in this condition. A. C., M.D.

Answer: The normal rotundity and plumpness of the breasts are due largely to the deposit of adipose tissue. During pregnancy, the glands develop and during lactation become more active, and the fatty deposits are somewhat absorbed. With the cessation of lactation there is a decline in size of the glandular elements, and this, at times, without a corresponding increase in adipose tissue. Especially is this apt to be the case if the patient is poorly nourished. At times there is seen a general atrophic process in the breast structures.

The patient should be in the best possible physical condition, by proper diet, exercise, baths, massage, etc. Constitutional diseases such as syphilis, tuberculosis or anemia, should receive proper attention. Locally, massage with oil is used with good effect in many of the "rest cure" establishments.

"IN VITRO."

——, Ill., Nov. 18, 1905.

To the Editor:—I see in many articles the phrase "in vitro," which I suppose means "during life." If English is superior to another language when the same meaning is conveyed, why is the Latin used? E.

Answer.—This amusing confusion of terms by our correspondent was duplicated by several well-educated and well-read physicians of whom we asked the meaning of "*in vitro.*" It is, therefore, of sufficient interest to receive explanation here: *Vitro* evidently comes from the Latin *vitrum* (glass), and the phrase means "in glass," i. e., "in the test tube" or "in test tube experiment." Our correspondent was probably thinking of "*intra vitam*" or "*in vivo*" (Latin *vivo*—to live; be alive; or *vivus*—having life), either of which may stand for "during life." We agree that it is better to use English than Latin phrases when the meaning is the same. In this case, however, the English "in the test tube" is a little more cumbersome.

KOPP'S BABY'S FRIEND.

Omaha, Aug. 22, 1905.

To the Editor:—What is the composition of the compound prepared by Mrs. J. A. and C. Robert Kopp, at York, Pa., and sold under the shop name of "Baby's Friend"? A patient of mine gave her three-days'-old baby four drops of the stuff and the child went into a stupor at once. The pupils were pin-pointed, skin cool, and the heart beat and the respirations were slow. I treated this case as one of opium poisoning, out it was twelve hours before my little patient was out of danger.

R. E. Eskildson, M.D.

Answer—A bottle of this preparation was purchased and the contents analyzed. According to the analysis, "Kopp's Baby's Friend" contains, in 100 c.c., 0.0719 gm. morphin sulphate; approximately 1/3 of a grain in one fluid ounce.

BULL'S COUGH SYRUP.

Morocco, Ind., Sept. 6, 1905.

To the Editor:—Can you give me the formula for "Dr. Bull's Cough Syrup"? Recently I was called to see a child twenty-three months' old who had drunk about an ounce of it. In an hour, when first seen, the symptoms were those of opium poisoning. In about twelve hours the child had several convulsions and spasms followed at intervals for twelve hours longer. The child then sank into a coma and died in the seventy-second hour with cardiac failure. Respirations were labored. The dose of the mixture as labeled is five drops for a child of two years.

J. W. Shafer, M.D.

Answer.—A bottle of this preparation was purchased in the open market and the contents analyzed. According to this analysis, "Bull's Cough Syrup" contains, in 100 c.c., 0.0534 gm. morphin sulphate; approximately ¼ of a grain in one fluid ounce.

State Boards of Registration

COMING EXAMINATIONS.

Wyoming Board of Medical Examiners, Cheyenne, December 6. Secretary, S. B. Miller, Laramie.

Examining Board representing the President and Fellows of the Medical Society of Delaware at Dover, and the Homeopathic Board, Wilmington, December 12. Secretary, P. W. Tomlinson, Wilmington.

Ohio State Board of Medical Registration and Examination, Columbus, December 12-14. Secretary, F. Winders, Columbus.

Medical Examining Board of Virginia, Richmond, December 12-15. Secretary, R. S. Martin, Stuart.

Board of Medical Examiners of Maryland, Baltimore, December 13-16. Secretary, J. McScott, Hagerstown.

State Board of Health of Missouri, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

Board of Medical Examiners State of California, San Francisco, December 20. Secretary, Charles L. Tisdale, San Francisco.

California July Report.—Dr. Charles L. Tisdale, secretary of the Board of Medical Examiners of the State of California, reports the written examinations held at San Francisco and Los Angeles, July 19-21, 1905. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 93, of whom 48 passed and 45 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
University of Minnesota	(1902)	75
University of Pennsylvania	(1899)	76.7
Rush Med. Coll.	(1901) 78.7; (1903) 83.4; (1904)	76, 82

* Took only 3 subjects.

Florida October Report.—Dr. J. D. Fernandez, secretary of the Regular Board of Medical Examiners of the State of Florida, reports the examination held at Jacksonville, Oct. 10-11, 1905. Ten questions were asked in each branch, and the percentage required to pass was 75. The total number of individuals examined was 28, of whom 3 failed and 1 withdrew from examination. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Jefferson Med. Coll.	(1905)	92.8
College of Medicine and Surgery, Detroit	(1904)	86.7
Woman's Med. Coll., Baltimore	(1904)	84.8
Baltimore Med. Coll.	(1905)	95
Baylor University, Texas	(1905)	82
Howard University	(1905)	87.4
University of Kentucky	(1903)	94.2
Bellevue Hosp. Med. Coll.	(1890)	93.4
Johns Hopkins University	(1901)	93.4
Royal College of P. and S., Edinburgh	(1882)	84
Meharry Med. Coll.	(1905)	75.1

College of P. & S., Baltimore	(1903)	94
University of Georgia	(1905)	94
University of Maryland	(1905)	91.5
Vanderbilt University	(1905)	92.2

Western Reserve University	(1869)	75
Georgia Med. Coll., Augusta	(1905)	87.5
College of P. & S., New York	(1905)	92
FAILED.		
Meharry Med. Coll.	(1905)	53.2, 59.2
Jefferson Med. Coll.	(1866)	57

Vermont October Report.—Dr. W. Scott Nay, secretary of the Vermont State Board of Medical Registration, reports the written examination held at Burlington, Oct. 10-12, 1905. The number of subjects examined in was 12; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 11, all of whom passed. The following colleges were represented:

PASSED. College.	Year. Grad.	Per Cent.
University of Vermont..(1888) 76.4; (1897) 78.4; (1904 84, 89.9 (1905) 83.6, 84.6, 85.6, 88.1, 90.7..		
Jefferson Med. Coll	(1905)	79.1
Barnes Med. Coll	(1905)	83.1

The following questions were asked:

OBSTETRICS.

1. Give symptoms of placenta prævia. 2. Give treatment of puerperal fever. 3. Treatment of nausea and vomiting of pregnancy. 4. Give symptoms of extrauterine pregnancy with rupture. 5. What are the indications for premature delivery? 6. What are the indications for use of forceps? 7. Describe the mechanism of breech presentation. 8. Give treatment of eclampsia. 9. Give indications for use of anesthetics. 10 What directions would you give the nurse regarding the care of the infant during the first week?

GYNECOLOGY.

1. Give symptoms of prolapsus uteri. 2. Give treatment of dysmenorrhea. 3. Differentiate ovaritis and appendicitis. 4. Give treatment of chronic metritis. 5. Give treatment of menorrhagia.

CHEMISTRY.

1. Briefly describe molecular attraction. 2. Briefly explain disinfectants, germicides, antiseptics, deodorizers. Give example of each. 3. (a) How are normal solutions made? (b) What are decinormal solutions? 4. Mention the chief constituents of blood and state those predominating in corpuscles and plasma, respectively. 5. (a) Describe method of obtaining urea from urine. (b) Name normal pigments of urine. (c) What conditions cause an increase in the quantity of ammonia in the body?

PATHOLOGY.

1. What is the most important curative agent, not a drug, in *all* virulent infective diseases? 2. Describe the postmortem appearances usually found in acute pneumonia. 3. What pathologic appearances would you expect to find in a fatal case of pleurisy? 4. In a prolonged case of dysentery from the tropics what changes would you expect to find postmortem? 5. How do the postmortem appearances in acute miliary tuberculosis differ from those of ordinary chronic phthisis?

MATERIA MEDICA.

1. (a) How is opium obtained? (b) What percentage of morphine should it normally yield? (c) Name four alkaloids of opium and give doses. 2. Briefly give description and properties of ergot. 3. Name two arterial sedatives, and state in what condition they should be given. Give dose of same for a child one year old. 4. Give dose of Norwood's tincture of veratrum viride, digitalis, gelsemium, belladonna, sodium salicylate, potassium iodid, podophyllin, colocynth, cimicifuga, muriatic acid, bichlorid of mercury. 5. Give composition and doses of the following: Fowler's *solution*, Lugol's solution, Donavan's solution, Basham's mixture.

THERAPEUTICS.

1. Explain the principle governing the *treatment of convulsions* when due to toxic agents in the blood. Name two conditions and give treatment. 2. Name some conditions in which the bromids are indicated and state method of giving large doses. 3. Write a formula for the following: Coryza, laryngitis, gastralgia, acute articular rheumatism, delirium tremens. 4. Briefly give therapeutic indications for creosote and guaiacol. In what conditions would guaiacol be superior to creosote? 5. Name four diuretics. Give physiologic action and therapeutic indications for same.

PRACTICE OF MEDICINE.

1. Describe the symptoms and course of a case of sthenic pneumonia, unmodified by drugs, in a robust young adult. 2. What are the indications for treatment in pneumonia? How much and under what circumstances may medicines be expected to influence results? 3. How would you diagnose a case of pleurisy with effusion? 4. How does nature proceed to cure a simple pleurisy? 5. What is the difference between simple diarrhea and dysentery. 6. Give the symptoms and the most common causes of acute gastritis. 7. What are the symptoms of cystitis and how is it to be distinguished from nervous irritability of the bladder? 8. Describe the course of a typical case of typhoid fever. 9. How do the symptoms and course of acute miliary tuberculosis differ from those of ordinary chronic phthisis? 10. What are the symptoms and most common causes of cirrhosis of the liver?

LEGAL MEDICINE.

1. What is understood by cadaveric rigidity and putrefaction? 2. Describe the examination of a wound in a dead body. 3. Give causes of death in new-born children. 4. What is understood by legitimacy? 5. Give a definition of insanity.

PHYSIOLOGY.

1. Give the general structure of the nervous system. 2. What is meant by reflex action, of the nervous system? 3. Name the branches of the fifth cranial nerve, and give the distribution of the same. 4. Give the name and source of the inorganic proximate principles. 5. Give the composition of the bile, organic and mineral salts. 6. What are the normal constituents of urine? 7. Describe rigor mortis, also tetanus. 8. Describe the process of digestion and absorption of food. 9. Describe the lymphatic system, and give its function. 10. Describe the different kinds of muscular tissue, and the mode of action of each.

HYGIENE.

1. What evils arise from outside privy vaults? How may such evils be averted in cases in which these vaults can not be replaced by modern arrangements? 2. Mention the different methods of bathing and state the hygienic rules to be observed in each. 3. How would you build and furnish a school house, observing hygienic rules? 4. Give the rule for quarantine in yellow fever, also same for cholera. 5. Give the cause of diphtheria and the necessary precautions to prevent it.

SURGERY.

1. Name the three chief forms of bacteria. 2. What is suppuration and how caused? 3. Name the varieties of tumors. 4. Give the differential diagnosis between fracture and dislocation. 5. Describe the operation for removal of the breast. 6. Describe the method of skin grafting. 7. Give symptoms, dangers and treatment of acute synovitis. 8. Describe the varieties of talipes. 9. Give the treatment for chancroid. 10. What are the dangers in passing a catheter or steel sound?

ANATOMY.

1. Name the bones of the face. 2. What essential structures enter into joint formation? 3. Describe the diaphragm. Name its openings and state what passes through each opening. 4. Beneath what points on the anterior surface of the chest walls are located the valves of the heart? 5. Give the origin, course and termination of the vertebral artery. 6. Give a general anatomic description of the lymphatic system. 7. Mention the coverings of the brain. Describe one of these coverings. 8. Give the gross anatomy of the eyeball. 9. What structures are found in the right inguinal region? 10. Mention from without inward the structures covering a femoral hernia.

BACTERIOLOGY.

1. *How do bacteria multiply?* 2. What microbes are found in abscesses? 3. Name three germicides, and five antiseptics. 4. What diagnostic point can be determined by a microscopic examination of the urine? 5. In order to *prove conclusively that a* certain micro-organism is the cause of a certain specific disease, what fundamental conditions must be satisfied?

Oregon July Report.—Dr. B. E. Miller, secretary of the Board of Medical Examiners of the State of Oregon, reports the written examination held at Portland, July 13, 1905. The number of subjects examined in was 15; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 57, of whom 21 passed and 36 failed. The following colleges were represented:

The Public Service

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending November 18:

De Loffre, S. M., asst.-surgeon, *reported* for temporary duty at Presidio of Monterey, Cal.

Kneedler, Wm. L., surgeon, relieved from duty at Fort Rosecrans, Cal., and ordered to proceed to Manila, January 25, where on arrival he will report *to commanding* general, Philippines Division, for duty.

Greenleaf, Harry S., asst.-surg., relieved from duty at Fort Moultrie, S. C., and ordered to proceed to Manila on January 25, where, on arrival, he *will* report to the commanding general, Philippines Division, for assignment to duty.

Buck, C. D., asst.-surgeon, left Fort Leavenworth, Kansas, en route to accompany troops from Fort Riley, Kan., to Fort Sam Houston, Texas.

Ruffner, E. L., Brooks, Wm. H., asst.-surgeons, ordered to report in person, November 27, to Major Wm. H. Arthur, surgeon, president examining board, Army Medical Museum Building, Washington, D. C., to determine their fitness for advancement to the rank of captain.

Noble, R. E., asst.-surgeon, left depot, recruits and casuals, Fort McDowell, Cal., on 30 days' leave of absence.

Gibner, H. C., asst.-surgeon, assigned to duty as surgeon of the transport "Buford" during next voyage to Manila; on arrival at latter place will report in person to commanding general, Philippines Division for assignment to duty.

Bruns, E. H., asst.-surg., reported for temporary duty at depot, recruits and casuals, Fort McDowell, Cal.

Blanchard, R. M., Baker, Frank C., Woodbury, Frank T., asst.-surgeons, reported for temporary duty at Army General Hospital, Presidio of San Francisco, Cal.

Duncan, Louis C., asst.-surgeon, ordered to proceed from Manila, P. I., to San Francisco, Cal., on transport to sail April 15, 1906, instead of December 15, 1905.

Gapen, Nelson, asst.-surgeon, relieved from further duty in the Philippines Division, and ordered to depot of recruits and casuals, Angel Island, Cal., for duty.

Noble, R. E., asst.-surgeon, relieved from duty at depot of recruits and casuals, Angel Island, Cal., and ordered to Fort Casey, Wash., for duty.

Jones, George H., contract surgeon, left Fort Fremont, S. C., on sick leave for two months.

Rietz, Hugo C., dental surgeon, left Fort Wayne, Mich., and arrived at his proper station, Fort Sheridan, Ill.

Boak, S. Davis, dental surgeon, returned to Fort Washington, Md., from leave of absence.

Lowe, Thomas S., contract surgeon, granted an extension of one month to his leave of absence from the Philippines Division.

George, William R. S., contract surgeon, left Fort Monroe, Va., and arrived at Fort Greble, R. I., for temporary duty.

Branch, Frederick D., contract surgeon, ordered to Fort Jay, N. Y., for temporary duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending November 18:

Vickery, E. A., asst.-surgeon, detached from the *Franklin* and granted leave until December 1:

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 18:

Banks, C. E., surgeon, relieved from special temporary duty at Century, Fla., and directed to rejoin station at Key West, Fla.

McIntosh, W. P., surgeon, granted leave of absence for twenty-one days from November 15.

Blue, R., P. A., surgeon, relieved from special temporary duty at New Orleans, and directed to rejoin station at Norfolk, Va., and granted six days' leave of absence from November 15.

von Ezdorf, R. H., P. A. surgeon, directed to proceed to Biloxi, Miss., for special temporary duty.

von Ezdorf, R. H., P. A. surgeon, relieved from duty at Biloxi, Miss., and directed to proceed to Havana, Cuba, for duty.

Fricks, L. D., P. A. surgeon, directed to report to Surgeon G. W. Stoner at Ellis Island, N. Y., for duty.

Kerr, J. W., P. A. surgeon, directed to transfer inspection duty from Quebec to St. John, N. B., on or about November 17.

Richardson, T. F., P. A. surgeon, relieved from special temporary duty in New Orleans, and directed to rejoin station at Savannah, Ga.

Long, J. D., P. A. surgeon, directed to report to the Governor General of the Philippine Islands for duty as assistant director of health of said islands.

Long, J. D., P. A. surgeon, granted leave of absence for one month.

Rucker, W. C., assistant surgeon, relieved from special temporary duty at New Orleans, and directed to rejoin station at Boston.

Ward, W. K., asst.-surgeon, directed to report to Surgeon G. W. Stoner, Ellis Island, for duty.

Pettyjohn, Joseph, asst.-surgeon, relieved from duty at Fort Stanton, N. M., and directed to proceed to San Francisco, reporting to the medical officer in command for duty and assignment to quarters.

Spratt, R. D., asst.-surgeon, granted leave of absence for seven days from November 17.

Alexander, E., acting asst.-surgeon, six days' leave of absence granted from November 10, amended to read six days from November 17.

Ewing, J. T., acting asst.-surgeon, granted seven days' leave of absence from November 7, under paragraph 210 of the regulations.

Foster, S. B., acting asst.-surgeon, granted leave of absence for ten days from October 21.

Gregory, G. A., acting asst.-surgeon, granted leave of absence for fourteen days from November 11.

Stanton, J. G., acting asst.-surgeon, granted leave of absence for thirteen days from November 6.

Tappan, J. W., acting asst.-surgeon, granted leave of absence for twenty-three days from November 13.

Stearns, W. L., pharmacist, three days' leave of absence revoked.

Stearns, W. L., pharmacist, relieved from special temporary duty at Century, Fla., and directed to rejoin station at Santa Rosa Quarantine.

Gibson, F. L., pharmacist, granted one day's leave of absence, November 1, under paragraph 210 of the regulations.

Medical Organization

MEDICAL ORGANIZATION IN NORTH DAKOTA, MONTANA, IDAHO AND WASHINGTON.

By J. N. McCormack, M.D.
Chairman of the Committee on Organization of the American Medical Association.
BOWLING GREEN, KY.

For reasons which will appear later these four states group themselves together naturally for the purposes of this report. District meetings were arranged for me at Fargo and Bismarck, in North Dakota, and at Billings and Butte, in Montana. I missed connection for the appointment at Billings, but my place was ably filled by Dr. Campbell, president of the Montana State Association, and a good meeting was held. The other meetings were well attended by the local profession at each place and by such representative men from the respective states as enabled me (in the course of the free and frank discussion which always followed my talk) to get a very fair knowledge of almost everything relating to professional conditions.

I visited the state meetings in Washington and Idaho, the former at Tacoma and the latter at Boise. Both were well attended, and I have never participated in meetings in any part of the country where there was such an active and intelligent interest in every question bearing on the elevation of professional standards and the betterment of professional conditions. After every opening talk they insisted on a suspension of the regular program and devoted hour after hour to careful study of the detailed methods for building up and maintaining the interest in their county societies, by postgraduate work and otherwise, of weaving in and utilizing the district societies to the best advantage in the sparsely settled regions, of enlisting the support and co-operation of the laity, and especially of the learned professions—the lawyers, editors, teachers, clergymen and pharmacists—and of securing and enforcing medical and health legislation. In the course of these heart-to-heart talks I was able to make a study of their short, plain legislative history, and professional evolution, in a most instructive and profitable way, the more so now, because, in the light of my large experience in this work, such studies are naturally and almost insensibly comparative.

It was soon clearly developed that the Minnesota profession had builded wiser than it knew in securing advanced legislation and in fixing high standards in that state at an early day. Their laws had been copied almost literally in all four of the states, the same high standards were established under them, and in some respects with even better results. Thus North Dakota was the first state to secure an effective statute requiring that all patent and proprietary medicines containing alcohol and narcotics should show the exact amount of such substances on the label of each bottle or package. This state also has an almost ideal pure food and drug law, an excellent one for encouraging the study of anatomy, and a state bacteriologic and pathologic laboratory. The administration of the pure food, drug, nostrum and similar laws is in the hands of the chemist and director of the State Agricultural Experiment Station—a layman. He has the active co-operation of the organized profession, is executing these statutes without fear or favor, and can probably do so more effectively and with less opposition than he could if he were a medical man.

The same difficulties and opposition were encountered in securing the passage of this advanced legislation as would have to be met in the older states. Such unusual success was only possible through the able, tactful leadership of Dr. F. R. Smyth, chairman of the committee on public policy and legislation, aided by a few strong medical and lay members in both houses of the general assembly, and a united and high-grade profession, which deserved, and to a remarkable degree commanded, the respect and confidence of their representatives.

The other states included in this report have accomplished much in the same directions, more than in most of the older states, but none of them has been so successful as North Dakota, probably because they have not been so fortunate in selecting a leader.

Although the geographical and other difficulties incident to a new and sparsely settled country are more pronounced and formidable here than in many other sections of the country, and although the work is recognized here as being in its infancy, more has been really done, and there is more of the real spirit of organization, more of the unity of purpose, faith and enthusiasm, necessary to secure results, than I have found anywhere else. Careful investigation soon convinced me that these highly desirable conditions were easily traceable to two principal causes: First, to their well devised and rigidly enforced laws, and high standard examinations under them, which at an early day turned the current of graduates from low grade commercial medical colleges into less favored states. Second, and only less important, to the fact that the profession in this section is usually so well supported financially that its members can and do constantly avail themselves of the benefits of postgraduate instruction in the great medical centers, supply themselves with high-class standard and periodical literature, and otherwise equip themselves for modern scientific work, in a way possible only to a fortunate few in many parts of the country. With the minimum office consultations and prescriptions fixed at $2, day visits at $2.50 to $3, and night visits almost uniformly at $5, visits in the country $1 per mile, ordinary obstetric fees from $20 to $25, and surgical fees in the same proportion, as I found them established more firmly as my duties took me further west, it was easy to understand why higher qualifications and better equipment were within easy reach of the rank and file of the profession. It should also be said, for the benefit of those who might be tempted by this roseate picture of fees and conditions, that the climate over most of this section is very severe, that reciprocity with other states is not favored, for reasons which appear fairly satisfactory to an impartial observer, and that their examinations are such that none but well-qualified men need hope to be successful in passing them. In addition to the advantages already enumerated, made possible by the higher standards and better financial support, I was constantly impressed that there was a truer spirit of altruism pervading the profession. This has already been indicated in the greater interest taken in all affairs in regard to which medical men owe a public duty, but it was evident also in a broader and more discriminating charity for the poor. In these representative men from the mountains and plains, especially those in middle life and older, there seemed often the counterpart of Dr. William McClure, the general practitioner of the "Bonnie Briar Bush," whose story should be known, and whose noble charity should be emulated in a still higher and more discriminating way under modern methods and conditions. My constant observation is that young physicians do not do charity practice cheerfully or with good grace. I have repeatedly urged, and shall continue to do so until it is accomplished, that every medical school in this country should give a regular course of instruction in business methods, in professional conduct and in organization or co-operation, but this should always include such advice as to the obligations of the physician to the poor, to God's poor, as will guard against mistakes not creditable to such a profession as ours.

Finding that professional and public sentiment had crystallized and set in undesirable forms in most of the older states, I had long believed that it might be practicable to secure model organization and legislation in some of the new states, and hold these up as examples for their less fortunate, fad-ridden sisters. A careful study, made possible during this trip, has converted this belief into a conviction. Quackery has gained little foothold here, comparatively, and the profession has such a high place in the public esteem that if all of the forces at its command can be united, and a proper man selected in each state to lead the movement, there should be no doubt about the result. The urgent need here, and everywhere, is such an organization of the profession in each county where there are as many as four or five active physicians, as will enable them to hold meetings devoted to the discussion of questions of public policy, to which shall be invited their senators, representatives, judicial and other officers, lawyers, editors, teachers, clergymen and other leaders of thought, and educate them as no one but competent medical men can do, and which they will fully appreciate if it is properly done, not only as to the necessity for such legislation and work for the proper protection of the public, including them, their families and neighbors, but as to the duty and unselfishness of the profession in leading the reform movement. If this can be undertaken in a comprehensive, common-sense way, even in a third of the counties in each state, and, after such a leaven has worked for a while, if a well selected, tactful representative of the profession can be found, who has the respect of legislators and other officials, who knows and has the confidence of their medical constituents, and who can bring these individuals and their interests into such relationship as will prove to the interest of all concerned, and if he can be kept at the capital during each session of the general assembly, the influence of the profession in promoting its own and the public welfare would soon become irresistible. If medical colleges could only have realized and taught from the first that ours is a co-operative profession and not a competitive trade, that even as between those of the same locality there are nine good reasons for co-operation and harmony for every poor one for contention and discord, physicians would have been as harmonious as lawyers, and health and medical boards would have been just as much a part of the warp and woof of our system of government as the courts are. This is what the new plan of organization stands for, all it stands for, and if our medical schools can be induced to take up their part of the work, even at this late day, the difficulties will be greatly lessened in the states now under consideration and in the country at large.

The hospitality and cordiality of these western doctors was so warm and constant that this feature of the visit to each locality will always be with me a pleasant memory. Paraphrasing the invocation of Tiny Tim, I earnestly pray, "God bless them all; may they live long and prosper."

Illinois.

Urbana, Champaign, and Champaign County Medical Society.—A new medical organization was organized in Champaign, October 19, with Dr. William K. Newcomb, Champaign, president; Dr. William F. Burres, Urbana, vice-president, and Dr. W. E. Schowengerdt, Champaign, secretary.

Indiana.

Fourth District Medical Society.—This society, composed of physicians belonging to the medical societies in the counties of the fourth congressional district, was organized, October 26, at North Vernon, with a charter membership of about 85. Dr. William H. Stemm, North Vernon, was elected president, and Dr. James K. Ritter, Seymour, secretary and treasurer, while the presidents of the various constituent county medical societies will act as vice-presidents.

Michigan.

Fourth District Medical Society.—The first annual meeting of this society was held at Port Huron November 8. Dr. David Inglis, Detroit, president of the state medical society, delivered an address on "Medical Ideals." At the banquet, in the evening, Dr. Charles C. Clancy, Port Huron, served as toastmaster, and responses were made by leading members of the profession of Detroit and eastern Michigan.

Minnesota.

Aitkin County Medical Society.—The organization of this society was perfected at Aitkin, October 2, by the adoption of the standard constitution and by-laws and the election of the following officers: President, Dr. Carlton Graves; vice-president, Dr. J. Fowler Avery; secretary, Dr. A. G. Belsheim, and treasurer, Dr. James W. George, all of Aitkin.

Missouri.

Gentry County Medical Society.—On October 31, six physicians of the county met in Albany and took preliminary step to effect a permanent organization of the practicing physicians of the county.

Ohio.

Geauga County Medical Society.—A number of physicians of the county met in Burton, October 5, and organized this society, with the aid of Dr. William E. Lower, Cleveland, councilor of the fifth district, and Dr. Clyde E. Ford, of Cleveland. Dr. Frank S. Pomeroy, Chardon, was chosen president, and Dr. Albert D. Warner, Burton, secretary and treasurer. A committee, consisting of Drs. Albert D. Warner, Burton, Nicholas F. Schwartz, Auburn, and Ida B. Peffers, Middlefield, was appointed to draft a constitution and by-laws.

Oklahoma.

Southwestern Oklahoma Medical Association.—At a meeting of the Kiowa County Medical Association at Hobart, November 9, the question of forming a medical association for the southwestern Oklahoma county societies was taken up and favorably acted on. As a result, a temporary organization was formed, embracing Kiowa, Washita, Custer and Green counties. Dr. W. L. York, Hobart, was elected temporary president, and Dr. Alfred H. Bungardt, Cordell, temporary secretary. A permanent organization will be perfected at a meeting to be held in Cordell on Jan. 10, 1906.

Pennsylvania.

Shenandoah Medical Society.—The Shenandoah Medical Society was organized, September 27, with the following officers: President, Dr. Stephen C. Spalding; vice-president, Dr. Harry M. Wasley, and secretary, Dr. William J. Scanlan.

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

OHIO NINTH DISTRICT MEDICAL SOCIETY.

Meeting held at Gallipolis, Oct. 31, 1905.

Dr. Lester Kellar, Ironton, was chairman, and Dr. Joseph S. Rardin, Portsmouth, acted as secretary.

At the opening of the session 52 physicians were present from various parts of the district. The meeting was held at the laboratory of the State Hospital for Epileptics, and was followed by a banquet in the same building arranged by the local society.

The Business Side of Practice.

Dr. Preston Seiler, Piketon, discussed many of the evils prevalent in the profession and made valuable suggestions for improvement.

Pleuritic Effusions.

Dr. E. T. Dando, Wellston, dwelt on the insidious character of the disease and the frequency with which it is overlooked and a wrong diagnosis made. A diagnosis of tuberculosis is frequently made and the lung destroyed, or greatly crippled, before the true condition is discovered. He classified the cases as serous, serofibrinous and purulent. The causes are pneumonia involving the pleura, pyemic conditions elsewhere, infections from contagious diseases, such as scarlet and typhoid fevers, measles and whooping cough, and trauma. In some cases it follows rupture of tubercular cavities. The treatment of the serous cases is medical, either alone or with the aid of aspiration. In the early purulent cases, cure would usually follow incision, opening, cleansing and drainage. In chronic purulent cases, Estlander's thoracoplastic resection is advisable. If let alone, almost all patients will die.

In the discussion, the necessity of early and careful examination was emphasized, as was also the importance of lack of open resonance in diagnosis. Aspiration was said to be valuable when bacteria are not present, but in purulent cases free drainage is essential.

Dr. Orrin C. Andre, Waverly, advised the injection of small quantities of Thiersch's solution to replace the liquid removed by operation. He also considered the syrup of the iodid of iron a valuable remedy in the serous cases.

Dr. Brooks F. Beebe, Cincinnati, said that effusions are very often not discovered, and believed that this, in many cases, is on account of the lack of careful examination.

Perineal Laceration.

Dr. William E. Pricer, Ironton, read a paper on "Laceration of the Perineum, Frequency, Causes, Prevention, Treatment." Hospital records show that laceration occurs in about 30 per cent. of primary deliveries and in 10 per cent. of subsequent deliveries. He classified three degrees of laceration: First, those half-way to the sphincter ani; second, those extending to the sphincter ani, and, third, those extending through it. Many methods of prevention have been advised, but none is effective in all cases. In many instances it is impossible to prevent laceration, and censure should not follow when it happens. Immediate operation was advisable in almost all cases.

Dr. Charles L. Bonifield, Cincinnati, believed that 90 per cent. of primiparæ were lacerated. The only method of prevention worthy of mention was the use of chloroform in the second stage. Lacerations should be repaired as soon as possible, chromicized catgut being the best suture material.

Dr. Joseph H. Ray, Coalton, expressed his opinion that if more care were taken regarding physical exercises during the development of the girl, and in the period of pregnancy, fewer puerperal lacerations would occur.

Otitis Media.

Dr. George M. Marshall, Portsmouth, considered that many cases of otitis media are neglected and that ill results follow failure to make early incision into the tympanum, thereby evacuating infected discharges from the middle ear. Enlarged tonsils and extension of infection from the exanthemata are the chief causes of this condition.

Banquet.

The association adjourned to meet at the Banquet Hall, where the local society had provided substantial entertainment. Dr. John B. Alcorn, Gallipolis, acted as toastmaster.

NEW YORK NEUROLOGICAL SOCIETY.

Regular Meeting, held Oct. 3, 1905.

The Vice-President, Dr. J. Arthur Booth, in the Chair.

Types of Hysterical Insanity.

Dr. Robert C. Woodman read a paper on the outcome of a symptomatic study of the insanities during the past two and a half years. Cases not clearly belonging to any well recognized insane type had been especially scrutinized, and some had been found to show hysterical stigmata, while other atypical cases without stigmata presented mental symptoms very similar to those of the hysterics. His observation and study had shown that there were among the committed insane a considerable number of hysterics, and those cases were, in many instances, violently insane for considerable periods. Any medical classification that ignored that fact was incomplete, and concealed important clinical distinctions. The recognition that some hysterics, as such, were insane, helped to bridge the gap between mental diseases and general medicine, and made more easy the conception of other insanities as thinking disorders; as functional in the same sense as ordinary thought was functional.

Dr. Woodman's paper, in summary, analyzed the symptoms that insane hysterics presented. He found the origin of the attack in emotional experiences; it pursued an episodic course; there was an absence of marked disturbance in the stream of thought, excepting in dazed and stuporous states; there was a natural point of view concerning indifferent topics; often periodic amnesia; a loss of the ability to do mental or physical work, but with little or no motor retardation, and, on the emotional side, usually anxiety and fear. Cases were quoted in which the anxious depression preceded the hysterical stigmata, notably in one involutional case, and the question of a close relation of hysteria to anxious depressions at any time of life was raised, especially as to its relationship to recurrent melancholic attacks without manic alternations. Some non-conclusive evidence on the relation of hysteria and dementia præcox was submitted, and some other symptom complexes which hysteria had been found to take were referred to.

DISCUSSION.

Dr. Adolph Meyer said that the hysterical insanities are a rather interesting group from a theoretical point of view, inasmuch as they represent one of the clearest types of mental disorder, in which the psychogenic element is uppermost. Their recognition is also of decided importance from a prognostic and therapeutic point of view. A large number of the cases—indeed, the majority of the attacks which rank plainly as insanities, are, however, of a rather transitory character, and for that reason, perhaps, there is need of a detailed knowledge of the disorders, for their treatment has thus far aroused comparatively little interest. That phase of the subject must of necessity be preceded by a study in broad lines of the symptom-complex, such as Dr. Woodman's paper gave. While in some there was a distinct history of hysteria, with hysterical stigmata well marked, and the whole mechanism of the disease characteristically hysterical, there were others in which the symptom-complex seemed to coexist with well-recognized forms of insanity, such as dementia præcox and the manic-depressive type, as well as involutional melancholia; and his suggestion concerning the latter is certainly worth attention; but under those conditions it was usually apparent that it was subordinate to the more decisive phenomena of the major affection. Some points which had of late been especially touched on in the literature of hysteria; namely, the ganser complex, had not been especially considered by Dr. Woodman, and perhaps with some justification, as it might well be regarded as an afterfact of clinical investigation, when it goes beyond the scope of the analogous states actually described.

Ricklin, published in the *Psychiatrische Wochenschrift*, and reviewed in the *Psychological Bulletin* of July, 1905.

Dr. Arthur C. Brush said that if we accept the old idea that hysteria was a mental phenomenon that was to a greater or lesser extent met with in the entire human race, it would be difficult to see how Dr. Woodman could differentiate between these so-called hysterical insanities and the true insanities. That the former were nothing but exaggerations of what was normally present in the human being is undoubtedly true, for even sane people have at times hallucinations and delusions and automatic dream states. The sudden onset of the symptoms in these cases of so-called hysterical insanity, and the sudden recovery from them, would sharply distinguish them from cases of true insanity, as would also the lack of mental deterioration. Dr. Brush said he did not wish to be understood from this as questioning the propriety of proper treatment in dealing with cases of so-called hysterical insanity, but until we could clearly define insanity and hysteria, he did not think we could accept the latter as a form of insanity.

Dr. William M. Leszynsky said that as a rule it is exceedingly difficult or impossible, in the majority of cases to make a satisfactory or accurate determination of the visual field.. For this requires on the part of the patient, persistent concentration of attention and considerable judgment. It is possible, however, in some cases to decide as to hemianopsia or marked concentric contraction.

Dr. George W. Jacoby said he was rather surprised to learn that this class of cases was considered in any way unusual, and he could only explain this on the ground that they were regarded from a different standpoint by the psychiatrist and alienist in contradistinction to that of the neurologist. The latter regards many of the somatic features of hysteria as distinct delusions, and if that interpretation is correct, then it is only one step further to the development of distinct insanity.

In the recognition of these cases of so-called hysterical insanity it would be necessary to study the previous history of the patient, and exclude the various other forms of insanity, such as epileptiform insanity, delirium of various kinds, catatonia, etc. Given, a case in which there was a previous history of hysteria, together with the course and clinical features pointed out by Dr. Woodman, and the diagnosis of hysterical insanity could in time be made, but whether a diagnosis could be made from the course alone, without such a previous history of hysteria was questionable. The value of such an early diagnosis lies chiefly in the prognosis and treatment, but the speaker said it would be a decided mistake to believe that all cases of hysterical insanity were of short duration. He recalled instances where recovery was delayed for two or three years.

Dr. Jacoby said he agreed with Dr. Leszynsky that it would be exceedingly difficult to base the diagnosis of hysteria on [illegible], such as restriction of the visual field, hemianesthesia, etc., because patients of that class are usually very unreliable in their statements, and susceptible to suggestions of all kinds.

Dr. Edward D. Fisher said he would certainly draw a distinction between cases of mental disease occurring in those who gave a previous history of hysteria and in those who gave no such history. The former, as a rule, do not run the typical course observed in melancholia, or in so-called mania, using the older terms, but they may assume more of the paranoic form. The duration of these hysterical insanities, as Dr. Jacoby had said, is often prolonged. He recalled cases of this kind where restraint became necessary on account of the development of suicidal or homicidal tendencies, and where some mental instability persisted for some time after the disappearance of the acute symptoms.

Dr. J. Arthur Booth said that the type in which there are convulsive seizures and hemianesthesia, with narrowing of the visual field and marked emotional disturbances, is not difficult to recognize. In some of the other types referred to, however, the diagnosis of hysterical insanity should be made with great circumspection; for just as in many organic diseases of the nervous system hysterical disturbances are not infrequently observed, so in certain psychoses, other than the one under consideration, emotional disturbances occur, which would not justify one in grouping these cases as types of hysterical insanity.

Dr. Woodman said he believed that in hysteria both the physical symptoms and such mental disturbances as are regarded as insane have a common basis in a characteristic thought disorder. He did not wish to be understood as presenting the provisional classification of the cases he had reported in his paper as a classification of hysterical insanity. He simply used these headings as guide posts to give some idea of where, among the many groups of insanities, we might look for the hysterical type.

Dr. August Hoch, of Bloomingdale, read a paper on "Flight of Ideas."

PHYSICIANS' CLUB OF CHICAGO.

Regular Meeting, held Oct. 24, 1905.

Dr. Frank Billings in the Chair.

The subject under discussion was "The Establishment of a Permanent Medical Home and Library for the Physicians of Chicago and of Cook County."

Suggestions as to Organization.

Dr. Charles L. Dana, New York, outlined the history of the organization of the New York Academy of Medicine, and offered suggestions concerning the establishment of a similar organization in Chicago. The New York Academy of Medicine was founded in 1847, when there was no other medical society, for the purpose of affording physicians an opportunity to meet together and discuss scientific problems. The original membership numbered 200. Incorporation papers were taken out later, so that the society could own property. In 1872 a library was started, and in the early 80s the society purchased a building worth $30,000. It was early felt that the influence of the medical profession should be exerted for the public welfare as well as for the promotion of medical science, and the society has always taken an active part in the promotion of sanitary measures. It was through the influence of the acadamy that the city board of health was established, and through the activity of its members the medical supervision of the school children was instituted. The society has never interfered directly with nor has it attempted to promote medical legislation, except in those broad measures which involve the general well-being of the public. Its membership has always maintained a high standard. The academy owns a library of 90,000 volumes, containing not only all the standard works and monographs, but a full series of the most important medical journals of the world. The library is open to the fellows day and evening for most of the year; to non-members it is open for a certain number of hours during the day, and the public also are permitted to use it on presentation of the card of a fellow. Members are entitled to borrow books, and books are sent to them while they are away from tne city.

In 1889 funds were raised by contributions and donations to erect the present home of the academy. This building has a capacity for a large library, has meeting rooms for the different branches of the academy and other medical societies, a central hall, parlor and refreshment rooms. The academy now owns property worth $700,000, all of which has been accumulated during the past twenty-five years. The academy has not undertaken any original investigation in any special line of work, directing its energies solely to the promotion of sanitation and the study of problems connected with public medicine. It brings before the public and the profession itself questions involving hospital organization, and public education, and always has in mind the fact that when its influence as a great medical body can be exerted in behalf of proper action by the state, it will be so exerted.

The academy is accessible to every educated physician of good standing and of at least three years' experience. It provides opportunities for consulting one of the best libraries in the country, and for presenting and discussing medical problems. It provides social opportunities for its members and aims to keep clear of all cliqueism and politics. The membership is limited to 1,000. There are 100 non-resident fellows and a few honorary fellows. The fellows pay an initiation fee of $20 and annual dues of $10. The non-resident members pay half that sum.

A board of trustees, consisting of five members, has control of all the finances of the academy. The executive work of the academy is in the hands of a council, which consists of the president, three vice-presidents, two secretaries, the treasurer, the five trustees, the chairman of the committee on admissions, and the chairman of the committee on library, a total of fourteen. The council attends to the general management of the academy. Working under the council is the librarian, who is also the executive officer of the council. The income of the academy from trust funds amounts to about $2,500. The income from dues amounts to about $17,000. The income from other funds, such as initiation fees, etc., amounts to $18,000, making a total annual income of about $37,000. The annual maintenance of the library is about $14,000; maintenance of building, including heating, lighting and insurance, and salaries, about $11,000; expenses for scientific and organization work, about $2,100. The surplus is placed in a sinking fund.

The scientific organization of the academy is as follows: There is a central body, which meets twice a month for eight months in the year. These are the stated meetings of the academy. One of these meetings is devoted to an annual discourse and to the delivery of an endowed lecture on some medical topic. The academy is divided into nine sections, each of which has a chairman and a secretary. These sections have the free use of the academy for their meetings. Each section pays its own running expenses. The chairman of the section has full control of the work of that section. Once a year each section must present before the general body of the academy a paper or a discussion which is expected to show either some special development in that particular branch of medicine or which details the relationship of that section to general medicine. The sections meet once a month.

The College of Physicians of Philadelphia.

Dr. W. W. Keen of Philadelphia wrote that this, the oldest medical body in the United States, was founded in 1787. The college holds a scientific meeting once a month, and monthly meetings are held by a number of sections. The college has been the professional adviser of the city in matters of health and hygiene, especially in times of epidemics or other emergencies involving the health of the city. It is also a center for professional meetings, and some non-medical organizations assemble in one of the meeting rooms. No rental is charged these societies, because the college is exempt from taxation. A small fee is charged, however, to cover the expenses of heating, lighting and janitor service. Originally the college met in private houses, later in a room in the Pennsylvania Hospital. In 1865, through bequests, subscriptions and donations, a sufficient sum was obtained to erect the building now occupied by the college. The library contains over 75,000 volumes and 75,000 pamphlets, besides a number of duplicates. The growth of the library has come from gifts of publishers, of fellows, and of friends of the college, public institutions and hospitals, medical societies and bequests of deceased fellows. Through the influence of fellows of the college library funds have been established as memorials of doctors, or of non-medical persons. The endowment funds of this character, which are only available for purposes of the library, amount to about $65,000. Two other sources of additions to the library exist; one is the journal club, to which a large number of the fellows subscribe $3 a year, the journals going directly to the library, and the other is a directory for nurses established by the college some years ago and which more than pays for itself. The profits accruing from this directory go to the library.

Establishment and Maintenance of a Medical Library.

Dr. Nicholas Senn said that in Chicago the time is ripe for taking active steps for the establishment of a library that will be a credit to the city and to the profession. The physicians need only the encouragement of example to take an active interest in such an undertaking. He has made an attempt, by example, to furnish a nucleus for such a library by donating to the Newberry Library the largest portion of his own library, including the surgical library of Professor Baum, and the physiologic library of Professor Dubois-Raymond. Dr. Senn said that when the Chicago profession has a permanent home he proposes that that collection shall grow where it shall be accessible to all physicians. It is his purpose also that that collection shall become the best and largest antiquarian medical library in the world.

Plans of the John Crerar Library.

Mr. Charles Andrews, librarian of the John Crerar Library, outlined the plans of that institution with reference to the provisions the library intends to make for a permanent home for physicians, as well as a place for the Senn library. The new building of the Crerar Library is to contain suitable meeting rooms for medical societies and their committees, as well as rooms for the secretaries, which may be used as society headquarters.

Cleveland Academy of Medicine.

Dr. P. Maxwell Foshay related the method by which the city of Cleveland acquired a permanent home and a medical library. Twenty-five doctors formed a society whose annual dues are $25. The running expenses were kept at $1 per capita, and the balance was invested in interest-bearing securities. A few years later the Cleveland Medical Library Association was organized, with three classes of members. Those who held the franchise paid annual dues of $30. An active membership cost $10 a year, and an associate membership $3 a year. Subscriptions and donations were solicited from outsiders. Enough money was raised to make a payment of $10,000 on property valued at $14,000. The house was remodeled to suit the purposes of the association, and books were secured by gift and by purchase. The association is now engaged in raising funds to erect a large auditorium and to make additions to the present home.

Other speakers were Dr. D. R. Brower, Dr. I. N. Danforth, Dr. C. S. Bacon and Dr. L. Harrison Mettler.

AMERICAN ACADEMY OF MEDICINE.

Thirtieth Annual Meeting, held in Chicago, Nov. 9-10, 1905.

(Concluded from page 1598.)

Effect of Recreation on the Nervous System.

Dr. William James Herdman, Ann Arbor, Mich., said that when we undertake to consider recreation after toil as a need of the human organism it is in some part, if not in the whole, of the nervous system, where that need has arisen. This is quite as true of mental as of physical labor, of emotional expenditure of energy as of that which results in glandular secretion; it is the nervous system which must "pay the piper," for it is in its structure chiefly where the need for molecular reconstruction has arisen. A life that is all work, narrow in its range, pouring out its store of nerve energy in muscular effort, unvaried, monotonous; an occupation that makes a mere machine of both body and mind, and keeps that machine incessantly employed day in and day out, gradually, but surely, leaves its permanent imprint on that plastic substance, the nerve tissue, which serves as the medium of action and reaction between the physical forces on the one side and the mental and spiritual on the other. It becomes fixed and restricted in its channels of communication. Both the receptive and expressive capacities of the mind of such a man atrophy from disuse, destroying the possibilities of a larger life. Continued and unvaried draughts on the reservoir of energy, which every nervous system has stored, no matter through what channel the depletion takes place, not only disregard directly the law of recuperation for the organs so used, but indirectly through the neglect of other faculties, limit the sources from which new supplies of nerve force might be supplied.

Recreation, physiologically speaking, is local sleep for an exhausted part, not general sleep, and the fundamental principle of all recreation consists in this local rest which is secured by a change of organic activity. In the brain of man, with its common source of nutrition, but with its complex centers and functions acting independently, the plan best suited for recuperating lost force in a functionating center is to excite activity in some associate center. The needed conditions in blood supply and lymphatic action, in commissary and scavenger service, are thus maintained, and the work of reconstruction is hastened and promoted. If, at the same time, the processes of nutrition are accompanied by agreeable emotions, the organism is in the most favorable state for quick and abundant restoration of energy to the exhausted part. In stating that recreation consists in shifting the activity from an exhausted to a rested area of the nervous system, no new fact has been revealed nor any new principle evolved. The practical methods by which suitable recreations are to be selected to meet the requirements of special classes or individuals must start from this fundamental principle, but they will vary as taste, occupations and opportunities vary. From the complexity of occupations in which our fellows engage there results the greatest variety of channels through which the store of nervous energy is depleted. Likewise taste, inclination, interests and opportunities for their exercise are so various that the transfer to congenial and, at the same time, possible activities as recreative means is largely a matter for individual decision. Outdoor plays and games, requiring some skill, such as boating, fishing, swimming, skating, horseback riding, gardening, toolwork and the like, are of much more recreative value than any of the artificial gymnastics which have no purpose nor incentive beyond the movement itself. For the brain worker, the way is open to recreations innumerable, and the opportunity for choice and the possibility of varying their character at will makes the problem of healthful living an easy one if a man would cultivate a sufficient variety of interests, so that when one channel of activity is, for any reason, closed to him as a relief from necessary work he can choose another. The practical result in this is seen when we compare the statistics of health and longevity of the brain-worker and of the muscle-worker. The researches of Beard and others have shown that brain-workers not only live from 14 to 20 years longer than muscle-workers, but that their health is more uniformly good and their stature of larger average. When mankind is once emancipated from the conception that honest work is contemptible drudgery and learns to recognize the pleasures and recompense it has in store when rightly apprehended, which means that the work selected must be suited to individual capacities and tastes, and when greed and selfishness give place to a spirit of mutual helpfulness, the problem of recreation will be solved.

Recreation as a Sociologic Factor.

Dr. Donly C. Hawley, Burlington, Vt., said that, while work is necessary and ennobling and is the law the universe obeys, refreshment of the strength and spirits after toil is likewise a necessity, which finds expression in the natural cravings of the social instinct and in the general desire for diversion and amusement. The social instinct demands satisfaction, and will find it in recreation and amusement, which is either beneficial and uplifting, or injurious and degrading. In attempting to bring about the social benefit of the working classes, of the very poor and of the criminal and vicious elements in any community, the first and greatest need is healthful recreation. One of the great sociologic needs of the day is admittedly a solution of the so-called labor problem, but of equal importance and hemmed about with greater difficulties is a solution of the leisure problem. One of the ways of bringing about the social betterment of the masses, in the opinion of the author, is by providing proper channels for the expression of every social want and every social sympathy. The author thinks that if we can improve the conditions and surroundings of the children of the poor, give them educational and industrial advantages, and control their amusements and recreation, we shall have solved, in a large measure, an important problem for the next generation, as formative processes will, in large measure, render unnecessary those which are reformatory. This applies with force to children in all classes of society. Parents should recognize the fact and the necessity of furnishing at home, and in properly conducted places, amusements and recreation which shall be satisfying and at the same time uplifting and educational. Teachers everywhere should also be made to realize the importance of this question and to use the opportunities which their positions afford in influencing the children under their care to seek recreation which recreates and amusements which will bring the most perfect joy.

Physiology of Recreation.

Dr. George W. McCaskey, Fort Wayne, Ind., said that the primary predominant factor in practically all forms of recreation is the psychical one. The sudden change from a state of extreme depression and misery, with perfectly distinct physical suffering, to one of buoyancy and exultation, with entire forgetfulness of self, as a result of a change of emotion, is a not unfamiliar experience in the lives of most people. If the various forms of recreation are closely scrutinized, it would be found that those diversions and amusements which produce the promptest and most brilliant effects on both the mental and physical states of those who participate in them, are precisely those in which the psychical impression is the strongest. The first requisite in what may be termed successful recreation is a complete diversion from self, a complete submergence of self-consciousness, which inhibits that everlasting introspection of our physical selves which is the foundation of half the morbidity of the world. How this can best be done is a problem for the individual and depends on his age, sex, social status, intellectual development and other factors which go to make up the complete ego. McCaskey called attention to the purely physical or mechanical aspects of many forms of recreation, and said that the systematic introduction into our lives of such recreation as is suited to the individual needs should be the rational aim of all, and a proper understanding of the physiological laws and facts which underlie the whole subject can not be otherwise than helpful. He concludes with the admonition of Virgil that "rural recreations abroad, and books at home, are the innocent pleasures of a man who is early wise."

Relation of Recreation to Education.

Dr. R. K. Row, superintendent of schools, Berwyn, Ill., presented a brief statement of the recognized psycho-physical theories of play. First—The surplus energy theory assumes in the higher forms of life a series of inborn impulses for whose serious activity there may be, for a long time, no opportunity of discharge. As a result a reserve of exuberant energy collects and presses for employment, thus calling for an ideal satisfaction of the impulse in the form of play. Second—Teleologic theory begets a tendency in the organism to practice those activities that will be needed later in life; a means of getting control of the racial inheritance of co-ordinated power and skill. Third—The organic selection theory, in part at least, includes the first and second. From the random movements of the preconscious control period the organism selects those that give pleasure and repeats them; later, these and the movements of associates, are imitated and the pleasurable activities persist in playful repetition because the organism finds them to be vital to conserve life and promote growth and development so long as growth is possible. Out-of-door games, plays and recreations are the best means of physical education. Co-operative games promote social education. They develop the qualities of leadership, self-reliance, self-control, and the spirit of co-operation in social groups. Recreation is a very large and vital factor in esthetic education. Recreative activities have also important ethical functions.

Ceremonials and Festa in the Recreation of Larger Groups of Individuals.

Dr. Bayard Holmes, Chicago, said that the value of the pageant has been well recognized by every organization which has aimed to secure a control over public opinion and public life. The educational and social function of the pageant can not be confined to any one class or age. It has a use for every class and for every member of society. The wonder of the child and his imagination are touched by the color and tinsel and tawdry illuminations as by no reality of life. For the youth the occasion is one of unequaled liberty and freedom from restraint. He attains almost the buoyancy of the savage. For the young adult it furnishes the occasion for prenuptial amenities. For those in the prime of life al opportunity is given for the display of success in any and every activity of life. The social, the economic and the political success can be ostentatiously exhibited without the odium of effrontery or vulgarity. Even the aged may receive the scanty satisfaction of an honorable decline. But the extension of the influence of the pageant and the communal festivity reaches farther and cultivates and encourages every joy-giving activity of life.

Medical Features of the Papyrus Ebers.

Dr. Carl von Klein, Chicago, described the papyrus in general and in detail and discussed prehistoric medicine from about 5,000 years before the Christian era to Hippocrates. The paper will appear in The Journal.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Oct. 25, 1905.

The President, Dr. James M. Anders, in the Chair.

Operative Treatment of Fractures of the Patella.

Dr. John H. Gibbon stated that the two factors which render the non-operative treatment of fractures of the patella difficult are, first, the attachment to the upper fragment of a powerful group of muscles which, if not properly controlled, constantly tend to separate the fragments, and, second, the interposition of ligamentous or tendinous structures between the fractured surfaces. The latter are the most important and most difficult to overcome and can not be obviated except by operation. The operation is justifiable if done in an absolutely aseptic manner. In every case the fragments of the broken patella are covered with fibrous tissue. Multiple fracture is another complication which makes mechanical coaptation uncertain and difficult. Gibbon believes that the treatment of fractures of the patella should consist either of the simple splint method or of one of the operative procedures which include a complete exposure of the fractured bone and torn ligaments. All the intermediate methods, while possessing none of the advantages of the open method, have the same danger as the open method, namely, sepsis. Reference was made to Stimson, who, in about forty cases in which the subcuticular suture was used, had two severe infections with stiff joint, while in a series of about two hundred cases treated by the open method there was but one slight infection and no stiffness of joint. Suture of the bone alone has passed out of use, the operation being done either by a simple suture of the lateral ligaments and fibrous tissue over the bone, or this with the addition of one or two sutures through the patella itself. Early operation is advocated. When operation is not done immediately, a tight bandage with ice bags should be applied to prevent effusion of blood. The incision recommended is a transverse curvilinear one, allowing easy access to the torn ligaments. An absorbable suture, preferably chromicized catgut, should be employed and the sutures should not be tied very tight. The leg should be dressed on a posterior splint and well elevated; the dressing changed at the end of a week and the stitches removed. Later the splint should be removed at frequent intervals and massage practiced. After three or four weeks the splint could be discarded, when the patient is in bed, and massage regularly employed. He advises passive flexion of the leg after four weeks. The period of convalescence after the operative treatment is less than half that following the splint method. The operative treatment should only be undertaken in a well-appointed operating room by a surgeon who has developed the "aseptic habit." Where the operator has not had a great deal of experience, and where the surroundings are not perfectly aseptic, it is wiser and safer to pursue the splint treatment, for, if suppuration occurs, a stiff joint, the loss of the leg, or even death might result.

DISCUSSION.

Dr. John B. Shober referred to the development of the open method and attributed the success attendant on it to the greater attention given to the ligaments in freeing the overlapping fibrous tissue. Formerly the major attention was given to the coaptation of the bones by the use of silver wire. He agreed that the operation is a serious one and to be undertaken only under conditions pointed out by the author.

Dr. John B. Roberts believes that the operation is a good one, but that in the treatment of fractures there is needed an operation which the average man can do, so that it would not be necessary to send all patients to experts. With the proper sterilization of the parts, the needle and the thread, with the subcutaneous purse-string suture, a practical and satisfactory operation is offered. The periosteum falling between the fractured ends of the bone he gets rid of by rubbing the two parts together. This operation is so simple that it ought to take the place of the more serious ones which can only be undertaken under ideal conditions.

Dr. William L. Rodman believes the subcutaneous operation more dangerous than the aseptic open method. The open operation should be surrounded with restrictions in old subjects and in patients with visceral disease and confined to young men leading active lives. He does not believe that the soft structures falling between the ends of the bones can be eliminated, except by the open operation. He agrees with Dr. Gibbon in the advantage of the curvilinear incision. He does not approve of the use of buried silver wire, and has come to regard wiring the bone as being unnecessary. He prefers to wait for the subsidence of the acute inflammatory symptoms before operating.

Dr. A. C. Wood agreed with Dr. Gibbon in practically all he said. He believes that modern surgery tends more and more to get away from subcutaneous operations. A man who can not be trusted to open a joint can not be trusted to pass a subcutaneous ligature. He makes the incision above the patella through a part of the skin which is thick and on which there is no pressure. This also favors drainage. He still unites the bone, as well as the capsule and ligaments, though the method employed is a modification of that formerly practiced. When the parts are brought together, the knot is at a point where there is no pressure.

Severe General Infection of Obscure Origin.

Dr. H. B. Allyn reported two cases of severe general infection. The first patient, a boy, 4 years old, complained of abdominal pain, had vomiting and delirium, and died on the third day of a sudden, large, pleural hemorrhage. At autopsy pure cultures of an undescribed form of colon bacillus were obtained from the spleen and an enlarged mesenteric gland, and the same organism was found in the culture made from an enlarged Peyer's patch. The disease was not hemorrhagic typhoid. The second patient, a boy, 9 months old, developed, in succession, a small patch of consolidated lung, vomiting, purpura, otitis media, arthritis, bronchitis, nephritis, meningitis, and died after an illness of twenty-five days. There was no autopsy. Cultures made from the throat mucus and the spinal fluid showed only a small diplococcus, which was not that of pneumonia or cerebrospinal meningitis.

A New Method of Surgical Anesthesia.

Dr. W. Wayne Babcock called attention to the fact that the mandragora used by surgeons from the time of Herodotus until the thirteenth century contained scopolamin, which has now, after the lapse of seven centuries, been re-introduced into surgical practice. Babcock has experimented with a number of solonaceous and hypnotic alkaloids, and finds that apomorphin is the most powerful adjuvant in scopolamin-morphin narcosis. When aided by apomorphin, over 70 per cent. of the patients have been successfully narcotized, while previous writers have only succeeded in narcotizing from 9 to 26 per cent. of their patients, the remainder requiring ether or chloroform. The method is as follows: One-sixth gr. of morphin sulphate, with 1/100 gr. of scopolamin hydrobromate, is given one hour before the operation, followed by an edema containing spiritus ætheris comp., ½ oz.; spiritus fermenti, ½ oz.; warm water, 4 ozs. Fifteen minutes later the hypodermic is repeated, and twenty minutes after the second hypodermic, a third containing 1/100 gr. of scopolamin, with 1/30 to 1/12 gr. of apomorphin hydrochlorate, is given. The dose of apomorphin is regulated by the condition of the patient and the strength of the pulse, and is usually followed in from three to ten minutes by surgical anesthesia. If the patient shows a tolerance for drugs, the apomorphin, at times associated with morphin, is repeated in a dose proportionate to the patient's condition. In a small percentage of cases which prove rebellious to the narcotic, it might be desirable to administer cautiously a minute quantity of ether or chloroform rather than to repeat the injection of the narcotics. The anesthesia produced, as a rule, lasts two or more hours, and the patient usually is in better condition toward the end of the operation than near the beginning. The method has been used successfully as the sole anesthetic in operations on the skull, face, larynx, gall bladder, stomach, kidneys, pelvic organs and extremities, and Babcock thinks it has a special field in operations involving the upper respiratory tract.

Notes on General Anesthetics, with Special Reference to *Scopolamin-Morphin Anesthesia.*

Dr. A. C. Wood's paper corresponded closely with Dr. Babcock's. His experience regarding the time required for full anesthesia differed somewhat from that of Dr. Babcock. The real difference is not so much due to the idiosyncrasy of the patient as to the question of a reliable and uniform preparation of the drug. The contraindications for administration are of more importance than the indications. This form of anesthesia might be used in any case in which there are no contraindications, provided absolute muscular relaxation is not essential. It is a satisfactory adjuvant to ether and chloroform. He would hesitate to use it in operations involving the mouth and air passages, fearing that with the profound narcosis sometimes produced the patient could not take care of the mucus or blood in the mouth. In 15 cases in which he has used it, the success might be considered perfect in 8. In one appendectomy there was no movement of the muscles, no nausea, and the convalescence was satisfactory in every way. He believes that the results in the use of the anesthetic would be better in proportion with the greater care exercised in its selection and administration.

DISCUSSION.

Dr. William L. Rodman's experience with this form of anesthetic was limited to one case, and that one case enabled him to confirm what had been said by the two essayists. While the anesthesia was not complete, it was made so by a very small quantity of ether. He thought that it could only be looked on as an adjuvant to ether and chloroform. He thinks it might be of much value in operations on the genito-urinary tract. He thinks all surgeons are remiss in not more fully availing themselves of the use of nitrous oxid preceding the administration of ether.

Dr. Ernest Laplace has used scopolamin-morphin a few times, and, while the effects are encouraging, he has not dared go as far as indicated by the papers read. He stated, however, that, with ether as a concomitant, there have been but very few subsequent unpleasant symptoms.

Dr. Alice M. Seabrooke referred to three cases at the Woman's Hospital in which scopolamin-morphin had been used with success. One was a case of carcinoma of the omentum, one a hysterical child, and the third case that of an aged woman with gallstones.

Dr. H. C. Wood thinks morphin anesthesia a better term than scopolamin-morphin. The question of the introduction of a new anesthetic depends on its comparative safety. The number of cases in the present issue is so small that no absolute deductions can be drawn. It has been demonstrated that the administration of morphin preceding ether lessens many of the unpleasant sensations produced by ether, but it depresses respiration. Nitrous oxid gas is a much better drug to precede ether.

Dr. John B. Roberts said that if scopolamin is identical with hyoscin he can not understand the necessity for such small doses as had been indicated.

Regular Meeting, held Sept. 13, 1905.

The President, Dr. J. M. Anders, in the Chair.

Anorexia in Infants in Hot Weather.

Dr. Maurice Ostheimer called attention to this condition, in which often the only symptom is the refusal of the child to take the proper amount of nourishment. To find cause for this loss of appetite, when there are no symptoms, he said is difficult, and there must be considered the possibility of functional derangement of the gastrointestinal tract. In one case an increase of the proteids in the milk mixture up to 2 per cent. helped the child, but only after two months did the child take more food at each feeding. In some cases he stops all food and gives barley water and whey. He especially called attention to the fact that anorexia occurs only during hot weather and that often it is cured only by removal to a cooler climate.

Rest in Tuberculosis.

Dr. William B. Stanton considered the treatment of tuberculosis under the heads of: 1, Abundant food; 2, fresh air; 3, regulation of the exercise. He pointed out the danger incident to injudicious exercise. The amount of exercise to be taken, he said, depended on temperature, pulse rate, respiratory rate, degree of emaciation, existence of complications in heart, kidneys, bladder, intestines etc. Constant temperature above 100 degrees or elevations to this extent in usually afebrile cases, call for absolute rest in bed. Remittent temperature when above 101 in the afternoon, also indicates rest. If the temperature is only 100 the patient may be allowed up, and exercise may be begun when the temperature is below 100 degrees. A pulse rate of 120 in the morning indicates rest. With a pulse rate of 110 or under the patient may sit up, and exercise may be begun when the pulse rate falls below 100 when resting. Breathing rate, he said depends usually on the degree of involvement and the competency of the heart. Marked emaciation contraindicates exercise, even if other signs are favorable. Rest should be insisted on until a satisfactory gain in weight is obtained. The complicating disease should decide the amount of exercise, bearing in mind that rest is even more necessary where two depressing influences are present. He recommended walking as the best and most easily regulated form of exercise. The gait should be slow, and at first the walking should be done only on level ground.

Suppression of Criminal Abortion.

The committee—consisting of Drs. Francis M. Perkins, Charles W. Burr and Henry W. Cattell—appointed by the society to aid in the prosecution of criminal abortionists, reported that thirty cases had been investigated and that each of the thirty persons had either left the city, was under police surveillance, was a fugitive from justice, was awaiting trial, or was in prison. As an additional example of results, it was stated that the Sunday edition of one of the newspapers, formerly carrying from ten to seventeen advertisements of criminal abortionists, no longer printed such material. The hope was expressed that the matter would be taken up by the state society and the American Medical Association. The report has been published in The Journal, Oct. 7, 1905, page 1095.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Asthma.

Kohn, in the *Med. Record*, after a thorough discussion of the disease and its causation, divides the regular methods of treatment into these nine classes: climatic, hygienic, symptomatic, gymnastic, psychic, hydrotherapeutic, medicinal, operative, institutional.

(1) *Climate.*—As a rule, a high altitude relieves asthmatic paroxysms; e. g., there is no doubt that on the high plateaus of New Mexico and Colorado these patients can live comfortably. A small minority of patients seem to get the most relief from the moist air prevailing at the sea shore. Again, some patients are benefited by removal from the city to the suburbs, and others have gained the most relief by removal from the country to the crowded city. An ocean trip has been known entirely to suspend paroxysms in some cases.

(2) *Hygiene.*—This treatment consists in seeing that the functions of the skin and excretory organs are regularly performed; in regulating the metabolic functions; in modifying

the diet according to indications; forbidding overindulgence in food and drink, especially at night, and in interdicting all liquors, heavy wines and champagne. Light alkaline mineral waters like those of Saratoga, and seltzer, vichy, should be used in moderation to keep the renal functions active. The baths of Saratoga or the Virginia Hot Springs, or in Europe those of Kissingen and of Marienbad, are to be recommended.

(3) *Symptomatic Treatment.*—This consists in the indications in each individual case as, for example, in a patient with rheumatic symptoms, we should use the salicylates; in the gouty, colchicum; in the anemic, iron, arsenic, the glycophosphates, etc.; in those of a marked nervous or hysterical disposition, valerian or the valerianates. Uterine, cardiac, renal, traumatic or other cases should be treated accordingly.

(4) *Gymnastics.*—The gymnastic and respiratory, also the pneumatic cabinet and compressed air treatments, have met with considerable favor in Germany, and are best adapted for cases of bronchial asthma in which some lung dilatation has already taken place. The object sought is to prolong expiration. Simple calisthenic exercises and walking long distances in the fresh air have afforded much relief. It is further advocated that the patient be treated by exercises in breathing, which consist in counting slowly during each expiration for five minutes morning and evening. The next day count six, the following day seven, and so on until twenty is counted with each expiration; finally ten minutes mornings and evenings should be consumed in this way.

(5) *Psychic Treatment.*—Brugelmann lays much stress on the value of what he calls "education asthmatique," that is, enlightening the patient on the nature of his disease, and teaching him that by an effort of the will, asthma can be considerably ameliorated, and showing him the necessity of leading a perfectly well regulated life; the importance of proper diet, sufficient sleep, outdoor exercises, principally walking long distances or horseback riding, breathing exercises with inspiration as deep as possible; and of keeping the function of the skin and bowels regulated. There can be no question but that autosuggestion plays a most important rôle in the cure of the disease, as it does in its production.

(6) *Hydrotherapy.*—This is of undoubted value in the treatment of selected cases, especially those of a purely neurotic character without bronchitis; but this method of treatment should be used with great care, because of the sensitive peripheral nerves of these patients and their great reflex irritability. The lukewarm shower daily is recommended, followed by friction with warm towels; douching of the nape of the neck with cool water; when patients can not stand the shower, the lukewarm pack for three or four hours at a time every day, may be tried.

(7) *Medicinal Treatment.*—(a) During the attacks the following narcotics and analgesics may be given to abate it: Opium, morphin, chloral, bromid and phenacetin. In using morphin care must be taken not to establish the habit. Touching the pharynx with a mild solution of ammonia has cut short the asthmatic paroxysm in some cases. A hypodermic of 1/150 of a grain of atropin, the inhalation of a few drops of ether or chloroform, or the burning of stramonium and saltpeter powder, producing a dense smoke, have each been used with success in many cases. Nitrite of sodium, in doses of 2 or 3 grains hourly, has been used with effect, as also the inhalation of a few drops of nitrite of amyl. In some cases the inhalation of pure oxygen gas has proved very beneficial.

(b) Between attacks the treatment by drugs varies according to the individual case and its etiology. Generally speaking, however, the preparations of iodin have the most supporters. The author recommends from his own experience the use of iodid of potassium, begining with 1 grain given in milk three times a day. This dose should be increased daily until the patient takes from 25 to 30 grains a day. It should be noted carefully whether or not the patient bears the drug well. The action of the drug consists in stimulating gland secretion and in lowering arterial pressure. The iodid of sodium or iodid of strontium may be tried when iodid of potassium is not well borne. Atropin has had innumerable advocates as a remedy for asthma; it should be given in increasing doses during the course of disease, as high as from 1/6 to 1/8 grain being given during the twenty-four hours. The other drugs recommended in the treatment are arsenic given in gradually increasing doses, nitroglycerin, quinin, belladonna, iron, strychnin and the other tonics.

The following prescription is recommended for the cough:

℞.	Tincturæ lobeliæ.................m. x		06
	Heroin hydrochloratis.....gr. 1/24-1/12		0027-.0054
	Ammon. muriatis.................*gr. v*		*03*
	Spiritus ætheris comp. q. s. ad........ʒi	4	

M. Sig.: Give this amount at one dose.

Other remedies which have been found of value in the treatment of this condition are 1/1000 solution of adrenalin, which may be given hypodermically in doses of from 3 to 6 minims. Because of the anemic condition of the mucous membranes of the larynx and trachea it has been advised to give large doses of the nitrites.

(8) *Operative Treatment.*—Exaggerated claims have been made for the relief obtained in asthma by operations directed to the nasal passages. It is sufficient to say that the nares should be carefully examined and all growths removed, deformities corrected and hypertrophies reduced.

(9) *Institutional Treatment.*—In Germany this has many advocates; it is claimed that in a sanatorium for asthma, equipped with all the necessary aids to diagnosis and treatment, such as baths, pneumatic cabinets, compressed-air apparatus, gymnastic and electric appliances, and all other necessary instruments of precision, the best results can be achieved, especially when to all of these means is added the constant supervision by physicians who thoroughly understand the disease and its causation. The moral or psychic effect on an asthmatic on entering such a sanatorium with its ironclad rules and regulations and its systematized treatment is excellent; the knowledge that he is under the care of physicians, expert in the treatment of his disease, is in itself apt to have a very salutary effect. In this way autosuggestion plays a great rôle in relieving the patient of his sufferings; and if there is one recommendation that I would make, as a result of my studies on the subject, says Kohn, it is that just as we have sanatoria for nervous diseases or diseases of women, there should be such an institution created for the treatment of this most obstinate and baffling disease.

Medicolegal

Regulation of Employment of Expert Witnesses.

No. 175 of the Public Acts of Michigan of 1905 provides that no expert witness shall be paid or receive as compensation in any given case, for his services as such, a sum in excess of the ordinary witness fees provided by law, unless the court before whom such witness is to appear or has appeared awards a larger sum; and any such witness who shall directly or indirectly receive a larger amount than such award, and any person who shall pay such witness a larger sum than such award, shall be guilty of a misdemeanor, and on conviction thereof shall be punished by a fine not exceeding $1,000, or by imprisonment in the county jail not to exceed one year, or both, in the discretion of the court, and may further be punished for contempt.

No more than three experts shall be allowed to testify on either side as to the same issue in any given case, except in criminal prosecutions for homicide; provided, the court trying such case may in its discretion permit an additional number of witnesses to testify as experts.

In criminal cases for homicide where the issues involve expert knowledge or opinion the court shall appoint one or more suitable disinterested persons, not exceeding three, to investigate such issues and testify at the trial; and the compensation of such person or persons shall be fixed by the court and paid by the county where indictment was found, and the fact that such witness or witnesses have been so appointed shall be made known to the jury. This provision shall not preclude either prosecution or defense from using other expert witnesses at the trial.

This act shall not be applicable to witnesses testifying to the established facts or deductions of science, nor to any other specific facts, but only to witnesses testifying to matters of opinion.

To Promote Anatomic Knowledge.

Chapter 134 of the Laws of North Dakota of 1905 provides that superintendents of penitentiaries, hospitals, insane asylums and poor houses, coroners, sheriffs, jailors, city and county undertakers, and all other state, county, town and city officials who shall have custody of any body, of any deceased person required to be buried at public expense, shall give permission to any physician or surgeon who is a licentiate of the state board of medical examiners, or to any medical school or college, public or private, of any city, town or county within this state, on his or their request therefor, to receive and remove free of charge or expense, after having given proper notice to the relatives or guardians of the deceased, the bodies of such deceased persons to be buried at public expense, to be by him or them used within the state for advancement of anatomic knowledge and medical science, preference being given to medical colleges or schools, public or private; such bodies to be distributed to and among the same equitably; the number assigned to each being in proportion to the students of each college or school; provided, however, that if any person claiming to be, and satisfying the proper authorities that he is of kindred of the deceased, shall ask to have, within thirty-six hours after death, the body for burial, it shall be surrendered for interment; and provided, further, that any medical college or school, public or private, or any officers of the same that shall receive the bodies of deceased persons for the purpose of scientific study under this act, shall furnish the same to students of medicine and surgery who may be under their instruction.

Any physician or surgeon who is a licentiate of the state board of medical examiners, or any medical college or school, public or private, before receiving any dead body or bodies, shall give to the proper authorities, surrendering to him or them a sufficient bond that said bodies shall be used only for the promotion of medical science within this state; and whoever shall use such dead body or bodies for any other purpose, or shall remove the same beyond the limits of this state, and whoever shall buy or sell any such bodies or body, or shall traffic in the same, shall be deemed guilty of a misdemeanor, and shall, on conviction thereof, be fined in the sum of $100, and any officer refusing to deliver the remains or body of any deceased person, when demanded under the provisions of this act, shall be guilty of a misdemeanor and shall pay a fine of not less than $50.

It shall be the duty of preceptors, professors and teachers, and all officers of medical colleges and schools, public and private, and all others who shall receive any dead body or bodies in pursuance of the provisions of this act, decently to bury in some public cemetery or to cremate the same in a furnace properly constructed for that purpose, after the bodies shall have answered the purposes aforesaid, and for any neglect or violations of the provisions of this act the party or parties so neglecting shall be guilty of a misdemeanor, and on conviction shall pay a penalty of $100.

Pure Drug Law.

Chapter 10 of the Laws of North Dakota of 1905 provides, under penalty, that it shall be unlawful for any person, his agent or servant, or while acting as agent or servant of any other person or corporation, to manufacture for sale, offer for sale, or sell within this state any drug which is adulterated within the meaning of this act. The term "drug" as used in this act shall include all medicines for internal and external use, antiseptics, disinfectants and cosmetics.

A drug shall be deemed to be adulterated: First—If, when sold under or by a name recognized in the United States Pharmacopeia, it differs from the standard of strength, quality or purity prescribed therein, unless the order therefor requires an article inferior to such standard, or unless such difference is made known or so appears to the purchaser at the time of the sale. Second—If, when sold under or by a name not recognized in the United States Pharmacopeia, but which is found in some other pharmacopeia or other standard work on materia medica, it differs materially from the standard of strength, quality or purity prescribed in such work. Third—If its strength, quality or purity falls below the professed standard under which it is sold; provided, that a drug or medicine shall not be deemed adulterated in the following case: If the standard of strength or purity of any drug has been raised since the issue of the last edition of the United States Pharmacopeia, no prosecution relative to it shall be maintained until such change of standard has been published throughout the commonwealth.

Every proprietary product, drug, medicine or beverage containing more than 5 per cent. of ethyl alcohol, or which contains chloral hydrate, ergot, morphin, opium or any of their compounds or derivatives, cocain or any of its salts, bromin, iodin or any of their salts, shall be clearly labeled in black open gothic letters, printed on a white background, showing the name and percentage of each of the foregoing constituents, and said label shall be affixed to each and every package, carton, box or bottle in such a way as to be clearly seen.

No sale or gift of cocain or of its salts shall be made, or delivery thereof made in this state, except on the written prescription of a licensed physician.

It shall be unlawful to sell, offer or expose for sale, or have in possession any preparation or product, intended for the use of man, either for internal or external purposes, which contains methyl alcohol or "wood spirits."

Nothing in this act shall be so construed as to in any way interfere with the written prescription of any regularly licensed physician or with the filling of the same by a licensed druggist.

The North Dakota government agricultural experiment station shall make analysis of drugs and medicines found on sale in North Dakota suspected of being adulterated, at such times and places, and to such extent as it may determine, and may appoint such agent or agents as it may deem necessary for the enforcement of the provisions of this act, and such agent or agents shall have free access and egress, at all reasonable hours, for the purpose of examining into any place wherein it is suspected any drug or medicine adulterated with any deleterious or foreign ingredient or which falls below the standard of purity or where such ingredients exist, and such agent or agents, on tendering the market price of said article, may take from any person, firm or corporation samples of any articles suspected of being adulterated as aforesaid. Whenever said station shall find, by its analysis, that adulterated drugs have been on sale in this state, or that said drugs are in violation of this act, it shall forthwith transmit the facts so found to the attorney general and the state's attorney of the county in which said adulterated product was found.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

1. *Scopolamin-Morphin Anesthesia.*—Wood epitomizes his personal experience with scopolamin-morphin anesthesia as follows: It is capable, in many cases, of producing a satisfactory surgical narcosis lasting several hours. When successful, the patient avoids the anxiety or even alarm often felt before taking ether, and the nausea, vomiting, and depression following its administration. If it should partly or wholly fail to anesthetize the patient, the surgeon may use

ether or chloroform, with the assurance that the effect will be more prompt and satisfactory than when either is administered alone. When used in conjunction with ether or chloroform, it has been especially satisfactory. The time required to induce anesthesia was lessened, relaxation promoted, the secretion of mucus in the respiratory tract prevented, and, what is very important, the quantity of anesthetic required was greatly reduced. To induce full anesthesia in the average healthy adult, Wood recommends 0.0006 gm. (1/100 gr.) scopolamin and 0.01 gm. (1/6 gr.) morphin, to be given hypodermically two or two and a half hours before operation, and a second similar dose an hour later. If the anesthesia is not sufficiently complete half an hour before operation, a third dose may be given. This may be the same as the two previous doses, or may consist of either drug alone, or of scopolamin in conjunction with apomorphin, according to the special indications present. The doses should be considerably reduced in children, feeble patients, and in advanced age. None of Wood's patients remembered feeling any pain, or any other detail of the operation, although in some instances the patient gave evidences of the presence of sensation at the time. This preparation is contraindicated in acute affections of the pharynx and larynx; in operations involving the mouth or air passages; in edema of the lungs, and in cases in which capillary hemorrhage may be a troublesome factor. As both scopolamin and morphin are powerful drugs, prudence demands that they be used with caution. In addition to the caution mentioned, the safety and success of the method depend on having pure and reliable drugs, accurate dosage, and perfectly fresh solutions.

2. **Importance of Study of Nutrition.**—Chittenden says that physicians should have a full and complete knowledge of the various processes of nutrition so that they may be able to correct those deviations from the normal which are characterized as disease. There can be no exaggeration in emphasizing the importance of the *daily* diet in the *maintenance* of health and in the establishment of a proper and normal condition of nutrition. Prevention is better than cure, and, says Chittenden, we may well ask whether, with a proper understanding of the true laws of nutrition, of the real needs of the body for food, with a clear conception of the processes of digestion, secretion, absorption, peristalsis, circulation, and excretion, we should not be in a better condition to combat disease than we now are. In his opinion, two, at least, of the dread diseases of mankind, namely, cancer and tuberculosis, are possibly connected with a disturbance of nutrition in which, perhaps, the predisposing causes are to be found in an excess of nutritive material, in general, in the blood, or to a disturbance in the balance of nutritive materials between the circulating medium or possibly in the tissues themselves. Chittenden believes that there is much of value to be learned in a study of the minimum quantities of food required to maintain health and strength, because the real needs of the body for food are unquestionably very much below the amount ordinarily consumed, and, this being true, is it not possible that this excess of food, for which the body has no physiologic need, in the long run imperils the health of the individual, diminishes the ordinary powers of resistance, and so paves the way for various forms of disordered nutrition spoken of as disease.

3. **Animal and Vegetable Dietaries.**—Mendel contrasts the relative values of animal and vegetable dietaries. He says that vegetarianism undoubtedly has its place in ameliorating various functional disorders. In the treatment of obesity, certain forms of neuralgia of unknown origin, and of gout in many instances, the strict diet renders effective aid. In estimating food values, not only the composition of the food, but also the degree of its utilization in the alimentary tract must be considered. No exclusive system of diet deserves defense on scientific ground.

5. **Study of Freezing Point of Blood and Urine.**—Tieken reports the results of his observations of the freezing point of blood and urine in surgical diseases of the kidneys and of the urinary tract. His conclusions regarding the value of cryoscopic examination of the blood and urine in surgical diseases of the kidneys coincide with those of Kümmel, Rumpel and others, namely, that it is of value in this class of cases, because it shows whether or not the remaining organ is competent. In diabetes mellitus, of a severe type, he usually finds a concentration of both the blood and urine, but the percentage of sugar in the urine bears no constant relationship to the freezing point, as claimed by some recent writers. He was unable to demonstrate a molecular concentration of the blood in abdominal tumors not of renal origin, unless great pressure was exerted, disturbing the renal function. Tieken thinks that cryoscopy, when employed with a thorough understanding of its limitations and possibilities, may be of conceivable value to both the physician and surgeon, as a diagnostic and prognostic aid, in certain pathologic conditions.

7. **Sea Air Treatment of Tuberculosis in Children.**—Brannan details the excellent results achieved in the treatment of children suffering from tuberculosis of the bones and glands at the Summer Home on Coney Island.

8. **Influence of Climate in Pulmonary Tuberculosis.**—This committee states that if we look for the causes of the tendency to doubt the value of climate in the treatment of tuberculosis they are to be found, first, in the unskillful use in the past of climate as a therapeutic measure; second, in the formerly widely spread belief in a mysterious specific influence of climate which led to a superstitious faith in its unaided powers and, therefore, to a neglect of those even more important matters, hygiene, diet, instruction and detailed supervision; third, in a lack of appreciation of what the climate has been doing for them all the time. Realizing, then, as we now do, that the very first aim in the treatment of tuberculosis is and must always remain the raising of the vitality of the patient's system until it is able itself to conquer its disease, we see that the beneficial effect of climate depends on its wonderful power in vitalizing the system, on its beneficial effects on metabolism, on its awakening of dormant or waning natural powers. No advanced workers in this line would to-day, as was formerly done, place climate first in the order of therapeutic measures. Let it never be forgotten that hygiene, diet, *teaching and supervision must always come first, but, granted that* they are properly attended to, then enters the powerful rôle of climate, reinforcing and accentuating the effects of these other measures, and yielding results that can not be approached even with the same care and watching and food in less favorable localities. The elements in climate which have a beneficial influence are, in the order of their importance, (1) an abundance of chemically and bacteriologically pure fresh air; (2) sunshine; (3) coolness, or, in a certain number of cases, warmth; (4) dryness, or, in a few cases, a moderate degree of humidity; (5) altitude; (6) wind to which the patient is not directly subjected, provided vegetation is sufficient to prevent dust storms, is beneficial; (7) equability; (8) proper soil. Brannan says that a climatic resort should be looked on as a university to which the patient goes to get under proper conditions that discipline and instruction which he will bring back with him into his daily life at home, where he should serve as a teacher of those with whom he is thrown. The physician in a climatic resort will be of use to his patient in proportion as he is able to be a forceful and stimulating teacher.

17 Transverse Incision in Abdominal Operations. A. E. Rockey, Portland, Ore.

13. **Non-operative Gynecology.**—McNutt maintains that in many instances a woman with pelvic or abdominal disease may recover under medical treatment only, without operation. The cases calling most urgently for operative treatment are those of pelvic or abdominal tumor, the accidents of childbirth, malignant disease, and pus collections. In order to deal successfully with the non-operative cases it must be remembered that many of the symptoms present are reflex in origin. Hence, the treatment must be general as well as local. The most frequent general symptoms are the derangements of secretion and excretion, anemia and nervous symptoms. The most frequent local conditions are (1) displacements of the uterus, with or without displacements of the adnexa; (2) catarrhs, acute, subacute, and chronic, confined to the uterus; (3) the same, with extension to the tubes and secondary involvement of the ovaries. In many cases one can use local treatment indefinitely and utterly fail to cure the patient if with it does not go general medication and hygiene. This includes diet, clothing (few women dress properly), and carefully regulated out-of-door life, with some interest to divert the mind from introspection.

14. **Non-gonorrheal Urethritis.**—In view of the fact that the causes contributing to the production of urethritis are so numerous as to be beyond comprehension, Spooner prefers a classification based on the clinical conditions in which cases of non-gonorrheal urethritis have been observed. He suggests the following classification: (1) Urethritis caused by external irritation: Coitus, catheterism, ungratified erections (?) masturbation (?), medicated injections. (2) Urethritis caused by internal irritation, mechanical, chemical, and tonic, of constitutional origin: Food, drinks, drugs, gout (?), rheumatism (?), arthritic diathesis (?), diabetes (?), herpes, mumps (?), syphilis (?), tuberculosis, typhoid fever (?). From the clinical point of view differential diagnosis is impossible, but, as a rule, in non-gonorrheal urethritis the incubation period and the course are shorter and less painful than in the specific form. Non-gonorrheal urethritis of constitutional origin must be treated so as to remove the exciting cause. When due to pyogenic bacteria the treatment is the same as in gonorrheal urethritis. Some cases of aseptic urethritis of unknown origin are not influenced by any form of treatment.

15. **The Stomach in Pulmonary Tuberculosis.**—Palier has studied the gastric conditions present in a number of cases of pulmonary tuberculosis, most of the patients being men between the ages of 22 and 45. He describes several of these, and says that his observations lead him to believe that in about 60 per cent. of the cases of incipient consumption there is hyperchlorhydria, in 20 per cent. the stomach is about normal, and in about 20 per cent. there is hypochlorhydria. The diet, therefore, must vary in different cases of the disease, and it is necessary to study the condition of the patient's stomach before it is possible to lay down rules for his nutrition. The stomach tube is not likely to do harm if carefully used. The effect of gastric juice in the tubercle bacilli in the sputum swallowed was also investigated. It appears that the normal gastric juice is bacteriolytic to the tubercle bacilli, but *in vitro* the process is very slow. The author believes, however, that in the stomach it is much more active, so that ordinarily no bacilli can pass the normal stomach and reach the intestine in virulent condition. In hypochlorhydria they undoubtedly can, and also under any conditions on repeated ingestion some may find opportunities to slip through and to cause disease. The frequency of hyperchlorhydria with hypersecretion in pulmonary tuberculosis, the author believes, explains the frequency of gastric ulcer in this disease.

16. **Treatment of Perforations of the Tympanum.**—Yates recommends the use of patches of rubber to be applied over the perforation, so as to make an air-tight joint, in the treatment of recent or long-standing cases of this injury. In applying a patch to the drum a piece of rubber is selected, which is about twice the size of the hole to be covered. The canal and drum are thoroughly sterilized by syringing and mopping, and dried. If necessary, the edges of the perforation are pared or touched with nitrate of silver. The disc is carried into the drum by means of forceps or a cotton-tipped probe through a speculum, if small, without it if too large. It is then pushed into position and the edges pressed down firmly all around. No adhesive material is necessary. The rubber is most conveniently sterilized by keeping it in alcohol or other antiseptic for a few moments while other preparations are being made. The patch hastens the reparative process and at the same time effects an immediate improvement in the hearing. Yates sums up the advantages of rubber tissue used in this way as follows: (1) It is convenient, easily sterilized and applied. (2) It is flexible, remains in place for a long time, and requires no adhesive material. (3) In large perforations it has the advantage over the various forms of artificial ear drums in not causing pain or irritation or setting up a discharge. It helps to heal at the same time that hearing is being improved. (4) Healing is rapid and the formation of scar tissue, which is likely later to give way or to become the seat of calcareous deposits, is reduced to a minimum.

18 *President's Address Before the American Hospital Superintendent's Association. G. H. M. Rowe, Boston.

19 *Observations on the Comparative Value of Different Methods of Applying Plaster Jackets in Spinal Caries. E. G. Brackett and L. R. G. Crandon, Boston.

20 *Treatment of Chronic Prostatic Enlargement. J. P. Lewis, Boston.

18. **American Hospitals.**—In this address Rowe details much of interest to hospital superintendents, as well as to the general profession. According to his statistics, New York has the largest number of public hospitals; Pennsylvania is second; Illinois third; Massachusetts fourth, and California fifth. Nevada is the only state which has no hospital, either public, private or ecclesiastical. New York also leads in the number of private or corporation hospitals. Illinois leads in the number of ecclesiastical hospitals. Of the total number of hospitals in this country, 220 are public, 442 are ecclesiastical and 831 are private institutions. Training schools for nurses are maintained by 867 hospitals. The ratio of training schools among the states is much the same as the number of hospitals. Oklahoma is the only state or territory that has no training school for nurses. The number of patients treated during the year was 1,064,512, 20 per cent. of these entering the hospitals of the State of New York; Pennsylvania comes next with 10 per cent., Illinois with 8 per cent., and Massachusetts with 4 per cent. Rowe believes that if large hospitals must increase their bed capacity it should be done by establishing branch hospitals somewhere outside the crowded city, but easy of access. The branch hospital should be used for emergency work and the main hospital for the treatment of general cases. He also advocated better utilization of the hospital for teaching purposes.

19. **Value of Plaster Jackets.**—Brackett and Crandon record the results of their observations made for the purpose of comparing the various methods of applying plaster jackets with reference to their use in various regions of the spine; to ascertain whether or not there resulted any attendant evils, immediate or remote, from the attempt to obtain the greatest possible correction; to test the fork apparatus, and to determine a way of estimating the weight of the finished jacket at the time of its application, as well as the minimum weight for a durable jacket. They found that lumbar disease improves under any method, but with the balance in favor of the hammock. Dorsolumbar and dorsal disease shows a gradual increase by any method of extension that brings about a compensatory increase of the normal lumbar curve. In disease involving the fourth dorsal vertebra (high dorsal) the spine may be held erect by either form of dorsal support, provided the jacket is carried high in front. Care is necessary, however, to avoid postural defects. The ventral position is adapted for all cases of lumbar disease. It is also applicable to dorsal cases, in which the portion covering the anterior chest is left until the patient is removed from the hammock, and the jacket finished in the sitting posture, with the patient held back in the extended position. The dorsal position is adapted to disease in either the lumbar or dorsal regions, but particularly to the dorsal. The fork is rather the more applicable to the dorsolumbar and lower dorsal, and the rods to the higher dorsal cases. In the old cases with deformity care must be taken

to avoid lordosis. The control of this by the flexed thighs is more apparent than real. The poise or balance in the standing position after the application of the jacket is a valuable guide and should be taken into account. The most accurate way of estimating the weight of the finished jacket is by the weight of the rolls before wetting. The shrinkage in weight is equal to about 9 per cent. of the rolls before wetting. A jacket of about 1 pound 12-14 ounces should be sufficient for a child of from 3 to 5 years of age, and a jacket of 2 pounds 10 ounces' weight sufficient for a child of from 10 to 12 years.

20. **Treatment of Chronic Prostatic Enlargement.**—Lewis presents the following conclusions: 1. The use of sounds is generally to be condemned. 2. The sphere of usefulness of the catheter is growing smaller and smaller as the advantages of an early operation make themselves manifest. 3. The Bottini operation may be applicable in selected cases, but should seldom, if ever, be adopted. 4. Orchidectomy, vasectomy, ligation of the internal iliacs, injection of carbolic acid, application of electricity and allied methods, he says, are to be condemned. 5. Prostatectomy is the procedure of choice, best performed when the symptoms first make themselves manifest and the patient's condition is presumably at its best. 6. The preferable route is through the perineum, the preferable method that of Young or one of its modifications, but much depends on the skill of the operator in the method employed. 7. In patients with foul bladders and diseased kidneys who, we have reason to expect, would not stand an extensive operation, thorough drainage should first be instituted either by a suprapubic or perineal incision under local anesthesia, to be followed later by enucleation, if deemed advisable. 8. The use of local anesthesia, especially spinal cocainization, is of great value, and should be more extensively employed.

26 Chronic Headache and Its Treatment by Massage. (Continued). G. Norstrom, New York.
27 *Talma's Operation. G. C. Stemen, Denver, Colo.

23. **Cesarean Section for Puerperal Convulsions.**—The indications for operation in this case, reported by Woodbury, were the urgent necessity of emptying the uterus of its living contents on account of puerperal convulsions with rigid os after two failures of delivery by forceps. Version was regarded as being contraindicated by the absence of amniotic fluid and the inertia of the uterine muscle. The section was performed after Saenger's method, and a living child was extracted. The uterus was closed with interrupted sutures of catgut prepared by the Claudius method; the peritoneum and fascia were brought together with continuous sutures of the same and the skin with interrupted sutures of silkworm gut. The patient rallied well from the operation, but on the seventh day the temperature rose rapidly, and in spite of all efforts she rapidly grew weaker and died in coma.

24. **Roentgen Ray in Leukemia.**—A study of the literature by Holding and Warren shows that 25 cases with splenomyelogenous leukemia treated by the *x*-rays have been reported; 15 were improved; in 2 cases there was no improvement or the cases terminated fatally. Second, 8 cases of patients with lymphatic leukemia treated by the *x*-rays have been reported; no patients were cured; three were improved; and in five cases there was either no improvement or a fatal termination. Third, 22 cases of patients with pseudo-leukemia similarly treated have been reported; 6 were symptomatically cured; 13 were improved, while in 3 cases the condition was either unimproved or the case terminated fatally. Two cases are reported by the authors, and attention is directed to the following points: First, the marked action which the *x*-rays have on the lymphatic system and blood-making organs; second, its palliative action in cases of leukemia and pseudoleukemia, and to suggest that in some cases even curative effects may be hoped for; third, further observation of the action of the *x*-rays in this class of diseases is recommended.

25. **Ocular Symptoms of Gout.**—Wheelock reports four cases in which the ocular evidence of gout was followed by local manifestations of undoubted character. The following tissues of the eye are known to be affected by gout: Iris, choroid, sclera, retina and lens. Among the conditions observed are the following: Iritis, plastic and serous; cyclitis, plastic and serous; choroiditis, retinitis, retrobulbar neuritis, scleritis and episcleritis; cataract; hemorrhagic retinitis and glaucoma. Wheelock has observed all these conditions, except involvement of the lens, and has felt certain that the origin was gouty, yet in many cases, the evidence followed the administration of colchicum and potassium iodid. He also recognized gout as the causative factor in several forms of keratitis.

27. **Successful Talma Operation.**—Stemen operated on his patient in November, 1904, employing the method advocated by Talma as nearly as possible. There have been no unfavorable symptoms since the operation. The patient has gained in weight; his nutrition is good and there has been no ascites nor any evidence of a return of the original condition.

33. **Effect of Diet Cures in Diabetes.**—Friedenwald and Rubräh bring forward certain diet cures which have assumed some importance during the past few years, such as the milk cure, the potato cure, and the oatmeal cure. Their observations with the use of milk as a form of diet in diabetes are in accord with those of von Noorden. They have rarely found it advisable to place any of their patients on an exclusive milk diet, except in those severe cases of diabetes in which diacetic acid is present in the urine and in which the patient is threatened with the onset of diabetic coma or in which this condition had already set in. On the other hand, they have utilized from one-half to a liter of milk daily in many of their cases of diabetes in addition to other allowable foods, often with excellent result. They have never followed Mosse's plan, that of replacing all carbohydrates by potatoes, but have rather followed the method suggested by von Noorden, that of replacing a portion of the bread by this form of food. A patient who is permitted to consume 100 grams of bread a day can take 300 grams of potatoes, so that at least a certain proportion of the bread can be replaced by this form of food. They have never seen the slightest harmful effect produced by the use of potatoes, even in severe forms of diabetes. In a not inconsiderable number of cases very beneficial results were obtained. The potato has an additional advantage, in that it lends variety in furnishing carbohydrate food as it can be prepared in various ways, and again as being a means to which fatty food, such as butter, can be furnished the body in large quantities. The oatmeal cure

was found especially useful in those forms of diabetes exhibiting diacetic acid in the urine. In the mild forms it is not only a useless treatment, but may even prove harmful. In the severe forms of diabetes remarkable results have been obtained with the oatmeal cure. The authors believe that these cures are valuable aids in the treatment of diabetes, but urge that great care must be practiced with the use of these various forms of diet. Each case must be studied individually and must be watched carefully in order to obtain the best results.

35. **Treatment of Acute Rheumatic Endocarditis.**—Robinson has found that no antirheumatic remedy is so useful and so free from objections as salicin. Salicin has been given in doses of 30 grains every hour for eight doses, and subsequently in 20 grain doses every two hours for one or several days, without occasioning appreciable accidents of any kind, and apparently with only relief to the patient's symptoms and general condition. It does not produce any headache or nausea. By the use of salicin the poison of rheumatism may be neutralized, the disease shortened, and thus there is less likelihood of having endocarditis appear. If the endocarditis exists already, it is advisable to continue the salicin to prevent further cardiac complications. In cases of subacute and chronic rheumatism, in which Robinson has given salicin many times in small or moderate doses, more or less frequently, he has repeatedly known symptoms to disappear completely or be much ameliorated in a few days or weeks, and without any intercurrent manifestations of an unfavorable nature which could be attributed to its use. Robinson cautions against interrupting the treatment too soon or reducing the amount of the drug too rapidly. In the case of children, when the heart becomes involved, Robinson has found it preferable to administer salicin, because it is a safer remedy than salicylate of soda.

37. **Case of Metastatic Endothelioma.**—Wood reports the case of a man, aged 43, whose family and personal history was negative, who four years ago noticed a small nodular mass on the surface of the right testicle. The testicle became painful and began to increase in size; it was firm in consistence and showed no sign of breaking down in any part of it. This condition gradually increased until the final removal of the testicle in the same year. Two years later the left testicle became similarly affected and was also removed. In both instances a diagnosis of sarcoma was made, which was confirmed microscopically. In 1904, following a fall, the patient began to complain of backache. This pain persisted with intervals of comparative freedom, followed by exacerbations which would necessitate remaining in bed several days at a time. During this time the man kept his full weight and showed no signs of cachexia. All the organs were normal, except the left kidney, which could not be palpated in its normal position. The provisional diagnosis was made of malignant disease of the left kidney. An exploratory incision revealed a kidney enlarged to about three times the normal size, and placed almost transversely across the abdomen. A nephrectomy being found impracticable, nothing more was done. A few days later the right leg was considerably edematous. It gave the patient some discomfort, though it was not acutely painful. The edema soon extended to the scrotum. Ten days after the operation the patient was seized with pain in the side and became cynosed. He began to have a prune juice expectoration, developed a temperature, and finally became delirious. Twenty hours later he died with a large pulmonary hemorrhage. Tumors were found in the kidney, liver and lung. Microscopic examination showed these tumors to be endotheliomas. Wood concludes that the tumor of the testicle was unquestionably a large, round-cell sarcoma and that this was the original source of the disease. This being the case, and the metastatic tumors being of the endothelial variety, it may be taken as evidence that endothelioma is a sarcomatous tumor. It is notable in this case that the metastasis was exceedingly slow for a sarcoma, nearly five years elapsing from the time of invasion to death.

40. **Permeability of Rubber Gloves to Bacteria.**—Fox and Schumann selected at random from a lot purchased for hospital use six pairs of rubber gloves and subjected them to experiments which showed conclusively whether or not the rubber glove is an absolute safeguard against the implantation of bacteria from the hands of the surgeon to the field of operation. The results of these experiments were such as to justify the authors in arriving at the conclusion that rubber gloves are absolute barriers against wound infection by the hands of the surgeon in so far that they are absolutely bacteria proof. Any infection occurring must be introduced into the wound from some point not protected by a glove.

42. **Brachial Birth Palsy.**—Clark, Taylor and Prout's research embodies new facts in the etiology and pathology of the laceration type of birth palsy, the development of the relationship thereto of the symptomatology, and the establishment of a scientific basis for treatment. They found that the cause of the laceration type of birth palsy is tension on the nerve trunks, which first ruptures the nerve sheath and then the nerve fibers. The prevention of this serious lesion of the cervical nerve trunks rests with the obstetrician, who should not overstretch the child's neck in the process of delivery. The persistence of the palsy is clearly explained by the pathologic findings, viz.: (*a*) Rupture of the perineurial sheath with hemorrhage into its substance, resulting in the formation of hematomata or hematomatous infiltration into the neighboring tissues. (*b*) The cicatricial contraction following organization of the blood clot and repair of the rent in the perineurial sheath. The connective tissue thus formed indents and presses on the nerve bundles, strangulating them and preventing regeneration of the nerve fibers. In some instances the same result is accomplished by turning inward of the perineurial sheath on the nerve bundles. The nature of the lesion in all cases demands excision of the damaged areas and suture of the divided ends as soon as it is proved that spontaneous repair will not take place. The plan of treatment is then the same as that for peripheral nerve injuries elsewhere. In all cases, such treatment as will prevent contractures and deformities and maintain muscle tone in the paralyzed limb should be systematically used until either spontaneous recovery occurs or operation is done. (Traumatic neuritis is a contraindication to active treatment.) It is obvious that the above measures should be continued after operation. The proper time for surgical interference is not yet definitely fixed. It appears, however, to be much later than two or three months after birth. At the present time one year would seem to be a reasonable delay before operation.

46. **Surgical Treatment of Bleeding Gastric Ulcer.**—Beck formulates the indications for a surgical procedure in hemorrhage as follows: A first hemorrhage in a previously healthy individual, while in most cases healing by medical treatment, requires careful watching; if prolonged and if the pulse indicates an arterial hemorrhage, it must be treated surgically. A first hemorrhage in a previously suffering patient, if profuse or prolonged, ought to be treated surgically at once or shortly after the patient recuperates, as the ulcer will keep on bleeding and certainly will invite complications. A continuous slight bleeding with marked influence on the patient, such as anemia, weakness etc., is a clear indication for surgical interference. The operation of choice ought to be excision with or without gastroplasty.

55 After-Treatment of Operative Cases. E. Martin, Philadelphia.

53. Permanency of Results in Tuberculosis.—Pottenger reports the after history of 27 patients with pulmonary tuberculosis, treated in office practice. No single remedy or measure was relied on, but everything was used that could be of any benefit to the patient. Twenty-five patients improved. Twenty patients are apparently cured and are now enjoying good health. In not one instance has there been a relapse although six years have elapsed since the first patient was discharged, and 26 months since the last patient was discharged. Seven patients are classed as improved. Of these, all are dead but one. Two of these cases were hopeless from the start, as the patients were suffering from acute tuberculosis, and in another case, which was never hopeful, the patient developed acute tuberculosis within six months after stopping treatment. The other three cases followed the natural course of chronic tuberculosis. Pottenger believes that it is just as possible to obtain a permanent cure in tuberculosis as in any other disease.

2. Addison's Disease.—Bramwell reports a case of Addison's disease which improved remarkably under the open-air treatment and the simultaneous administration of suprarenal extract. The patient, a man, aged 36, had been ill for eighteen months. He applied for treatment early in November, the weather at the time being cold, wet and stormy. The man was placed on the balcony outside the hospital ward and stood the exposure well. The suprarenal extract was administered in 5-grain doses three times daily. All the symptoms disappeared rapidly and the patient was discharged as cured five and one-half months after the beginning of the treatment. Death occurred suddenly two years afterward, due to asthenia and failure of the heart action, probably from autointoxication. A postmortem examination was not held.

3. Tumor of the Spinal Cord.—Following a fall, Ward's patient developed a marked spastic paraplegia, with no voluntary control of any muscle in either lower limb. A diagnosis was made of the tumor and an operation was advised. The spines and laminæ of the ninth and tenth dorsal vertebræ were separated with saw and bone forceps, and as soon as they were removed the dura mater bulged through the opening. It looked like a cyst filled with transparent fluid, through which the posterior surface of the cord could be dimly seen. On palpating the cord a tumor could be felt almost entirely filling the canal. The dura mater was incised, and immediately fluid under great pressure bulged out, and the posterior roots protruded through the opening thus made; when the first gush of fluid had lessened fluid was also seen to be spurting out in a tiny stream from between the strands of the posterior roots: no tumor was to be seen, but it could be felt as a distinctly localized growth about the size of a walnut, quite hard, covered in by the posterior roots which were stretched over it, and situated somewhat more on the right side than the left, the cord itself was not to be seen, being completely covered in by the roots. The strands of these roots were carefully separated with a director and the tumor exposed; it was then shelled out quite easily by curving the director and passing it round the tumor in all directions, care being taken to keep it pressed against the tumor so that no damage should be done to the cord. Free oozing followed and immediately filled the cavity from which the growth had been removed, so that the cord itself could not be seen, and as the patient was rather collapsed, no time was wasted in examining the cavity, but owing to the size of the tumor the cord could not have been much thicker than a piece of ribbon. The dura mater was closed by a continuous fine catgut suture, and the wound closed except for a drainage tube. The wound healed by first intention, but there was a discharge of cerebrospinal fluid from the drainage tube hole for three weeks afterward. At first this was very profuse, soaking the dressings through in a few hours, but gradually lessened. Except for the relief of distressing pain in the back, the patient's condition remained practically the same until his death, twenty months later, from extensive bedsores. The tumor was a fibrosarcoma weighing 75 gr. and it had evidently grown from the posterior root sheaths.

4. **Heredity and Disease.**—Mott discusses at length the relationship of heredity to disease, and cites a number of well-known instances, such as Sanger Brown's family of hereditary ataxia, hereditary hemophilia and hereditary Daltonism. A study of statistics relating to the birth and death rate of tabetic and "tabo-paralytic" patients showed the following: Twenty-two married women suffering with tabes or tabo-paralysis had 38 children. Ten are still alive; 10 died in infancy or later; 18 were born dead. These women had 31 miscarriages. Of 54 married men, 151 children are living; 75 died in infancy or later, and 52 were born dead or were miscarriages. Mott says that there is no lack of fertility or fecundity on the part of the male parasyphilitics, but the death rate of offspring is higher than the normal average. The female parasyphilitics, however, show a very high death rate, lack of fertility and sterility. Over 30 per cent. are absolutely sterile and never conceive. In 32 pregnancies in which the father suffered from lead poisoning, the mother being free from that condition, 12 resulted in the death of the infants before term. Twenty children were born alive, but all except 2 died before the fourth year of life. This study shows that not only can lead produce abortions and miscarriages in females, but that male workers in lead, suffering with lead poisoning, have devitalized offspring which either die *in utero* or survive only a short time after birth. As to alcohol, Mott says that it is assumed that alcoholism is a potent factor in the production of mental and physical degeneracy of the offspring, but there are no certain data to show whether the transmission to the offspring is the inherent defect of control, vicious temperament, or the unbalanced mind which led to the drunkenness of the parent or parents, or a defect induced by the poison. Probably there is a transmitted mental defect increased by the poison, fixed and made permanent by the force of imitation. Drunkenness in several generations of the same family may be the result of several factors, and it goes on until regression to the normal by conjugation with a healthy stock occurs, or terminates by degeneration and elimination of the stock. Mott is strongly of the opinion that alcohol is a poison to all neuropathic stocks. Tuberculosis and degeneracy, nervous and mental diseases, and hereditary tendency to suicide are also discussed.

9. **Relation of Cells to Cancer.**—Ross believes that the genesis of cancer and of all malignant growths appears to be a question of alteration of cell polarity, and, therefore, work on cancer research should consider cell polarity in all its bearings.

10. **Feces in Diagnosis.**—Cammidge suggests that a chemical examination of the feces may often be of assistance in arriving at a correct diagnosis in cases of jaundice or suspected pancreatic disease. When the analysis is carefully performed by a competent and experienced observer, the results, considered in conjunction with the clinical symptoms, are of inestimable value.

11. **Rapid Estimation of Uric Acid.**—The method devised by Dimmock and Branson consists in taking 100 c.c. of urine and adding to it 1 gram of lithium carbonate (L_2CO_3) after boiling in a conical flask (Erlenmeyer) of about 100 c.c. capacity for three minutes, the liquid is filtered while hot to remove the precipitated earthy phosphate, etc., which are washed with a little distilled water until the filtrate measures exactly 100 c.c. To 50 c.c. of the filtrate, which contains uric acid as lithium urate, 5 grams of ammonium chlorid are added, shaking the liquid until dissolved. After three minutes the contents of the flask are warmed to 120 F., so as to secure a uniform aggregation of the precipitated ammonium urate. The whole is now poured into a tube graduated in parts per thousand of uric acid, and deposition allowed to take place, the reading being taken after four hours have elapsed.

13. **Caffein Enrichment Method.**—Birt found that 0.5 per cent. caffein in 1 per cent. peptone water does not always restrain the development of the *Bacillus coli communis;* that 0.5 per cent. caffein in 1 per cent. peptone water inhibited the growth of 26 out of 31 races of *Bacillus typhi abdominalis* examined; that 0.5 per cent. caffein in 1 per cent. peptone water completely arrested the development of 18 varieties of dysentery bacillus; that caffeinated media are of service in isolating streptococci and staphylococci; that negative results with caffeinated media can not be relied on to exclude the presence of *Bacillus typhi abdominalis* in water or dejecta.

15. **Influence of Bacteria on Bone Marrow.**—In the course of observations made by Jones with a view to determining the influence of micro-organisms on the cellular constituents of bone marrow, he found: (a) That different micro-organisms bring about different types of bone marrow; (b) that this depends not only on the virulence, but on the specificity of the organism; (c) that apparently a lymphoblastic marrow is usually associated with an increased production of erythroblasts; (d) that a leucoblastic marrow, on the contrary, is not connected with an increased erythroblast production.

19. **Membranous Colitis.**—White reports the history of 60 cases observed by him. Fifty-one patients were women and 9 were men. Forty-nine of these cases occurred between the ages of 20 and 50, the fourth decade claiming the largest number, 22. The youngest patient was under 10 years and the oldest over 70. Eight of these cases were fatal. In 16 cases complete recovery did not take place, although they were not fatal; 6 patients were much improved, and 21 made complete recovery. White lays great stress on the association of membranous colitis with disorders of the female generative organs. In about 41 per cent. of his female patients such an association existed. White says that by far the most important part of the treatment is to keep the large bowel empty. The simplest way to do this is by aperients and in many cases castor oil by the mouth will cure the patient. The best time to give this is the early morning as soon as the patient wakes; then the bowels are usually comfortably opened after breakfast. Many people wake an hour or two before they get up, so the oil should be taken then. Between half an ounce and an ounce is usually required. If the disease has lasted some time many weeks, even up to twelve or sixteen, may be needed before improvement is observed; the treatmnt should never be given up until a long trial has been allowed to it, and in all cases it should be continued for some months after apparent recovery. A minority are so nauseated by castor oil, however given, that they can not take it; in such cases sulphate of magnesium should be tried instead, or if this be found unsuit-

able calomel should be given over night. Should these methods fail the large intestine should be kept empty by washing out with plain water at a temperature of 100 F., a pint or more being used at a time. Operation should not be resorted to except in desperate cases.

25. **Plaster-of-Paris Splints.**—In order to overcome the objections made to plaster casts applied in the treatment of fractures, Wilkinson uses a form of plaster splint which he believes fulfills every requirement. Gauze such as is used for making gauze bandages is employed. The splints consist of from eight to twelve folds of this gauze, between the layers of which dry plaster is well rubbed in. Before applying they are immersed in warm water, squeezed out, and then more dry plaster is rubbed into their inner surfaces. No plaster cream should be employed. If the plaster is well baked, splints made in this way set very quickly and firmly and are very durable. The method of applying the plaster splints is as follows: Supposing the case to be one of fracture of one or both bones of the leg in the lower third, the plaster splints need only be carried as high as the knee. A pattern of the posterior splint is obtained by laying the sound limb on a sheet of paper and cutting round it with scissors. The splint extends from the root of the toes, under the heel, and up the back of the leg to just below the knee. It should be wide enough to embrace about two-thirds of the circumference of the limb. A good width should be allowed at the ankle to accommodate the projection of the heel. The pattern must be turned over so as to reverse the sides in cutting out the splint for the fractured limb. From ten to twelve folds of ordinary gauze bandage material should be laid out in a length equal to, and rather wider than, the pattern and cut out to form the posterior splint. This should be laid on a considerably wider piece of gauze and the whole thickness stitched together down the middle line. Dry plaster should be rubbed in plentifully between the layers of the gauze. The extra width of the outside layer of gauze should be split into tails on either side of the splint and the tails rolled up so that they may not become "taffled." The posterior splint should then be rolled up from either end on rollers. Two pieces of broomstick answer the purpose. The anterior splint is simply a strip, three to four inches wide, long enough to reach from the root of the toes to the knee. From eight to ten folds of gauze suffice and the ends should be secured by stitching them together. Plaster is rubbed in as in the case of the posterior splint, and the splint is rolled up on a piece of broomstick. The leg should then be bandaged evenly with a single thickness of flannel, a pad of wool being placed on either side above the heel, this being a point on which the splint is likely to cause pressure. The knee should be bent to a right angle and the leg laid on a support. Both anterior and posterior splints on their rollers are then placed in warm water for a few minutes to moisten the plaster. The surgeon then makes traction from the heel and foot. Counter traction is obtained by passing a clove hitch round the upper part of the thigh and tying to the head of the bed. Flexing the knee to a right angle eliminates one of the chief obstacles to reduction of the fragments by relaxing the gastrocnemius muscle. If the foot is kept at right angles to the leg and the inner side of the great toe in a line with the internal malleolus and the inner side of the patella the fragments will come into correct position on making traction. The anterior splint is now unrolled and laid along the front of the leg and foot. The posterior splint is removed from the water and well squeezed out. It is then unrolled and laid under the limb. Some additional plaster may be rubbed into its upper surface. While the surgeon keeps up traction and maintains the foot in the correct position an assistant brings the posterior splint round the under surface of the leg and foot and fixes it in position by tying the tails over the anterior splint. It is better to avoid tying the knots directly over the sharp anterior margin of the shin, where they may cause undue pressure. Traction with the foot in the correct position must be kept up until the plaster is set sufficiently hard to prevent displacement of the fragments; three minutes generally suffice. The leg is left for about half an hour lying flexed on the box with a support, such as a thin book, under the heel and hot-water bottles or bricks on either side to hasten the drying of the plaster. After about twelve hours the plaster will be perfectly hard and the patient may then be allowed up on crutches. Unless there is any special reason for cutting up the case it is usually left untouched for about three weeks, when a fair amount of union may be expected to have taken place. It is then cut up with a pair of scissors along the interval between the two splints and subsequently the limb should be removed from the case about twice a week for passive movements of the ankle. After replacing it the splints should be bandaged firmly with a calico roller. If the fracture is above the lower third of the leg it will be necessary to fix the knee joint. The splints may be put on in the same way, except that the knee will have to be in the extended position and the splints carried as high as the middle of the thigh. The advantages claimed for this form of plaster cast are the following: 1. It is applicable to all cases of fracture of the leg, with the exception of certain cases of compound fracture. 2. Its method of application is simple. 3. It is rigid and durable. 4. It can readily be cut up without disturbing the limb, and can be reapplied without loss of rigidity. 5. It is put on with the limb in the most favorable position for reduction of the displacement—i. e., with the knee flexed and the gastrocnemius relaxed. 6. The position of the leg is not shifted and traction on the axis of the limb is kept up during the whole time of application of the splints. Consequently there is a fair certainty of the fragments being fixed in good position.

Semaine Médicale, Paris.

27 (XXV, No. 42, October 18.) *The Struggle Against Tuberculosis, According to the Labors of the Paris Congress.—La lutte contre la tuberculose. L. Cheinisse.
28 (No. 43.) Esophagoscopie et trachéobronchoscopie. J. Garel.

27. **Present Status of Campaign Against Tuberculosis.**—Cheinisse remarks that the first enthusiasm for the sanatorium as the sole means of salvation from tuberculosis has subsided. The recent international congress showed this declining tendency in a marked degree. The sanatorium for the well-to-do person, who can modify his mode of life afterward so as to maintain the benefit derived, is still the great benefit claimed at first. Members of the working classes, however, return from the public sanatorium to their old poverty-stricken environment. Their zeal and conviction will gradually be modified, and they will refrain from using their pocket cuspidore for fear of the prejudices of proprietors and fellow-workmen, as it stamps them as dangerous. The rôle of the sanatorium in prophylaxis is thus illusory; its therapeutic rôle, evidenced by the restoration of the working capacity, is more than dubious, as it is subordinate to the natural progress of the disease and to the occupation of the individual. On the other hand, the expense of the public sanatorium as conducted in Europe is out of all proportion to its purely palliative effect among the laboring classes. It should be reserved for the incipient cases, and should be regarded merely as the auxiliary to certain more general hygienic measures. Cheinisse cites Beco to the effect that the sanatorium has been too long regarded as the pivot of the antituberculosis campaign, when in reality it is only a secondary element. The German advocates of the sanatorium confessed that about 7 out of every 10 applicants have to be rejected. The tuberculosis dispensaries are more humanitarian than sociologic in their aims, and Calmette calculates that in the one at Lille it costs about $14,500 dollars a year to care for 100 families, exclusive of expenses of installation. Experience has also shown that, besides the true scientific and useful dispensaries, pseudo-dispensaries spring up for advertising purposes, which, under the guise of benevolence, are in reality but centers of competing interests to advertise the physician in charge and his assistants as specialists, and to advertise politicians connected with the inception and promotion of the dispensary. These various interests obscure the real work of the dispensary, and absorb the attention which should be devoted to the patients, so that the latter find themselves at the mercy of regrettable practices where seances of electrization or ozonation or exploitation of pharmaceutic specialties substitute hygienic regulations. The congress adopted a resolution to the effect that the sanatorium and the dispensary are neither exclusive nor predominant in the campaign against tuberculosis, but that the prob-

lem of healthy homes will always dominate its prophylaxis. Courtois-Suffit preached that the economic factor is the main one in the campaign against tuberculosis. "The conditions of life of the working classes must be changed. Their starvation wages must be raised by modifying the conditions actually existing between capital and labor." Cheinisse concludes with the remark that until this has been realized the economic conditions of the working classes will oppose an inflexible veto to the extermination of tuberculosis. "However," he adds, "the interests of the mutual benefit societies, the sickness insurance societies on the mutual plan and of similar organizations would be promoted by reducing the morbidity from tuberculosis, and they may prove a powerful aid in the campaign when they once awake to this fact." Another innovation which promises much is the organization of charitable societies whose aim is to remove healthy children from tuberculous environments and place them in healthy homes in the country or elsewhere. France takes the lead of all countries in its care of weakly children, sending those affected with tuberculosis to seaside health resorts and sanatoriums. It again leads the way in the recent organization of the Society for the Preservation of Children against Tuberculosis, which does not wait for the children to become tuberculous, but removes them from the infectious surroundings at once if it proves impossible to improve the home environment.

31. Removal of Foreign Bodies by Aid of Esophagoscopy.—Since 1887 von Hacker has been urging the necessity for direct inspection, preliminary to extraction, of a foreign body in the esophagus. He reported 27 cases in 1901 and now reports 12 more, in all of which extraction of the foreign body *proceeded smoothly* after its shape and location had been determined with the esophagoscope. He thinks that the surgeon should practice esophagoscopy as a routine procedure, just as cystoscopy has been adopted. In his experience, pieces of bones were found in 8 cases, false teeth in 4, and fruit stones in 2. In 17 cases in which there was a cancer or stricture, the foreign body proved to be a chunk of meat in 8, and a plum stone in 6, a cherry stone in 2 and a marble in 1. In 3 cases he was able to remove a plum stone with forceps from above, controlled by esophagoscopy. Local anesthesia with 20 per cent. cocain has always proved sufficient for adults, but for children he generally prefers chloroform anesthesia.

32. Sciatic Scoliosis.—Lorenz shows by several diagrams that sciatic scoliosis is the result of instinctive reflex contraction of the muscles: It protects the lumbo-sacral nerves against mechanical, painful traction, and no attempt should be made to correct this *scoliosis* while the affection is in its painful stage. On the contrary, the trunk should be immobilized in the position which the patient finds is least painful. Any other mode of fixation increases the painfulness and the cast has to be taken off.

33. Indications for Operative or Non-operative Treatment of Affections of Adnexa.—The statistics of Keitler and Peham show that in one-sixth of their cases of suppurative affections of the adnexa treated by conservative measures the patients regained complete functional capacity, as evidenced by pregnancy later. This surpasses the results attained by operative measures. When operating in cases of pyosalpinx, von Franqué now makes a practice of suturing the wall of the abscess to the wall of the vagina, as also in cases of suppurating hematocele. This insures constant drainage; an ordinary drain is liable to become displaced or to be removed by the patient, as occurred in some instances which he cites. As a rule, in gonorrheal or puerperal pyosalpinx the patients have more or less temperature, but it is reduced to normal in one or more weeks by mere rest in bed and application of the ice bag. The spontaneous and induced painfulness of the tumor in the adnexa subsides more slowly, while the tumor gradually shrinks in size. Several days to a week after the temperature has been reduced to normal, he commences hot irrigations of the vagina, followed by ichthyol-glycerin tamponing. This is supplemented by alcohol compresses or Priessnitz packs to the abdomen. Superheated air can also be applied locally to good effect in so far as the pains are concerned, although his experience has not shown any decided superiority of the superheated air in gynecology over other methods of treatment. His patients were kept reclining until the tumors had grown smaller and were no longer painful, which occurred on an average in from four to six weeks. Then baths were given, especially Franzensbad brine baths, and this course of brine baths was repeated a year afterward. Patients able to be treated according to this plan seldom require operative measures for a gonorrheal or puerperal pyosalpinx. The brine baths must not be commenced until after the temperature has been normal for from six to eight weeks, and they should be suspended at the least rise. He warns, further, against massage. It can not do much good, he says, and is liable to do great harm, mobilizing the germs and spreading them into hitherto sound regions, while cautious tamponing, rinsing and baths leave them undisturbed and enclosed in the more or less quiescent focus. Operative intervention is indicated on suspicion of cancer and when symptoms indicate torsion; also when the symptoms suggest that a tuberculous process in the adnexa is the primary or principal localization of the affection. Von Franqué has had 11 out of 13 patients who have been in good health for from eleven months to ten years after a radical operation for tuberculosis of the adnexa. In other patients, he was able artificially to wall off the focus from the abdominal cavity, even when there was already a communication into the rectum. Infection from the field of operation occurred in only 1 out of the 20 tuberculous patients on whom he has operated, and possibly it might have been prevented by more ample drainage in this instance. A simple hydrosalpinx can be evacuated if it causes trouble.

36. Surgical Treatment of Otogenic Meningitis.—Alexander describes the technic at Politzer's clinic. It consists in immediate operation on the ear and removal of the entire disease focus, then exposure of the dura, incision and drainage of the intradural space, suction and aspiration of the fluid through the opening thus made, and lumbar puncture. The virulence of the micro-organisms is an important factor in the results of treatment, and this should be determined at once, preferably by inoculation of animals. This was scarcely attempted in the 10 cases treated by operative intervention on record. Five were essentially improved. The indications for operation require the differentiation of suppurative from serous meningitis, and for this reason lumbar puncture is imperative. Repeated lumbar puncture for therapeutic purposes may be advisable in meningitic affections not originating in the ear, or when the focus is not accessible, but in otogenic meningitis local surgical intervention and local aspiration of fluid from the intracranial regions lying near the ear are preferable. In case of suppurative meningitis, the dura should be opened wider, with an incision from 1.5 to 5 cm. long. Counteropenings may be useful to promote ample drainage. Politzer made a counteropening in the posterior cranial fossa, behind the sinus, in 2 cases with good results. In cases of far advanced otogenic suppurative meningitis, it might be advisable to expose the brain and to remove the outer diseased layer in case of existing encephalitis. Manasse has recently recorded a case of serous meningitis with superficial encephalitis, which suggests the possibility of removing the softened diseased membranes and the adjacent layers of the cortex in such cases, as also in the early stage of the suppurative form. Experience has fully demonstrated that exploratory opening of the cranial fossa in connection with the operation on the ear is a less dangerous procedure than temporization.

37. **Causal Treatment of Cutaneous Affections.**—Kreibich believes that a certain number of cutaneous affections are sympathetic reflex phenomena. The stimulus is not exerted on the vasomotors directly, but indirectly, by sensory stimuli, centrally transmitted. The pathologic intensity of the effect is due either to the intensive sensory irritation, as, for instance, in the affection of the ganglion in herpes zoster, or else to the abnormally increased excitability of the vasomotors. This pathologic excitability which causes the vasomotors to react to sensory stimuli with a pathologic response can best be explained by assuming a lack of stability on the part of the dominating vasomotor center. He is convinced that this is the cause of gangrene of the skin, of urticaria, prurigo, glossy skin, decubitus, etc., while Raynaud's disease is due to abnormal excitability of the vasoconstricting instead of the vasodilating center. Local measures are unable to influence such a vasomotor phenomenon. It must be attacked at the source, by preventing the afferent sensory irritation and by reducing the central reflex excitability. For the latter, the most effectual weapon at our command is arsenic. It acts on the central nervous system, as is shown by its efficacy in chorea, and by the fact that too large doses induce typical reflex phenomena, such as arsenic zoster and urticarial, painful erythema. When an affection with itching follows certain lines or appears in symmetrical regions, its origin in the central, sensory tracts becomes apparent, and arsenic is the remedy *par excellence* for the condition. He relates experiences which demonstrate beyond question that this drug is superior to other remedies in reducing morbidly exaggerated reflex excitability. It has proved exceptionally successful in all long-persisting, urticarial, urticaria-erythematous or purely pruriginous conditions. Inadequate or unsystematic dosage is generally responsible for the failures. He gives it in the form of Fowler's solution and aqua menthæ, equal parts of each. Five drops are taken morning and evening, then ten drops morning and evening. He keeps the patient on this dose until its effect is apparent. If stomach symptoms develop, he continues the arsenic in the form of subcutaneous injections of sodium arsenate. When convenient, he combines the subcutaneous injections of .02 gm. of the sodium arsenate every second day with five drops of the above mixture morning and evening.

40. **Spirochetes in Syphilis.**—Sobernheim remarks that the findings of spirochetes coincide with the clinical experience in regard *to the transmission of syphilis. He found them in 50* out of 58 cases of certain syphilis, all the positive cases being those with primary or secondary lesions, while the 8 negative cases were those with tertiary lesions. In 34 control cases of various affections, the findings were invariably negative. Herxheimer states that perfected staining technic has resulted in the discovery of certain bodies in or near the spirochetes which he regards as confirming their protozoan nature.

42. **Changes in Granulation Tissue After Treatment by Suction Congestive Hyperemia.**—Hofmann gives illustrations of the microscopic changes in the tissue after it had been treated with Bier's suction apparatus to induce congestive hyperemia. He was surprised to find that the leucocytes had nearly vanished *from the region, actually washed away* by the congestion and hyperemia induced. The benefit of the procedure must lie in the fact that the bacteria and their poisons are washed away also, while the influx of fresh blood to the parts brings renewed life and vigor. The histologic picture shows that the vessels become much enlarged under the suction, while the composition of the blood is comparatively normal, showing no preponderance of leucocytes. The parts have merely been thoroughly rinsed and drained.

44. **Signs of Typhoid Fever.**—Treupel has been diligently sifting the clinical records of 60 cases of typhoid fever recently observed. The anamnesis suggested the possibility of typhoid in only 75 per cent.; a typical temperature curve was noted in only 46 per cent.; bronchitis at the commencement of the disease in 48 per cent.; pulse slow in proportion to the temperature in 86 per cent.; tendency to euphoria or remarkably good general condition in 56 per cent.; typhoid tongue in only 16 per cent.; catarrhal sore throat in 33 out of the 60, and follicular sore throat in 1; abdominal symptoms, meteorism, tenderness, etc., in 61 per cent.; enlarged spleen in 86 per cent.; roseola in 71 per cent.; diazo reaction in 73 per cent., and the agglutination test positive in 90.6 per cent. of 53 patients, and typhoid bacilli found in the blood by the second or third day in 92.8 per cent. of 14 cases. In 3 cases, the *clinical picture was at first that of a rhinolaryngeal bronchitis*, without roseola, enlarged spleen or diazo reaction, but the positive findings of the agglutination test were confirmed by the course of the disease. In another case, a woman recovering from childbirth had chills. The uterus was normal for her condition and the persisting euphoria suggested the possibility of typhoid, which was sustained by the positive agglutination. In another case, a woman presented considerable cachexia, dullness over the apices, hectic fever and strongly positive diazo reaction. The lung affection seemed to remain stationary and no bacilli could be found in the sputa, while the diazo reaction grew more and more marked, and the fundus of the eye showed no signs indicating miliary tuberculosis. The agglutination test was very strongly positive, and typhoid bacilli were finally cultivated from a furuncle *on the leg and from the urine.* See editorial page 1575.

45. **Serum Treatment of Fibrinous Pneumonia.**—Lindenstein's experience in 4 cases has been extremely favorable.

47. **Suction Hyperemia in Treatment of Tendon Sheath Phlegmons.**—Lossen gives illustrations of the remarkable functional results attained in 3 cases of tendon-sheath phlegmons in the hand, treated by Bier's method of congestive hyperemia. Healing was prompt and the tendons did not become contracted *or necrotic, but resumed normal functioning.*

48. **Fatal Complication of Exploratory Excision.**—A woman of 40 presented atypical uterine hemorrhages and, although in apparently the best of health, the suspicion of cancer was excited by the aspect of the portio vaginalis, and an exploratory excision was made. Symptoms of septicemia developed at once and the patient died in less than a month. She had been referred to a careful surgeon for the excision, it had been done in a well-equipped operating room, and the field had not been touched by the hands nor was any other sin against asepsis committed. The exploratory excision had revealed incipient carcinoma and also several mucous follicles which had become closed at the mouth and distended by their secretion. Steinbüchel had seen such little cysts before and had had occasion to open some of them with the thermocautery on several *occasions in years past.* It was noticed during the exploratory excision that the contents of two of these Nabothian follicles had a somewhat different appearance from the others, as if pus were mixed with the mucus. *At the same time, a small vein had* been opened by the exploratory excision. The vein was sutured and the lips of the wedge-shaped excision brought together and sutured. Two sutures for a wound only *about an inch long did not* close it hermetically, but he ascribes to these sutures the evil results. If the wound had been left open and drained, the germs would have been drawn outward.

They must have been exceptionally virulent, and some must have found their way into the opened vein and thus have transformed a clean wound into an infected one. He advises, therefore, in case a retention cyst of this kind is opened in the course of an exploratory excision that it should not be sutured, but should be merely tamponed and drained. In any event, a patient should be carefully supervised after an exploratory excision.

49. **Eye Affections and Autointoxication.**—Groyer announces that the test for indican resulted strongly positive in a large number of cases of eye affections for which he could not discover any primary cause. They included cases of scleritis, keratitis, iritis, iridocyclitis, retinitis, choroiditis, neuritis, retrobulbar neuritis, cataract, opacity of the vitreous body, hemorrhages in the vitreous body, glaucoma, atrophy of the optic nerve, hemianopsia, scotoma, paralysis of the ocular muscles and functional disturbances for which no cause could be discovered. In all of these cases, he noted evidences of digestive disturbances with tenderness on pressure of the regions of the stomach, liver, gall bladder and spleen, or typical pains in the sacral region and between the shoulder blades, radiating into the shoulders and arms; or else pain on pressure of the emerging points of the lateral branches of the intercostal nerves, the cervical plexus, the supraorbital, infraorbital and mental nerves, or radiating pains in the forehead and temples and occiput, or pronounced palpitations or nervous respiratory disturbances. In all the above ocular disturbances no affection of any other organ could be detected. In all these cases, the tests for sugar and albumin in the urine always resulted negatively, while the tests for indican revealed its presence in very large amounts. As indican is an indication of putrefactive processes going on in the intestines, he assumes that its presence in these cases indicates that poisons from the intestines are circulating in the body of these patients, these intestinal toxins affecting primarily now this, now that organ of the body. Their ravages are most readily perceived in the eye, and hence the ocular disturbances were the first to attract attention.

54. **Abdominal Extirpation of Uterine Cancer.**—Latzko makes it his principle in operating on a cancer of the uterus to remove all the glands, lymphatics and vessels, with the connective and fat tissue, *in toto*. He gives an illustration of the piece removed, a long chain of glands hanging from it on each side, and describes his technic in detail. The only possible dubious feature in regard to asepsis is the cutting of the uterus out of the vagina, but this is the last step in the operation. Ten patients operated on by this technic all recovered with remarkably little suppuration. He ascribes this to the ample drainage, the lack of recesses in the connective tissue, and the avoidance of mass ligatures. This technic, he claims, demonstrates the feasibility of removing all the suspicious elements in extirpating a cancer without enhancing the gravity of the operation.

58. **Etiology of Pterygium and Pinguecula.**—Sachsalber reiterates his previous announcement in regard to pterygium and pinguecula as being the result of irritation from the presence of fine downy hairs on the inner side of the lids. He does not claim that all cases are of this origin, but that a large proportion can be traced to this source and that a cure can be effected by removal of the hairs. The hairs are generally found in the inner angle; in some cases he has found them so long that they projected 2 mm. beyond the limbus of the cornea, but they are so fine that they can seldom be seen without a magnifying glass. He describes a series of 6 cases, and states that in examination of 1,100 inmates of an insane asylum he found the hairs in all but 3 of the individuals affected with pinguecula, and in nearly all the cases of progressive pterygium. The stationary, traumatic cases, of course, do not belong to this category. His first article was summarized on page 1971 of the last volume of The Journal.

59-60. **Experiments with Inhalation of Drugs and Germs.**—Bartel describes an apparatus which supplies a very fine spray blended with compressed air for inhalation. Hartl and Herrmann report experiments with the apparatus on animals compelled to inhale a spray containing the *Bacillus prodigiosus.* It was found that the bacilli inhaled were caught on the walls of the nose and throat, while but a very small number of them reached the peripheral portions of the lungs. The experiments proved, however, that the inhaled spray from the apparatus actually found its way to the remoter parts of the air passages. The inhaled bacilli did not proliferate.

61. **Seven Cases of Pancreas Cysts.**—Exner has been collecting information in regard to the later fate of 7 patients with cysts in the pancreas who were operated on at Hochenegg's clinic. The cases have all been previously published. One of the patients was treated by total extirpation of the cyst and is in perfect health. Of the other 6 patients only 2 are still alive after ten years, and one of them has a recurring fistula. These 6 patients had been treated by suturing in the cyst. Death was due in one instance to ileus from adhesions. In a more recent case a man was kicked in the stomach region by a horse. When seen six weeks later, he had a tumor in the pancreas region, with sugar in the urine, a sign of functional disturbance in the pancreas. The tumor increased in size during the day, but the next morning it suddenly subsided, having perforated into the abdominal cavity. This did not cause any special disturbances. The tumor was probably a hematoma in the pancreas, and its rupture put an end to the functional disturbances in this organ. Four months later the tumor had recurred. This time it proved to be a cyst, and no traces of the preceding hematoma could be discovered at the operation. The cyst was drawn up and sutured to the parietal peritoneum, and not opened until five days later. Its wall was about 3 cm. thick. A small drain was inserted and the secretion gradually subsided from a quart in the first twenty-four hours to 300 c.c. in about five weeks, and then became minimal. The fistula has not healed during the five months since, and it is now proposed to remove the shrunken wall of the cyst to facilitate closure of the fistula.

62. **Portable Blood Pressure Measure.**—The little instrument consists of a manometer with a tube on each side of its base. One tube connects with a broad ring slipped over the finger, the other with a small syringe which serves to compress the air in the tubes.

66. Influence of Cold and Heat on Certain Affections.—Leonardi, in central Italy, has been studying the records of 107 cases of cerebral hemorrhage during the last fourteen years. He found that 71 cases occurred during the three coldest months and 23 during the three hottest months, while only 15 were observed in fall and spring. This fact, in connection with others which he cites, he thinks, demonstrates that the visceral congestion during cold weather is responsible for the hemorrhages. The blood is driven away *from the periphery;* it accumulates in the right heart, with consequent enlargement of the vessels and tendency to rupture. During the summer the blood is drawn to the periphery, and the heart is *overtaxed. The brain is a peripheral organ, and consequently* the congestion in its vessels is liable to entail rupture. The extremes of the seasons thus have the same effect, but by a different mechanism. The gastrointestinal tract also suffers in the same way, the visceral congestion in winter and the anemic condition of the viscera during the summer causing disturbances. The result of each is *identical,* that is, abnormal digestive functioning, and the presence of imperfectly digested food in the alimentary tract, entailing autointoxication and consequent nervous depression.

68. Pathogenesis of Hydrocele.—Cecca has demonstrated that certain portions of the parietal peritoneum are semipermeable, that is, they allow the passage of water alone while holding back its salts. He believes that when the vaginalis has developed from the part of the parietal peritoneum exhibiting this property, a predisposition is afforded for the development of hydrocele. He describes his experiments on animals and on the cadaver and tests of the membrane taken from normal individuals. All concur in demonstrating only semi-permeability on the part of the membrane in the cases of hydrocele.

69. New Method of Serodiagnosis of Typhoid.—Appiani writes from Lucatello's laboratory at Padua to describe a technic for the serodiagnosis of typhoid by means of the precipitating action of the pulp of typhoid bacilli. He thinks that the procedure described is more reliable, more practical and simpler than the ordinary agglutination test. He first made a large amount of bouillon culture of pure and extremely virulent typhoid bacilli. On the eighth day he filtered 2 liters of the culture through a Chamberland filter, rinsing by passing sterilized and distilled water through the filter for twelve hours. The pellicle left on the filter was ground for four hours in a mortar, a few drops of distilled water being added occasionally. The result was about 20 c.c. of a turbid, milky colored fluid. This was filtered again, and the result was a clear fluid, slightly alkaline, not coagulating with heat nor throwing down a precipitate with the ordinary reagents for the albuminoids, and becoming only slightly turbid when treated with acetic acid and potassium ferrocyanate. A few cubic centimeters of serum from a typhoid patent were placed in test tubes arranged in a stand and 5 c.c. of the bacillus pulp, obtained as described above, was allowed to flow down the wall of the tube on top of the serum. No change was observed in the contents of the test tube for nearly two hours. Then the fluid began to grow turbid, until it was entirely turbid after the third hour. A clear zone then developed at the point of contact, becoming most pronounced by the seventh hour, the fluid above and below remaining turbid indefinitely. These results were observed in serum from a patient at the twelfth day of typhoid. In another at the twenty-first day, the process proceeded much more rapidly, the whole being complete in an hour and a half. Appiani is now experimenting with *the colon bacillus* by the same technic.

70. Freezing Point of Urine in Infectious Diseases.—Mariotti reviews the history and present status of cryoscopy, and adds that most of the communications on the subject have been devoted to the conditions in heart and kidney affections. In this article he gives tables with the details in regard to the urine in 8 cases of typhoid, pneumonia, malaria or tubercular meningitis. These tables demonstrate that the molecular diuresis is low in febrile infections, but it may become abnormally high during convalescence. This is probably due to the elimination of the substances retained during the course of the disease. Cryoscopy of the urine in acute infectious diseases is a better indication of the condition of the organic metabolism than of the functional capacity of the kidneys.

71. Prophylaxis of Malaria.—Casardi mentions that the present season has been an unusually wet one, and yet the prophylactic measures introduced against malaria have succeeded in keeping down the morbidity from this cause. The proportion of persons primarily affected has dropped from 38.71 per cent. to 0.3 per cent. since the houses have been screened, in one of the greatest hotbeds of malaria. In the regions where malaria is not bad, prophylactic doses of quinin are sufficient to ward off infection, but in the worst infected districts mechanical measures are indispensable. He adds that the term malaria means bad air, but that the air has been exonerated of complicity in the development of malaria except as it bears up the wings of the mosquitoes. He concludes by urging legislation to compel the screening of all houses in malarial districts.

76. Relations Between Pericarditis and Valvular Lesions of the Aorta.—Ferrio reports five cases of valvular affections superposed on pericarditis and discusses the connection between them.

77. New Danger of Omentopexy.—A robust man of 32 exhibited symptoms of cirrhosis of the liver and, as the ascites was large and annoying, omentopexy was undertaken to provide collateral circulation for the portal vein. The operation proceeded smoothly and the patient was convalescing satisfactorily when, on the third day, symptoms of collapse became apparent and he died in a few hours. The autopsy revealed laceration of one of the veins in the omentum. This accident was explained by Maragliano as the result of an effort to vomit. The stomach in the retching must have pulled on the omentum and torn one of the vessels, with resulting *hemorrhage. The attendant did not realize the seriousness of* the symptoms until too late. If the surgeon had been called at the first sign of collapse the laparotomy wound might have been opened and the ruptured vessel sutured. The case is a warning to make the fixation high up and to pull the omentum down as little as possible. Everything should be done to prevent vomiting until solid adhesions have formed; a week is long enough for this, as a rule.

78. Remedy for Defective Secretion of Milk.—Burzagli reviews the history of attempts, ancient and modern, to increase the mammary secretion, and relates the fine results he has obtained with anise. He learned that veterinarians were using anise as a reliable galactagog, and when he was consulted by two women who deplored the lack of sufficient milk for their infants, he recommended them to drink an infusion of aniseseed and to apply to the breasts four or five times a day compresses impregnated with the infusion. After five days both women were able to supply all the milk the infants needed. Each had used about seven quarts of the 25 per 1,000 infusion, taking five quarts internally. It was continued for another five days and then suspended, but the secretion of milk remained abundant. The effect is not apparent till from the *third to the fifth day.*

THE SECRET NOSTRUM EVIL.

FRANK BILLINGS, M.D.
CHICAGO.

I shall make no apology for bringing this subject before this Section. Its importance to the profession of medicine and to the public justifies an exposition of the evil now. In no other country has this menace to the welfare of the people and to the best interests of scientific medicine developed as it has with us.

Probably the reason is that other countries, with one or two exceptions, protect the people against frauds in foods, medicines, etc.

Some day it is to be hoped that the Congress of the United States will enact a national pure food law which shall include the regulation of the copyrighting and exploitation of proprietary and other medicines.

Just here it will be well to say that the term "proprietary medicine" does not necessarily stamp a preparation or remedy as a nostrum. Webster says that a nostrum is "a medicine, the ingredients of which are kept secret for the purpose of restricting the profits of sale to the inventor or proprietor; a quack medicine." Some proprietary medicines are patented, or better, the process of manufacturing an article is patented. This patent protects the discoverer, or owner, in the manufacture of the medicine or drug for a period of 17 years. These preparations are ethical, in that they are not secret, for any one for a small fee may obtain from the patent office of the government a copy of the description of the process of manufacture and the actual chemical composition of any such patented drug or remedy. The chief harm which has come to us in America from the protection by patent of the process of making a chemical or drug has been the resulting high price of the product. Many of the synthetic chemical drugs, like antipyrin, phenacetin, etc., cost ten times their worth as compared with the price of the same drugs in Germany and in other countries. As stated, however, such really patented preparations are not secret; the composition is known. Some of them are of value therapeutically. Many of them are valueless. Some of them are harmful. Most of them we could easily get on without and fare better with the older, more simple remedies. Too many "made in Germany" specifics are shoved under our noses.

Now, as to the other proprietary medicines. All the so-called "patent medicines" put on the market for the public, and many of the preparations exploited to physicians and distributed by them to the public, are not patented, but are protected by a copyright or trade mark. Technically there is no difference between the secret proprietary medicines manufactured for physicians' use and the "patent medicines" exploited to the public. Both are protected by a copyright or trade mark name. Both are protected for an indefinite time. They are mixtures, as a rule, of several ingredients.

The relation of the physician to these preparations, however, is very different. Those "patent medicines" which are advertised to the public are not considered ethical and physicians abhor them and rightly condemn their use because they are often dangerous and always irrational as remedies. On the other hand, the manufacturers of those copyrighted proprietary medicines which are exploited to physicians by extravagant claims of specific therapeutic action, use the doctor as the middle man to distribute the cure-alls to the public.

Medicines so prepared that the busy physician could easily dispense them found a certain class of doctors eager to use them. The indications for use appeared on the label or in the accompanying literature. Tonics, blood and tissue builders, emmenagogues, pain relievers, febrifuges, laxatives, calculi dissolvers, soporifics, bile promotors, heart tonics, cures for Bright's disease, etc., have appeared in countless number and some remedies offered are confidently presented as cures for not one, but a half dozen diseases or symptoms complex. Indeed, the claims of many of the promotors of this class of remedies do not differ in extravagance from the cure-all patent medicines offered directly to the public.

It has been easy to obtain testimonials of the alleged value of many of these remedies. Many even of the "faculty" have extolled them. Why, therefore, should not the less experienced physician use these "elegant," palatable, all-ready to use, with label-specifying-dose, disease-indicating remedies? Prominent physicians and the "faculty" had testimonials in the circulars sent with the samples indicating the virtues; why, therefore, use the simple proved remedies of the pharmacopeia, and especially as the latter would often necessitate the trouble of writing a real prescription.

To the rational physician most of the mixtures, even with the formulæ, are objectionable. Disease is never quite the same in different individuals, nor does the picture remain the same from day to day. The treatment must be modified to meet the varying problem of the morbid process. Rational therapy calls for simple prescriptions; but if there be an objection to mixtures with fixed and known formulæ, what must one say of mixtures of secret or semi-secret composition?

As Dr. Horatio C. Wood, Jr.[1] says:

> A much more elusive and therefore dangerous evil lurks in the class of mixtures which attempt to cloak their secrecy with a deceptive show of frankness. I think you will grant that the physician is rarely justified in the use of remedies concerning which he has no knowledge, and I maintain that the publication by a drug firm, of whose integrity the physician is absolutely ignorant, of a professed list of ingredients of some mixture is not sufficient knowledge to pardon

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] "Proprietary Therapeutics," The Journal A. M. A., June 10, 1905, p. 1836.

or to warrant the uses of that remedy. In the first place, if the published formula be correct, it is not enough to know simply the composition of a mixture, the exact quantities must also be known; there is a vast difference between the effects of 1 grain and of 100 grains of opium. Moreover, there is no means of knowing that the formula is a true one, for many of these corporations do not hesitate to pervert the truth.

Many of the promotors of these preparations claim, as chemists or as pharmacists, to be the discoverers of the wonderful remedies and the alleged unusual knowledge of chemistry or of skill in pharmacy has enabled the discoverer to develop in a mixture heretofore unknown, therapeutic qualities. Truth to tell, however, it is known that the proprietors are not always the manufacturers of the preparations they exploit and distribute. Many of the proprietary preparations are made by the large manufacturing pharmacists for the owners. Pharmaceutic skill is doubtless used in these instances, but it is the kind of skill which is for sale and is not personal.

I am informed that it is not unusual for one manufacturer of proprietary mixtures to have several so-called "companies," through which he can more easily exploit and distribute his products.

There is said to be a direct relation between the Dad Chemical Co., the Od Chemical Co., the Sultan Drug Co., the Rio Chemical Co., and the Peacock Chemical Co., or at least that they are linked together through one individual, and that Battle & Co. and the Lambert Pharmacal Co. are related to the above list. It is said, too, that the Vass Chemical Co., the Lotos Chemical Co., and the Valley Chemical Co. are one combination. Doubtless other combinations exist.

Curiosity recently prompted me to look through a number of medical journals and I can not resist the temptation to quote some of the preparations advertised in them: Aletris Cordial, Celerina, Neurilla, Respiton, Sanmetto, Cactina Pillets, Seng, Chionia, Thialion, Zarcol, Ecthol, Hagee's Cordial of Cod Liver Oil Compound, Mandragorine Tablets, Rheumagon, Ponca Compound, Ammo-phenin, Chloro-Bromon, Anasarcin, Bronchiline, Zematol, Zymoticine, Sulphogen, Labordine, Satyria, Manola, Cacodol, Eusoma, Leprosen, Sulpho-Naphtol, Pas-Avena, Neurosine, Germiletum, Bonn's Passiflora Tablets, Dioviburnia, Tongaline, Lithiated Hydrangea, Melachol, Gonoseptone, Calicolo, Saliodin, and so on *ad infinitum*. These are only a few samples of what the physicians of the United States are asked to prescribe. But there are hundreds of secret preparations that are not advertised in medical journals, whose literature and samples come to us through the mails, etc. In the majority of cases, we do not know their contents, and in many instances an analysis shows that they are simply mixtures. Often a prescription written by a physician for a particular case is purloined, put up under a trade-name and exploited as a cure-all.

As an illustration see the official announcement of the Council on Pharmacy and Chemistry regarding certain nostrums that have been exploited as synthetic chemical preparations guaranteed to cure everything. I have no doubt that the majority of the physicians who have been prescribing phenalgin, antikamnia, sal-codeia (Bell), and ammonol were shocked when they found out that, according to the analyses, they had been giving a simple mixture of acetanilid, with bicarbonate or salicylate of sodium or carbonate of ammonium, with a little caffein in some instances. What physician will be foolish enough to use these preparations, when he can get the same of his druggist for at most one-tenth the cost, but especially what physician with a particle of medical knowledge would think of giving acetanilid if he knew it, in the majority of the conditions in which, according to the advertisers, these nostrums are indicated?

What physician would prescribe Gray's glycerin tonic, if he knew that its chief ingredients are gentian, dandelion, glycerin and sherry wine?[2] Could he not write a prescription as good and feel that he was his own judge of what constitutes a tonic?

Let me quote from The Journal A. M. A.[3] This, I am told, refers to an article advertised as a cod liver oil preparation—one of the tasteless kind, that has been investigated by a subcommittee of the Council:

> We have recently had occasion to open a package of a well-known "Tasteless Cod Liver Oil" preparation. The circular which was wrapped about the bottle was replete with interesting information, especially for the patient, who obtains the remedy in the original package, as prescribed by his physician. He finds in it a list of the diseases in which the preparation does wonders—they range from the dread consumption to cystitis and hemorrhage of the kidney. Most interesting to us, however, is the statement that this compound "contains all the necessary elements of nutrition." It is too bad to disturb this beautiful vision by the report of the chemist. This shows that the product is quite free from oil or proteids; the only nutrient ingredients are alcohol, sugar, and perhaps glycerin. But the claims of the manufacturers are probably correct, for it contains carbon, hydrogen, oxygen, and probably a trace of nitrogen—so does gunpowder.
>
> Perhaps it will now be the turn of strychnin to be advertised as the ideal food. It seems superfluous to point out the moral of this tale.

It is not necessary to enter into a discussion as to whether we should ever prescribe secret proprietary medicines, for in the minds of intelligent men, even with only a smattering of medical knowledge, there can be but one answer. A physician who has a true appreciation of his responsibilities, who has even ordinary knowledge of the action of drugs, and the danger from their unintelligent use, would not think of prescribing for the sick, who have placed themselves under his care, a preparation about which he knows nothing except what the manufacturer, about whom he knows less, had told him. While there is no excuse for prescribing these medicines, too many unthinking physicians are influenced to do so by the claptrap designated "literature," which the exploiters publish about their preparations.

There is not a secret proprietary preparation that has any more value, from a pharmaceutical or therapeutic standpoint, than has the ordinary prescription of the average general practitioner. Stop advertising them and they would be forgotten, just as "patent medicines" pass away if they are not advertised. A review of 10 or 15 years will call to mind many concoctions which physicians were asked to prescribe, and which, according to the advertisements, performed wonders, but now are heard of no more. Their advertising literature stopped coming and the nostrum-prescribing doctor ceased to use them.

What is the cause of the nostrum evil? There are several.

1. Pharmacology and therapeutics are neglected relatively by many of our medical schools. Anatomy, phy-

---

[2] "Each half ounce is stated to contain dilute phosphoric acid, 12 minims; gentian root, 10 grains; extract of taraxacum, 15 grains; glycerin, 80 minims; sherry wine, 80 minims; carminatives, q. s."—"Thesaurus of Proprietary Remedies," p. 148.

[3] June 17, 1905, p. 1943.

siology, pathology, diagnosis, etc., are emphasized and too often the usefulness and limitations of drugs are neglected. Too frequently drug nihilism is taught. If the student were fully taught the physiologic action of drugs, the art of prescribing, preferably single remedies or in simple combination, using if he desires the pharmacopeial preparations prepared by reliable manufacturing pharmacists, and at the same time if he were taught when not to rely on drugs, but frankly to prescribe for his patient a course of hygienic measures which alone would accomplish all that would be required, he would not be the willing dupe of the nostrum vendor, as he now is.

2. The reputable manufacturing pharmacists deserve great credit for the improvement they have made in pharmaceutical products. They have afforded us official preparations in the form of pills, tablets, syrups, tinctures, extracts, etc., which are elegant in appearance, often palatable and usually potent.

For this advance in pharmacy, a distinct credit to our country, we owe them our thanks.

Unfortunately, many of them have not stopped at this point, but have manufactured their own special mixtures which are just as objectionable as the products of the special manufacturers. They, too, have been active with their agents in visiting physicians and in distributing "literature." This encourages drug-giving in specific mixtures for special symptoms, and is wrong. With one hand they do good work, with the other much evil is done.

3. The nostrum makers at first copied the methods of the reliable manufacturing chemists, in exploiting their products, but they have gone a step further and have reached a point where one may say that they have subsidized the medical press. I know I am on dangerous ground when I make this statement, but right here is the chief cause—and the remedy. How many of our so-called medical journals are subsidized by medicine manufacturers I do not know, but all physicians know as well as I that there are many, and I do not refer to the so-called house organs. I unhesitatingly affirm that one-half of the medical journals of the country would be out of existence if it were not for the nostrum advertisements. Under the circumstances, therefore, can we expect these journals to say anything? Need we be surprised that scarcely a journal published the official report regarding the acetanilid mixtures, when the preparations hit were the best paying advertisements in the country?

What is the remedy? Publicity. The enlightenment of the profession. The truth regarding not only what the preparations contain, but who makes them. Certainly no honest manufacturer will object to this last proposition, and no honest physician will put up with less than the former.

The Council on Pharmacy and Chemistry has been created to investigate the non-official preparations, to find out the truth about them, and to publish its findings. It is not necessary to repeat here the results of the work already done by this body. All physicians have read, or may read all about it. In my opinion there has been no movement undertaken by the American Medical Association that will be so far reaching as this one to rid us of the blight of the nostrum evil. For the first time, we see the possibility of the elimination of a part, at least, of this curse to American medicine. It is the first practical solution offered of a most difficult problem.

But—and I want to emphasize what I am about to say—the movement will have the most determined opposition that money can bring. Millions are being made annually by the nostrum manufacturers, and they will not sit idly by and see this wealth-producing business done away with if they can prevent it. It won't be an open fight, for their business will not stand publicity. They will have with them those so-called medical journals which are published solely in their interests.

This movement will have the sympathy of every thinking physician of the country, but sympathy does not win battles. In this fight those who are representing us should have all the support we can give. In society meetings especially we should aid in the propaganda by helping to enlighten and to interest those of our profession who have given the matter no thought. We should support those journals that represent us, and not tolerate in our offices those that we know to be subsidized and to represent their advertisers rather than their readers.

DISCUSSION.

Dr. John H. Musser, Philadelphia, said that the cordial reception of this paper indicated that the members of the Section are in full accord with the sentiments expressed by Dr. Billings. He said that the nostrum evil as defined by Dr. Billings stultifies the profession in many ways. First it robs the physician of that practice of nice discernment in the choice of remedies, of their indications and their doses, which is essential to the full development of therapeutic skill. A physician's chief asset is experience, but what experience of the value of a remedy can be acquired when it is used in the manner in which we are instructed to administer it by the audacious five-dollar-a-day peripatetic therapeutist? Second, it prevents a cultivation of the scientific therapeutic habit, for, if premises are wrong, how can conclusions be correct? The uncertain combinations in unknown proportions, of unreliable remedies, concocted by unscrupulous grafters, can not possibly form a true figure in a proposition. Consequently, no true conclusions are drawn, and, hence, scientific habits are very soon cast to the winds. Third, it engenders irresolution as to the value of remedies. They are given in a half-hearted manner, and consequently a minimum effect is produced. A physician who prescribes with a clear knowledge of the effect of a remedy gets a surer and more immediate response. Doubt causes inaction. Fourth, it destroys scientific habits. If a scientific habit is not employed in our work, we are not truthful in our action. This lack of the worship of truth in treatment soon engenders a want of exactness in diagnosis. In consequence, a slovenly habit of practice in general will follow. Fifth, the doubt of the value of drugs and of medical measures is soon transmitted to the laity. Is it any wonder, Dr. Musser asked, that all *isms* flourish when physicians can not support their own therapeutic actions by experience or by scientific induction? The fact that every three years, perhaps less, the whole type of nostrums changes shows that experience has not been garnered. Time alone enables physicians to gather knowledge which the nimble "nostrum-mer" or drug drummer would prefer us not to have. Sixth, the nostrum evil threatens the enlightened principles of modern medicine. Our great glory is in adhering to the line of conduct of the tenets of Hippocrates and of Sydenham. "Do good or do not harm." It is not the use of drugs, but it is management and measures that mark our later-day progress. By the nostrum tenets, polypharmacy is essential and excessive drugging is the rule, both contrary to modern medical practice. Seventh, the nostrum evil stultifies physicians, because it makes them dishonest. They can not be honest if they prescribe things of which they know little or nothing. Dr. Musser urged medical men to be true to themselves and to hearken to the warnings of the paper. Concluding, he said: "Let us lash with thongs of indignation those tempters who, with literature that is beyond all measure untruthful, unscientific and presumptuous, and with words of rank sophistry are surely entwining us in a python-like grasp that will strangle us, to feed their coffers."

Dr. W. G. Moore, St. Louis, heartily agreed with the statement that there is no subject of greater importance than that embodied in the paper just read. He presented to the Missouri State Medical Association a paper along the same lines and feels greatly re-enforced by Dr. Billing's paper. If there is any infamy blacker than this that confronts the medical profession, Dr. Moore does not know of it. Nothing can be a greater curse than this subsidizing of medical journals. When Dr. Billings was mentioning the various companies, Dr. Moore thought he had been living in St. Louis, but, instead, he is at the other end of the canal and the stench reached him up the river. There are medical journals published to-day that should be placed in the sewer. The best efforts of medical men are demanded, and physicians should not only refuse to support, but should despise such journals as publish advertisements of these secret nostrums. He said that he could not understand how any one could trust a patient to the care of a man who would consent to give something that the hired man had taught him to use. The laborer is worthy of his hire, and Dr. Moore respects his mission, but he can not honor his employer. In a recent issue of a prominent journal Dr. Moore saw this statement regarding the treatment of gastroenteritis: "Apply warm all over the abdomen; place a cotton compress over it and bind on antiphlogistin (blue mud), and you will have no further need of doctors or medicines."

Dr. Alfred Stengel, Philadelphia, said that the nostrum evil is such an insidious one that the best informed may be taken in. As Dr. Billings has pointed out, these preparations are placed before physicians in such a way that, unless they have abundance of time to look into details, it is difficult to distinguish *bona fide* chemical preparations from untrustworthy mixtures. When the copy of The Journal containing the analysis of certain nostrums was issued, one of his colleagues asked Dr. Stengel if he knew that phenalgin was not a chemical combination. The physician in question was under the impression that it was and was greatly surprised to find that it was a mere mixture, subject to constant change and with no guarantee of its character. Dr. Stengel declared that it is important that the members of the Section on Practice of Medicine, as a body, should take a firm stand at this time. The remedy for many of the evils that affect the profession is in organized action. This association has a membership of 19,000; in addition to the members, from 14,000 to 15,000 other subscribers read The Journal; whatever attitude the members take officially and whatever point of view is supported in the editorial pages of The Journal will reach so arge a number of readers that the association may confidently hope for a removal of such evils as it attempts to correct. Dr. Stengel said that he felt, therefore, that, as a Section, they should indorse the Board of Trustees in their appointment of a "committee" to investigate and to make public the character of various substances or compounds offered as medicines and that they should indorse all that Dr. Billings has said.

Dr. James J. Walsh, New York, seconded the resolution presented by Dr. Stengel. He stated that, while he is in accord with others in blaming the medical journals, he wished to call particular attention to the fact that it is the members of the medical profession themselves who are most to blame. He said that there is no use in physicians hiding their shame behind objections made against the management of the medical journals of the country. The manufacturers of secret nostrums find only too many customers for their wares, and even in medical centers, where physicians are supposed to be well educated, the evil of prescribing secret nostrums of various kinds is very widespread. Within a few years, it has been shown that in New York City about 70 per cent. of all the prescriptions written contain some proprietary medicine that ordinarily would be expected to fall under the ban of professional use. Dr. Walsh has made it his business to secure information regarding these preparations whenever he could. On a number of occasions, when the agent of a firm has brought some new and especially seductive nostrum, hitherto unheard of, but recommended as good for nearly every ill that flesh is heir to, and a few others besides, he has inquired of druggist friends as to whether the new remedy was being prescribed or not. In nearly every case, he found that, within a month after the new remedy was so persuasively introduced by the agent, some physicians were prescribing it in their practice. This emphasizes the necessity for making the physician realize that in doing this he is selling his birthright for the proverbial mess of pottage and not always getting the pottage.

Dr. W. O. Bridges, Omaha, Neb., said that he feared that the resolution does not reach far enough. An appeal should be made to the individual physician, whether he be a member of this organization or outside it. Dr. Bridges believes that a large number of physicians unconsciously and unwittingly prescribe these secret nostrums against which we are making war to-day. He stated his belief, if physicians discontinued receiving the journals which advertise these preparations, more than one-third of them would go bankrupt. A friend of his, an editor and publisher of a metropolitan daily, recently told him that, since the expose of the secret remedies by the *Ladies' Home Journal*, his paper had suffered a loss in advertising income of one thousand dollars a month. Dr. Bridges declared that the profession is largely responsible for the conditions which exist. Dr. Moore has stated that a large number of these journals should be thrown into the sewer, and Dr. Bridges believes that still better results would be accomplished if physicians declined receiving them at all, that they might be returned to the offices from which they emanate.

Dr. J. T. Priestley, Des Moines, Iowa, said that the graduates of the various institutions in this country have had neither the time nor the opportunity to learn to dispense their medicines, and in this they certainly are weak. He mentioned the case of a bright young man who told him that he had ordered so much calomel to be placed in so much water and a teaspoonful given so often. It must be remembered that at times a very affable gentleman comes along and shows something that appeals to these young and untrained men. Dr. Priestley believes that the fault is in the teaching. If the young men were taught how to prescribe drugs as well as to give them, there will be much less of this nostrum evil.

Dr. John A. Witherspoon, Nashville, Tenn., said that too little attention is given to the actual bedside teaching of the management of disease. Most young men leave college with an imperfect knowledge of the physiologic action of drugs and imperfectly prepared to make any therapeutic application to a case in hand. Dr. Witherspoon blames the man who has the proper instruction and who takes the responsibility on his shoulders of caring for a human life without a due sense of that responsibility, and who prescribes drugs at the dictation of the traveling man. The medical man who continuously and constantly keeps on prescribing such secret remedies becomes narrow and contracted in his ability to handle disease and becomes like the negro in Mississippi who was given a new safety razor to use. Shortly after, the donor saw him and asked him how he liked his new razor, and the answer came that it was good for shaving purposes, but for marriages, social functions and funerals it was perfectly useless. Now that is the position of the physician who continuously prescribes these quack nostrums; he will become perfectly useless in the practice of medicine. Many men who publish journals are not men who can be considered as molding public or professional opinion in medicine. Medical men should continue to fight them, and also should make it appear disreputable for any journal to publish these nostrums.

Dr. Joseph M. King, Los Angeles, Cal., declared that some men with a good knowledge of the physiologic action of drugs, will yet grasp at every will-o'-the-wisp, but one of our troubles is that the rank and file of the profession have not an exact knowledge of materia medica and therapeutics. In several of the large clinics in this country which Dr. King has visited, a great deal is taught regarding diagnosis, but he heard very little concerning treatment, and it would seem that clinics are being held to teach diagnosis only, and not for the purpose of teaching therapeutics also. Of course, no man can successfully treat a case until he can diagnose it, but the patient pays for the application of what the physician knows regarding remedies. It is important that the physician should have a thorough knowledge of the weapons at hand, and then he will not be so prone to run after false gods.

Dr. A. B. Grosse, San Francisco, Cal., said that the physicians of California are in full accord with the views expressed by Dr. Billings, or it might be said that Dr. Billings has practically expressed his sympathy with the work done by the

California *State Journal* under the able leadership of Dr. Jones. Dr. Grosse disagreed with some of the views expressed that the nostrum evil flourishes through the baneful influence of the subsidized medical press and the lack of therapeutic tuition in medical colleges. Just as long as the nostrum can be found in the advertising pages of respectable and standard medical journals, the root of the evil will not have been reached. He said that this is no time to mince words and we may as well admit the error of our ways. Even the official organ of the association, THE JOURNAL of the American Medical Association, has had its advertising pages polluted by the nostrum manufacturers, and this in the face of an organized fight against the evil by the California *State Medical Journal.* Dr. Grosse urges immediately remedying these abuses. He said: "Let us purge the advertising pages of THE JOURNAL so that our hands at least may be clean."

DR. THOMAS MCCLEAVE, Berkeley, Cal., stated that all physicians in California are greatly interested in this matter. He referred to the fact that several speakers had mentioned journals published especially to cater to this class of preparations, and said that THE JOURNAL of the American Medical Association is as great an offender as any. This crusade, he said, was started by Dr. Jones, editor of the *California State Journal of Medicine*, who called attention again and again to the advertising in the columns of THE JOURNAL of the American Medical Association and was villified for so doing. Dr. McCleave said that he should like to add to the resolution offered by Dr. Stengel or to make an amendment to the effect that the Trustees be requested immediately to remove from the advertising pages of THE JOURNAL of the American Medical Association the advertisements of these nostrums. He said that, under the stimulus of criticism, much of this objectionable matter had been removed from the pages of THE JOURNAL, but that some still remains.

DR. CHARLES G. STOCKTON, Buffalo, said that Dr. Billings' paper will do good because of the fact that he has mentioned names, and it is in this that courage is shown. If the names were more frequently mentioned, carefully but strongly, the profession would soon be educated as to what is right and what is wrong. Many in the profession are not of a way to learn what they should regarding these agents. Dr. Stockton said that he believed that the committee of the Association will help if names are mentioned, if a list of objectionable preparations is published regularly in THE JOURNAL.

DR. ALFRED STENGEL, Philadelphia, added the following to the resolution he offered:

> "*Resolved*, That the Board of Trustees be requested to effect the removal from the pages of THE JOURNAL of the American Medical Association of the advertisements of any nostrums."

He thinks that this resolution should be passed. Unfortunately, all the 200,000 doctors in the country have neither the time nor the facilities for looking into the composition of objectionable medicaments. It is desirable, therefore, that THE JOURNAL should contain no deceptive advertisements and that a list of desirable or undesirable remedies should be available to the profession.

DR. NORMAN BRIDGE, Pasadena, Cal., proposed an amendment that the Trustees be *requested* to remove the nostrum advertisements.

DR. R. H. CARTER, Victoria, Canada, said that, although he is not a member of this Association, he would like the Canadian Medical Association to be informed officially of what has been done. Physicians in Canada receive many secret nostrums and much advertising matter from time to time from all the different drug houses that Dr. Billings has mentioned.

The Physician's Duty.—It is not only a physician's duty to be a good doctor, but, if he will exercise the influence he ought, he should extend his culture and make himself an intelligent force—a force which, exercised through an organized body of medical men, is bound to make itself felt. While to know one's business *may be the* whole duty of the medical man, it is not the whole duty of the cultivated physician; not the whole duty to himself, or to the standing of his profession before the public.—Hurd, in *Buffalo Medical Journal.*

SYNCYTIOMA MALIGNUM.*

LAURA HOUSE BRANSON, M.S., M.D.
IOWA CITY, IOWA.

DEFINITION.

In some of our latest works on pathology and gynecology we find this growth mentioned and thus defined:

Syncytioma malignum is a malignant neoplasm exhibiting the morbid physiologic characteristics of sarcoma and carcinoma.[1]

It is a degenerative malignant disease of the sarcomatous type originating in the decidual structures of the pregnant woman and tending to a rapidly fatal issue.[2]

It is a hemorrhagic tumor, a malignant growth developing in the body of the uterus, which belongs to the sarcoma group, and to a variety never before observed.[3]

It is derived from the syncytium, and the syncytium is the undifferentiated embryologic tissue, and the tumors derived from it are neither epithelial nor sarcomatous.[4]

It is a peculiar neoplasm of the uterus, peculiar in that it occurs only after pregnancy, in that its parenchyma is derived from two forms of cells, and, finally, in that its origin is in the fetal tissue and its development in the maternal organism.

I have found that but a comparatively few of the works recently published to be used as text-books in our medical colleges even mention this as a distinct neoplasm; this is a remarkable statement in view of the fact that there are now on record about two hundred cases of this tumor formation as differentiated from all other growths. Sänger began the record in 1888; Pfeiffer followed with a case in 1889; Sänger reported 12 cases in 1893; Bacon reported a collection of cases in May, 1895; Williams, 27 in August, 1895; Ladinski, 132 in April, 1902; Bandler, 150 in August, 1902; Teacher, 188 in August, 1904; since then I have noticed reports of the following cases: Metcalf and Swafford,[5] 1904, one; Wallert,[6] 1904, one; Krukenberg,[7] 1904, one; Bland,[8] 1905, one; total, 192.

There is no doubt that there have been other cases diagnosed, but not reported; and, again, other cases that have passed unrecognized because of the lack of facility to conduct properly examinations leading to a correct diagnosis.

NOMENCLATURE.

Those who reported these cases or who have contributed otherwise to our literature on this subject have used the nomenclature that seemed to them an exposition of their personal opinions as to the origin of this growth. Consequently, we have a confusion of terms, as carcinoma syncytial, malignant placentoma, sarcoma chorii, epithelioma serotinale, deciduoma malignum, deciduo-carcinomæ, sarcoma-deciduo-chorii-cellulare, chorioepithelioma, syncytioma malignum, etc.

The term syncytioma malignum is, in my opinion, the best designation for this particular neoplasm, in that it immediately fixes one's attention on the growth with its distinctive features, and in that it shows without the possibility of a doubt its derivation and its location, the conditions under which it must exist, as well as its relation to its host.

---

DERIVATION AND HISTOLOGY.

According to Marchand's[9] theory, which is now generally accepted, this neoplasm is originally derived from the fetal ectoblast or trophoblast. Following the implantation of the fertilized ovum on the maternal endometrium, the trophoblast develops villi which penetrate the endometrium, reaching the maternal network of blood vessels from which the ovum is nourished. Covering these chorionic villi is found an epithelium consisting of two layers; the outer, the syncytium; the inner, Langhans' layer of cells, which Langhans considers mesodermal in origin, syncytium resulting when the blood comes in contact with fetal cells. This syncytium consists of protoplasmic masses which are the product of blood cells—the nuclei, being the changed trophoblastic nuclei. The derivation of these layers forming the covering of the chorionic villi is now the point on which those who have made the most exhaustive investigation along these lines disagree. Bandler,[10] who has studied the subject of placentation in the lower animals, concludes thus: "Clear in almost every detail, a trophoblast formation, consisting of an inner layer of separated cells and an outer or plasmodial layer, such as is found in the placental development of animals, is present in the human placentation." Many noted authors across the waters contend that this chorionic epithelium is derived from the deciduæ; consequently, that this growth is of maternal origin. Some authors have urged the opinion that the layer of Langhans disappears during pregnancy and that the outer layer remains. However much diversity of opinion there may be as to origin of these two layers covering the chorionic villi, it is universally agreed that this neoplasm takes its origin in these layers, and demonstrations have been made which leave no doubt that the protoplasmic masses found in this growth originate in the syncytium and that its individual cells are identical with those of Langhans' layer.

DEVELOPMENT.

This neoplasm is usually one of rapid development, running its course in a few days or weeks, although it may remain in a latent or quiescent condition for months after impregnation. I want to emphasize the fact that this malignant growth may develop during, as well as following, pregnancy.

In April, 1902, Ladinski[11] reported over a hundred cases showing that occurrence of syncytioma malignum or deciduoma malignum had taken place in from one week to twenty months after termination of pregnancy. In the same year Noble[12] reported a case examined microscopically by Dr. McFarland in which thirty months had elapsed between the last puerperium and the extirpation of the uterus for this neoplasm. In this case twenty months had elapsed before the first symptoms had manifested themselves.

In 132 cases collected by Ladinski[11] the average lapse of time was eight weeks after mole pregnancy; seven weeks after abortion, and five weeks after labor at term. Dorland,[13] in a report in a series of cases of this disease, says: "Fifty-nine and six-tenths per cent. manifested symptoms either during labor or within four weeks of that time; in 78 per cent. death occurred six months from the appearance of the symptoms.

LOCATION.

The usual location for this neoplasm is on the inner surface of the uterine wall, at the placental site; it may extend outward from the endometrial[14] surface or it may be intramural.

MICROSCOPIC APPEARANCE.

This growth occurs single or multiple, and it may be nodular or pedunculated. In size it is variable; it may be a small tumor or one filling the entire cavity of the uterus; in one instance, the weight is recorded at seven and one-half pounds;[15] in its earlier history it is a somewhat firm mass of a pinkish-gray color, which later on becomes infiltrated by blood or dotted with circumscribed hemorrhagic areas, changes to a soft fragile mass, usually sharply defined from the muscularis. It is prone to ulcerative processes, and it may become enucleated and escape from the uterine cavity in the lochial discharge.

MICROSCOPIC APPEARANCE.

Some authors have asserted that a greater part of this tumor is made up of degenerated muscle cells; others oppose this, claiming that the cells formed in the muscles are in reality choriomatous cells which have invaded the muscularis by the process of infiltration. In a microscopic examination of this growth protoplasmic masses are found, which, because of their arrangement, sometimes assume a striated appearance; then, again, they simply form irregular masses; these masses are homogeneous and contain nuclei which readily imbibe stain, while here and there throughout these masses are found vacuoles, some of which are found to contain blood cells; these constitute the syncytium.

Aside from this structure are found cells with boundaries well marked, and distinct muscular division, all together forming an atypical representation of normal placental tissue. Another element sometimes present in this formation is the chorionic villi; Reed claiming that these may be found entire, but marked by aplastic features. The proportion of these elements may vary in different stages or in different parts of the same neoplasm; so, also, may different degrees of degeneration be found. Bland[8] claims that the tumors containing the chorionic villi do not have so great a tendency toward malignancy.

METASTASES AND SECONDARY GROWTH.

This tumor is one in which metastases occur quickly and early in the history of its formation; this is one of the most distinctive features of the syncytioma malignum.

When we study the subject of placentation, its normal activities resulting in the giving up of nourishment from the maternal circulation for the vital processes in the fetus, we do not wonder at this property of metastasis, carried on by means of these same maternal blood vessels from these same elements or tissues; which tissues, instead of carrying out Nature's design to make the pregnant as well as the parturient condition a physiologic one, have by some means been thwarted in the performance of their legitimate work. Metastasis takes place almost entirely through the blood vessels. Gebhard and Menge[16] reported cases in which the lymph channels transmitted the material forming the secondary growth. This may have taken place in the later stages. The site for the formation of these secondary growths may be in any tissue, however remote, as well as in tissues adjacent to the primary location. The secondary formation may be the first manifestation of the disease, and it may equal or exceed the primary tumor in size. In gross appearance, as well as in histologic features, it is identical with the original growth. Of 52 cases reported by Dorland, the secondary growths were found in 70.76 per cent. Relative frequency of occurrence in the various organs he computed as follows: In lungs, 78.37 per cent.; vagina, 54; spleen, 13.5; ovary, 13.5; kidney, 13.5; liver, 10.8; broad lig., 10.8; pelvis, 10.8; brain, 5.4.

DIAGNOSIS.

The prime factor in the diagnosis of this disease is that it is a tumor formation dependent for its origin on impregnation. It has been shown that it may occur after delivery at full term, abortion, or hydatid mole pregnancy. The first symptom usually manifesting itself is hemorrhage that will not yield to any usual methods for relief. A hydatid mole formation may be found in the uterus; this may be a guide to a correct diagnosis. Findlay,[17] in his clinical deductions from 210 reported cases of hydatidiform, found that in 25 per cent. of mortality, of these 210 cases, syncytioma malignum claimed 16 per cent.; other statistics show that 50 per cent. of all cases of syncytioma malignum follow hydatidiform mole. Following the hemorrhagic discharge, there may be a foul watery discharge, as the necrotic conditions take place; pain may be present, later referred to the pelvis; headache not localized, cachexia, anemia.

On examination, the uterus may be found enlarged and soft with os patulous, on manipulation, tumor may be localized; a specimen should always be subjected to an examination under a microscope. In themselves the clinical symptoms are not pathognomonic, but in combination with history of patient, her age, her previous parturitions, confirmed, as a rule, beyond doubt by the microscopic examination of the specimens obtained, the diagnosis should be correctly made.

COMPARATIVE DIAGNOSIS.

All modern writers who have thoroughly studied the different phases of this growth, and who now consequently recognize the distinctive morphologic and pathologic features, do not hesitate to call it an intensely malignant neoplasm, and to place it in the list with other malignant tumors of the uterus. Reed classifies malignant neoplasm of the uterus thus: 1. Syncytioma malignum; 2, adenoma uteri; 3, sarcoma uteri; 4. carcinoma uteri; 5, exceptional cases.

In making a diagnosis, these four neoplasms must be considered, as well as remnants of abortion; the main distinctive features may be tabulated thus:

Adenoma Uteri.

1. Malignant degeneration of gland structure.
2. Long duration.
3. Least active, less pain, less hemorrhage.
4. Papillomatous growth or growths.

Sarcoma Uteri.

1. Developed from embryonic connective tissue.
2. Has no arrangement of cells.
3. Has intercellular reticulum.
4. Blood vessels are abundant, thin walled, and lie between cells.
5. Metastasis by blood vessels.
6. Peculiar to young in life, before age of 35 years.
7. Slight tendency to ulcerate.

Carcinoma Uteri.

1. Developed from epithelial cells.
2. Cells arranged in alveoli.
3. No intercellular tissue, same being arranged about groups of cells.
4. Blood vessels not abundant, and lie in the stroma, not between the cells.
5. Metastasis by lymph channels.
6. Occurs generally in middle and advanced life, after 35 years.
7. Great tendency to ulceration.

Remnants of Abortions.

1. Shaggy appearance due to composition of slender threads.
2. Not friable.
3. Placental cells with nuclei, always present, isolated by wide zone of protoplasm.

Syncytioma.

1. Dependent on pregnancy.
2. Fifty per cent. of all cases follow hydatidiform mole.
3. Average age, 33 years.
4. Developed from chorionic epithelium.
5. Disease of child-bearing period.

COMPARATIVE MALIGNANCY.

In comparing this neoplasm of the uterus with other malignant new growths of the same locality, we claim that it outranks all others in the degree of the severity of the malignant manifestations, because of its unheralded attack on the part of the human organism that has but a short time previous been called on to perform a function that has no parallel among all of the many and varied functions of our economy; because of its presence made known only when it is already well developed; because of its early proneness to rapid metastases; because of its great danger dependent on the site selected by these secondary growths; because of its short history; because of its almost certain tendency to fatality from exhaustion, hemorrhage, sepsis, etc.

REPORT OF CASE.

Patient.—Mrs. A., aged 31 years; primipara, married two years, family history negative. Husband has syphilis in tertiary stage.

History.—Low vitality, sedentary habits; chronic constipation, menses regular, but scant, never painful, but accompanied by intense malaise. The first six months of gestation were uneventful. During the seventh and eighth months there was persistent headache, which at times became unbearable, patient relying for its relief on household remedies and headache powders obtained at drug stores, never at any time consulting a physician. At the end of the eighth month of gestation I was called and found the patient in labor, with os dilating slowly; labor continued thirty-six hours; pains far apart, anemic and manifesting hysteria throughout the period; no other marked clinical symptomatology except dilatation of both pupils. At the end of thirty-four hours I made a forceps delivery which was accomplished in thirty minutes with no outward effect on the patient; child still-born, small and poorly nourished. While inserting one blade of the forceps I came in contact with a nodular mass, some four inches in length or diameter, on the inner uterine surface, quickly removing a portion I placed it in alcohol to examine later. In thirty minutes placental delivery was finished; hemorrhage profuse; thin with disagreeable odor. I remained with patient four hours because of her exhaustion. On my return thirty hours later I found the patient exhausted, pupils in same condition of dilatation, lochia foul. A sudden severe attack of tonsillitis kept me confined to the house for ten days; consequently, the subsequent history could not be followed by me. Patient died, evidently from exhaustion, three days after delivery. I subjected the section of enucleated portion of suspected tissue to a microscopic examination, using the Mallory and Wright technic, the clinical history of the case leading me to suspect neoplasm dependent on pregnancy. I could not detect villi in sections examined, but recognized cloudy masses without cell walls containing two or more nuclei, which readily imbibed stains, in combination with clearly defined cells in different stages of proliferation or degeneration; cells of varied size with karyokinesis manifested; blood cells were present, as were also hemorrhagic spaces. The diagnosis was syncytioma malignum.

---

[16] Menge: Ueber Deciduo Sarcoma Uteri, Zeitschrift für Geb. and Gyn., xxx.

[17] Findlay: Hydatidiform Mole, Trans. Gyn. Soc., Chicago, 1903.

The peculiarities of the case were that the tumor formed preceding delivery of fetus, the persistent severe headache, the well-marked dilatation of pupils showing possibility of metastasis into brain tissue.

Davis and Harris[18] reported a case of this neoplasm in a multipara two months after parturition with severe unlocalized headache as the one prominent symptom; at the autopsy, syncytial tumors were found in the brain, lungs, kidneys and liver.

Dean, professor of ophthalmology in the Iowa State University, states that a frequent result of brain tumor is dilation of the pupils with slow reaction to light; frequently the pupils are unequal. A choked disc should also be present. A tumor in any part of the brain may produce this condition, but those of the cerebellum most usually are the cause.

There are instances recorded in which hydatidiform mole formation and pregnancy have existed in the uterus simultaneously with delivery of a healthy child at term.[19]

Depaul remarked: "All the world knows that the celebrated Beclard was the result of a hydatidiform pregnancy." He urges the possibility of a viable child being born as a reason for abstaining from active interference.

Carcinoma and pregnancy may coexist in the uterus. I will briefly refer to Cohnstein's[20] 134 cases prior to 1873, Theilhaber's[14] 165 cases from 1873 to 1893, while Noble[21] has found 165 cases recorded since 1886. Further, 61 per cent. of Cohnstein's cases went to term; in 36 per cent. of them the child was born alive, while in 47.2 per cent. of Theilhaber's cases the child was born viable.

Polano[22] claims that the tumor malignant epithelioma follows or may coexist with hydatidiform mole.

I claim that malignant epithelioma or syncytioma may coexist with pregnancy.

CONCLUSIONS.

"It is the accumulation of our experiences that makes our empirical knowledge at last a fact."—Munday.

In my case just reported, could the syphilis of the father have had anything to do with the formation of this malignant neoplasm in the mother? We have abundant proof all about us of the unlimited influence that the fertilizing element may exert on the ovum; further researches in biology, physiology and chemistry may throw some light on this interesting study.

Again, the growth of these elements that make up this tumor depend on the maternal nourishment; if the maternal circulation is disturbed or impoverished by a constitutional disease, such as syphilis, could this not result without the syphilitic germ being manifested in the new growth?

The power of the maternal blood has been demonstrated in its action on the trophoblastic cells, changing them to syncytium; could not this maternal blood by a slight relative change in its own elements cause an undue proliferation and consequently a degeneration from lack of proper supply of blood in these very elements, and this cytolysis result in a neoplasm with the distinctive features of this one?

Fifty per cent. of the cases of hydatidiform mole are followed by syncytioma malignum. From this statement one would deduce the opinion that the same cause that produces the hydatidiform mole must necessarily be an etiologic feature in the production of syncytioma malignum. There have been many and varied opinions recorded as to the etiology of hydatidiform mole, but as yet none have proved satisfactory.

In the evolution of theories which have been recorded from time to time as to the real nature of hydatidiform mole, beginning with that of Hippocrates that it was thickened sperm; later Litre's view that it was due to the hypertrophy of the Nabothian glands and down to the view promulgated by Virchow[23] that it was due to a myxomatous degeneration of the chorionic villi, we have reached the conclusion held by Marchand[24] and the most generally accepted at the present, viz.: hydatidiform mole is due to a proliferation of the syncytium and of Langhans' layer, accompanied by a dropsical condition of the chorionic villi.

Findlay[25] claims that this condition results from a disturbed maternal circulation causing these elements to penetrate more deeply into the decidua where nutrition is adequate.

Bacon[26] continues thus: "The hydatidiform mole, which is very frequently found in these cases, predisposes to the growth of the tumor, deciduoma malignum, by diminishing the resistance of the uterine tissue to these elements." Could one not find cause for this in the continued vitiated blood supply of the syphilitic subject?

We hope for a speedy solution of the problem as to the causation of this neoplasm; a solution which in all probability will settle the question of etiology for other malignant growths of the uterus, as well.

We look to biology to focus its research on the cell processes and to differentiate between the normal and the pathologic changes taking place within the cell; the study of the cause of cell proliferation opens up another avenue full of hope; the greater our knowledge of cytomorphoses the clearer will be our understanding of cell proliferation. We look to chemistry to show the natural cell constituents and to differentiate between these and the products of the metamorphoses taking place in the neoplasm.

Cell growth is controlled by certain stimulating and inhibiting influences: knowledge of these may explain many of the now unknown phenomena, including the retrogressive metamorphoses that are attributed to the cels of this tumor.

DISCUSSION.

Dr. W. O. Henry, Omaha, said that hemorrhages following abortion or labor, and the rapid growth of the tumor and its early metastasis, should lead the physician to suspect that it is of malignant character. This is a particularly fatal disease and rapid in its course. Not much can be done in such cases unless the diagnosis is made in the very beginning and then a radical operation done. Dr. Henry disagreed with Dr. Branson that this disease might be a manifestation of syphilis; syphilis is, indeed, a terrible disease, but he believes that too many things are laid at its door. Whenever a physician is confronted by a condition which he can not explain he is apt to conclude that some member of the patient's family had syphilis as a primary cause of the trouble. This, Dr. Henry believes to be a serious mistake. Physicians should always seek for a scientific rather than ascribe so many of these obscure conditions to syphilis, simply because they can not be explained on other grounds.

A STUDY OF THE BONY PELVIS IN ONE HUNDRED AND FIFTY CASES.*

EFFA V. DAVIS, M.D.
CHICAGO.

In reviewing my work in pelvic measurements in the past five years, some general impressions were borne in on my mind relative to the frequent causes of deformities in the cases handled and the not infrequent difficulty encountered in the normal pelvis, which moved me to take some notes in regard to childhood, puberty, family and general habits, to verify, if possible, the impressions left by my daily work.

The cases in which sufficient notes have been taken to permit of an accurate report are those personally attended by me, though often assisted by medical students and internes, and are made up of private and dispensary cases in about equal numbers. Seventy-three have been attended in their homes and 77 in the hospital, 150 cases being considered.

In studying the pelvic measurements in this series of cases a diagonal conjugate of 11.5 cm. or over has been considered a normal pelvis. A pelvis has been considered generally contracted when all external measurements were diminished with the diagonal conjugate, 11.5 and less, and simple flat with a diagonal conjugate of 11 cm. and all external measurements normal.

Rachitic pelves were distinguished by the narrow conjugate and flaring brim, as shown by the decrease of distance between the crests and spines.

Over 82 per cent. of the cases (124) were normal in measurements, and somewhat over 17 per cent. (26) were deformed.

In classifying the deformities eighteen or 69.23 per cent., were generally contracted. Four, or 15.38 per cent., were simple flat and four rachitic.

In the deformed cases, 16, or 61.54 per cent., were normal deliveries, and 10, or 38.45 per cent., were operative. The operations included mid-forceps twice, high forceps twice, extraction twice, version and extraction three times and Cesarean section once. The indications for operation were the bony pelvis and malpositions.

Of the normal cases (124), 112 were delivered spontaneously, and 12, or 9.67 per cent., were operative.

Classifying the operative work in the normal cases, low forceps was applied once, mid-forceps six times, high forceps twice, extraction twice, version and extraction once. These operations were indicated by an oversized child four times, inertia with large child three times, toxemia once, eclampsia twice, transverse presentation once and breech once.

In comparing the size of the child at birth with the size of the pelvis—those born of normal cases averaged 7.94 pounds, and those from deformed cases 6.43 pounds—making an average of one and one-half pounds in favor of the normal pelvis. It is to be regretted that an accurate weight and height measurement was not kept of the mothers, but only a portion had been noted, not enough to carry out a correct report.

A study of 135 cases was made to determine the relation, if any, of the child's average weight at birth to occupation and diet in the mother during pregnancy.

Eighty-eight mothers were found inactive and abundantly well fed. The average weight of their infants at birth was 8.06 pounds.

Thirty-eight mothers were compelled to take active exercise, with plain but wholesome food, and the average weight at birth of their infants was 6.7 pounds. Nine mothers were ill with chronic diseases during pregnancy, and the average weight of their infants was 5.77 pounds. These cases were studied individually, and about half were attended in the hospital and about one-half in their own homes.

Many patients were kept in the hospital for several months before labor, but those that were charity charges were obliged to do active housework and they were considered as active patients on plain but wholesome diet.

It soon became noticeable that the active patients had short easy labors, with moderate weight in the child, while the inactive private patients that waited with us, and whose appetite was tempted by friends and relatives, often had the most tedious labors, with oversized children.

As we were so often met with reproachful surprise when a charity applicant was informed that she must work for her board, both she and her friends thinking because she was pregnant that it was cruelty to expect her to do active housework, we determined to study the matter more closely and began the notes which furnish these figures.

A temperature and pulse record, with observations as to excreta, is taken daily of all waiting and working patients, and a patient showing any evidence of toxemia is not permitted to work, but is placed in bed and diet restricted.

An abdominal supporter is advised in all cases of pendulous abdomen, but when there are no unusual symptoms the patients are encouraged to do an active day's work up to the time of delivery, and private patients are directed to walk two or three miles in the open air daily.

The nativity of the patients gives 105 American, or 70 per cent., and forty-five foreign born, or 30 per cent.

The deformed patients show twenty American and six foreign. A preponderance of the deformities were of the generally contracted type, of which there were twenty American and two foreign; simple flat, three American and two foreign; rachitic, two American and two foreign. The foreign cases were classified as follows: German, 10; Italian, 7; Irish, 7; Scandinavian, 7; Russian Jew, 6; Austrian, 5; English, 2; Dutch, 1. This gives 19 per cent. of American women with deformity and 13.33 per cent. of foreign. Though the number of cases is rather limited for accuracy, this is evidence that European women may not have, as has so long been believed, a larger number of contractions than our own country women.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Some notes have been made as to education and attendance in school. All foreign-born women were illiterate (18) or of common-school education (27), not being in school after the twelfth or fourteenth year. Their menstrual period began as an average at the fourteenth year, and their deformities were divided equally between the three varieties. Of the 105 American-born women, twenty-five were of high-school, academy or college education. Seventy-five had a common-school education, being in school until the fourteenth or sixteenth year. Five were illiterate. Their first menstrual period average was at the fourteenth year.

In comparing the normal with the deformed cases, it could not be determined that application to school duties had anything to do with the growth and development of the bony pelvis; neither had such diseases of puberty, as chlorosis or chorea, malaria or other chronic wasting disease which attacked the body after the bones had once received a normal childhood start.

In looking for causes of pelvic deformity in this series of cases, the family history and childhood history was carefully noted.

Artificial and improper breast feeding is so commonly the cause of rickets that the four cases of rachitic pelvis were easily classified under that head.

The simple flat cases could not be assigned to any one cause, but occurred in cases where "delicate in childhood" was a common statement.

The parental history so far as obtained of all deformed cases was interesting, confirming the theory that contractions of the general type is a form of degeneracy.

The following is a list of the diseases mentioned as affecting one or both parents of the twenty-one patients out of twenty-six deformed: Inebriety, seven times; rheumatism, twice; heart and kidney disease, twice; tuberculosis, three times, and syphilis once. Two had a negative history and three were not noted.

CONCLUSIONS.

Deformity occurs often enough to make pelvimetry a practical part of the examination of pregnant women.

Generally contracted pelves form by far the most common deformity in American women, though the rachitic pelvis is often present in those who have been artificially or imperfectly breast fed in infancy.

Inebriety in the parents is the most constant element toward degenerate types in the deformities studied.

The size of the infant can be regulated by diet and exercise if carried out strictly for a proper time during the last three or four months of pregnancy.

SUMMARY OF NOTES.

Number of cases studied 150

Primipara, 76; multipara, 74; attended in hospital, 77: attended in homes, 73.

Normal pelvis 124, or 82.66 per cent.
Deformed pelvis, 26 or 17.35 per cent.
Generally contracted, 18, or 69.23 per cent.
Simple flat, 4, or 15.38 per cent.
Rachitic, 4, or 15.38 per cent.

NATIVITY.

American ....105, 70 per cent.
Foreign .... 45, 30 per cent.

DISCUSSION.

DR. W. O. HENRY, Omaha, said that the number of cases is too small for accurate statistics. The report is instructive, however, because of the careful tabulation, and it is hoped that Dr. Davis and others will continue this work until the profession has a sufficiently large number of cases on which to base more reliable statistics.

DR. J. H. CARSTENS, Detroit, said that there was a time when physicians believed that deformed pelves were confined to the poorer classes, but more and more are developing in women of the better classes. Among the poor they are the result of bad environment and poor food, but among American women these factors usually do not prevail; hence some other factors are responsible.

DR. EFFA V. DAVIS said that perhaps too luxurious habits are permitted in pregnant women. In discussing the subject with Dr. Davis, many physicians have said that is impossible to do anything to limit the size of the child, but Dr. Davis thinks that this can be done. An infant that weighs ten pounds at birth is too large. Women who are active and careful in diet do not have such large babies, although they can have average well-nourished infants. Of course, once in a while a woman who has been well fed and idle is delivered of a small baby, and occasionally a poorly fed, hard-working woman will have a large child, but that is not the rule, and there may be other factors affecting the results in these apparent exceptions.

Meteorism in Pneumonia.—H. Schiller considers meteorism of considerable degree one of the worst prognostic symptoms in pneumonia. When it is distinct, he says, it indicates a severe and often deadly course.—*American Medicine.*

THE PSYCHOPATHIC MANIFESTATIONS OF THE NON-INSANE PSYCHONEUROSES.[*]

JOHN PUNTON, M.D.
KANSAS CITY, MO.

The active, enthusiastic investigation and widespread interest in the nature and character of the insanities deserves most cordial consideration and support.

Heretofore the study of psychiatry has been more or less divorced from practical clinical neurology, while to the average general medical practitioner it was almost a sealed book. The tendency of modern medical progress, however, is such as to bring psychiatry into closer relationship with general medical practice by furnishing the general practitioner with more accurate scientific knowledge concerning the clinical aspects of insanity and its allied neuroses.

At the recent meeting of the American Psychological Association, the scientific program beautifully illustrated the practical trend of psychiatry in America at the present time, for it is interesting to note that the burden of the themes presented by the leading alienists in their papers and discussions was intended to enforce at least three practical truths:

1. The great necessity for a more thorough knowledge of insanity by the general medical practitioner.
2. The marked and prompt curability of insanity in its incipiency.
3. The extreme susceptibility of insanity to prevention.

Moreover, another important fact was also not only recognized but duly emphasized, viz., that, while insanity is primarily a psychosis of the highest order, yet there are a number of morbid mental states which, while showing a marked kinship to insanity, are not usually so regarded by the general medical profession.

These include such conditions as neurasthenia, hysteria, hypochondria, certain forms of epilepsy, the precocious dementias, paranoia, melancholia, mania, manic-depressive insanity, and the toxic and exhaustion psychoses. Many of these morbid states follow acute fevers like typhoid, pneumonia, la grippe, and other infections, or become the sequelæ of alcoholism, syphilis and other poisons, all of which in their clinical syndrome may present varying degrees of delirium, confusion and stupor.

Such psychoneuroses. as a rule, however, first come under the observation of the family physician, who, unfortunately, often fails to recognize their true psychologic significance until the obsession, impulsion, or imperative concepts and other mental manifestations accompanying them become so conspicuous and striking that the opportunity for the patient's recovery is thereby greatly lessened.

The extreme relational importance of these various so-called nervous disorders with insanity, while having been referred to occasionally in medical literature and now duly accepted by us, are not so well understood by the general medical profession as their seriousness justly warrants.

The special object of this communication is to emphasize the close kinship which they sustain to the great psychoses by their progressive transitional nature illustrated by their psychopathic manifestations.

To the average general practitioner the diagnosis, prognosis and treatment of the various nervous diseases become at once the most formidable clinical problem with which he is confronted. It is not strange, therefore, that in the incipiency of the states referred to he should fail to recognize their true psychologic significance or properly to interpret their more serious, morbid, progressive, incurable tendencies.

To the family physician such morbid conditions as neurasthenia, hysteria, hypochondria, the precocious dementias, paranoia, melancholia, and allied states are often recognized and diagnosticated as purely neurotic disorders, and even when the mental symptoms are very pronounced he fails fully to appreciate their true psychopathic significance. Hence what was formerly, and even to-day, regarded by many as a pure neurosis is now known by us to constitute a true psychosis. In making this differentiation between the neuroses and psychoses, however, and thus defining their special pathologic significance, much depends on our use and understanding of the term insanity. Dr. Dewey has recently shown that, according to views now generally prevalent, "if there be a dividing line between the neuroses and psychoses, insanity exists on both sides of this line." Hence, nervous prostration and hysteria are often nothing more nor less than a polite misnomer for actual insanity. Recognizing, however, that in all such psychoneurotic states there is a marked admixture of rationality, and that even in many the intelligence may be far above the average standard so that when the term insanity is even hinted at in their connection, much less applied, it necessarily meets with a vigorous, and perhaps just objection.

This opposition also seems the more feasible when we remember that associated with the purely mental phenomena various somatic disorders and disturbances of the different mechanisms of the nervous system, more especially those of the visceral and sexual organs, are often present in all degrees of intensity. Moreover, these may account, to some extent at least, for the clinical symptom-grouping and therefore should also be duly considered in not only their nomenclature, but in any classified system of their nosology. It is not surprising, therefore, that the many attempts which have been made by different authors to furnish a term to express the pathologic condition underlying such states—the same to be in strict accord with scientific medical nosography —should fail to overcome the serious objections to such terms as hysteria, neurasthenia, phrenasthenia, and insanity, when applied to these psychoneurotic states, as such terms are not only inappropriate, but often misleading, and, therefore, subject to criticism, and even by some regarded as bitterly offensive.

The term "psychosomatasthenia," therefore, suggests itself to me as being essentially appropriate and applicable to all such morbid conditions. Like its many predecessors, it is subject to some objections as, for instance, its length, yet it has the redeeming virtue of indicating not only the seat, but also the nature and character of the malady, thereby encompassing the two most essential features in every diagnosis, while its general use would readily and satisfactorily overcome the many objections to those terms now in use which give offence.

While all such psychoneurotic states are attended with every degree of physical infirmity which are chiefly illustrated in disorders of nutrition, yet we contend that the various somatic changes are primarily and essentially the result of weakened inhibition or lack of nervous innervation due to some defect of perversion of the higher cerebral nerve centers, whether this disturbance is in response to their protracted functional activity or the reverse of this, or to some hereditary effect or even toxic agent. Such morbid influence, however, in the early stages is undoubtedly capable of being readily repaired or adjusted by appropriate means, but if unduly prolonged without such treatment the lesion of necessity becomes more fixed and pronounced, and may even prove altogether irreparable in spite of all temporary expedients. The clinical study of the various psychopathic manifestations of the non-insane psychoneuroses and their special pathogenic significance, therefore, may be found most useful in aiding in their diagnosis, prognosis and treatment..

---

[*] Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

It is now a well-established scientific fact that neurasthenia, hysteria and allied states are simply the forerunners of actual insanity. Indeed, in the vast majority of instances such neurotic conditions constitute its earliest or incipient stage. Moreover, all authorities agree that incipient insanity is attended with physical and mental changes that are indicative of nervous exhaustion or nutritional defects which thus form its physical basis.

Increasing knowledge of the etiology and pathology of these psychoneuroses also emphasize the intimate relation existing between them besides endorsing the significant fact that insanity is but a different phase and further development of the same morbid process which underlies their protean clinical manifestations. Independently, therefore, of the purely physical phenomena that attend such morbid states, the psychopathic or mental symptoms demand our most earnest consideration, for on these hinge not only the diagnosis, but also the prognosis and treatment.

That the conditions of mental aberration comprised in these borderland and episodic states should present a wide range of symptoms of equally varying gravity is readily understood; hence we find them presenting every degree of seriousness in proportion as they involve the functions of the higher mental faculties. While the intelligence may not be materially implicated, yet there is in all such individuals a decided nervous weakness, or lack of inhibitory control which seriously mars the normal power of the will, weakens the judgment and intellect, and excites or depresses the emotional attributes. As the highest function of the nerve cell its power of inhibition or that energizing force which not only directs, but also restrains and controls the various mechanisms of the nervous system, it follows as a logical sequence that this supreme physiologic endowment by virtue of its late evolutionary development readily responds to the well known biologic law that those nerve centers which are the latest evolved are the least organized and consequently more vulnerable to all kinds of morbid influence.

Whatever, therefore, may be the cause of the various psychoneuroses, whether congenital or acquired, or due to hereditary defects, stress of all kinds or the result of some toxic agent, their first effect is seen in a lack of normal inhibitory control of the directing mental forces of the individual, which in turn produces nutritional changes that greatly weaken the various functions of the nervous mechanism.

With the higher inhibitory and controlling power impaired or abolished the instinctive inclinations also dominate and become highly exalted, varying with the peculiar idiosyncrasy of the individual. These are also attended with more or less headache, neuralgia, feelings of oppression, insomnia, unpleasant dreams, mental apathy, defects of memory, marked irritability, moroseness, and vacillating emotional apprehensive states, all of which are psychopathic manifestations of an unstable nervous organization.

"Blandford[11] has demonstrated that the most notable clinical psychologic feature observed as a result of lessened inhibition is an increased activity of the lower instincts or impulses normally held in check by the highest mental faculties. These, he claims, pertain chiefly to egoism or self-conscious emotional states, which owing to their lack of proper inhibition, are allowed to become unduly ascendant and even exalted.

Like all physiologic qualities, however, the normal power of self-control exists in every degree of strength and weakness in different persons. The same is true of the mental disposition or temperament and other sensibilities, all of which are modified and even largely controlled by the exercise of the will and judgment, while these faculties are again subject to the powerful influence of heredity, environment and education, together with other external conditions.

The psychopathic manifestations of psychosomatasthenia, therefore, consist in differing degrees of impairment of these higher psychical functions and are said by Regis to be fundamentally dependent on some lesion of the will. In their clinical aspects, however, they present every degree of exaggeration of the normal intellect, emotion, and will of the sufferer, thus comprising all forms of peculiarities, oddities, eccentricities, notional absurdities, obsessions of every kind, and even criminal tendencies, all of which at times are so cunningly concealed, or possibly even rationally defended, that their true nature and character are often overlooked, or their progressive, transitional, incurable, and even vicious, tendencies wholly disregarded.

Except in the most pronounced developments of these conditions, such persons are seldom found in our insane hospitals. They usually appeal for relief to the family physician, however, who is often at his wits' end to know how best to provide for his vacillating and even unruly nervous patient.

As a result of the weakened mental directive power due to lessened inhibition and consequent lowering of neuronic activity a general feeling of weakness or bodily illness is thus engendered, which attracts the attention of the patient to himself and forms the basis of morbid introspection with all degrees of apprehensive anxiety, suspicion and morbid fear. This again leads to the development of despondency, petulance, irritability, selfishness, impatience, hilarity, indecision, doubt, mental confusion, stupor and vacillating, impulsive conduct, all of which are marked features in the incipient or formative stage of insanity.

These psychopathic manifestations of the non-insane have been variously designated by the different authors as obsessions, besetments, imperative concepts, impulsions, and fixed ideas, all of which, however, consist of a general feeling of anxiety, doubt, or fear, which may lead later to impulsive acts like suicide and homicide.

As an aid to their diagnosis Regis has ably divided them into three classes, viz:

I. These characterized by indecision of which all kinds of morbid doubts are typical.

II. Those characterized by all kinds of morbid fears constituting the various phobias.

III. Those characterized by morbid propensities or irresistible impulsive tendencies.

Each of these is again subdivided, for instance, Ball has divided the first class, or doubters, into five different classes, according to the nature of their predominating ideas, hence we have:

1. The metaphysicians, who are especially haunted by abstract questions of all kinds, such as doubts concerning Heaven, hell, the world, the Deity.
2. The realists who constantly revolve in their thoughts the lower and base details of objects, such, for example, as the conformation of the genital organs, copulation, etc.
3. The scrupulous, whose doubts pertain to forms of religion, such as accusing themselves of committing the unpardonable sin, or of some theft.
4. The timorous, who are fearful of committing some indelicate action by even allowing their clothing to come in contact with others, etc.
5. The counters, whose doubts are manifested under the form of irresistible enumeration. Such patients never get through counting different objects, such as the door knobs, the houses on the street, or their number.

The second class, or those suffering from morbid fears or phobias, is divided into three sub-divisions:

1. Those who have a morbid fear of all kinds of objects, its expression is extremely varied, and may involve such articles as glass, knives, pins, guns, thunder, flowers, besides certain kinds of food and drink.
2. Those who have a morbid fear of places, elements of diseases. Such patients are morbidly fearful of high places, bridges, streets, churches, theaters, rivers, besides a dread of all kinds of diseases, such as heart disease, liver disease, cancer.
3. Those who have a morbid or irresistible propensity to steal, lie, cheat, drink, blaspheme, set on fire, or abuse the sexual organs.

The third class, or those having irresistible impulsive tendencies are illustrated in such conditions as suicide, homicide, crime and other impulsive or reckless conduct.

In the simplest form, all these vagaries consist of certain ideas which obtrude themselves in varied and divers ways on the consciousness of the individual, and in a limited degree they are present in health; indeed, very few of us escape the presence of doubts, fears and impulses as isolated sudden thoughts, but which are readily restrained or controlled by the dominating power of inhibition. For instance, it is a common experience for persons looking from a height to be tempted to jump down, or in riding on a boat to throw themselves overboard; or when walking in the streets they are suddenly seized with a desire to count the houses or numbers on the doors, or in leaving the office habitually return for fear the safe was left unlocked, or the water running from the faucet, or the doors or windows unfastened. Such doubts, fears and impulses are usually readily restrained; when, however, from any cause they constantly and persistently recur and get beyond control of the will, they eventually dominate the thought, speech and conduct of the individual, thus becoming true psychopathic manifestations of the underlying pathogenic factor which essentially consists in some lesion of the will, and consequent impairment or actual loss of power of self-control. Moreover, there can be little doubt that certain crimes are often due to such morbid ideation which arise in the minds of persons who are not ordinarily regarded as insane, and yet who are wholly unable to resist such pathogenic impulses. Indeed, clinical observation and experience demonstrate the truth that the line of demarcation between "psychosomatasthenia" and insanity is at times as dimly drawn as that which exists between sanity and insanity, or health and disease.

In conclusion, it would seem important, therefore, that in our clinical study of the various psychopathic manifestations of the non-insane psychoneuroses that the essential thing after all is not only to recognize the foundation on which they are based, but also the contributing factors which generate, foster, sustain and develop them into their fullest maturity.

Thus considered, the following deductions would seem warrantable:

1. The psychoneuroses which constitute "psychosomatasthenia" are the forerunners of insanity, and the only difference between them is one of degree.
2. In fundamental nature they are the same, viz., a pathologic lack of inhibitory control of the higher mental directive forces with consequent nutritional cellular instinctive and physical defects, which seriously mar the power of the will, weaken the judgment and intellect, as well as excite or depress the emotional attributes in all degrees of intensity.
3. Their causes are similar, being both congenital and acquired, while heredity, stress, and toxicity are the chief factors of each.
4. Independent of the purely physical clinical phenomena the psychopathic manifestations dominate the syndrome, direct the prognosis, and most acutely solicitate treatment.
5. In their incipiency they are extremely amenable to curability, but when neglected the morbid ideation becomes fixed and persistent, thus defying all therapeutic efforts to give relief.

DISCUSSION.

Dr. H. A. Tomlinson, *St. Peter, Minn.*, declared that Dr. Punton's effort to find some other term than insanity to describe mental perversion reminded him of a letter he once received from the mother of a patient, saying that the patient must be insane, after that it is simply a question of degree. It does not alter the nature of the mental disturbance to use another term, having the same meaning, to describe it. Dr. Tomlinson hopes that the time will come when the profession will frankly admit the fact of insanity and its significance, and that through the profession the public will be educated to recognize the existence of mental perversion as frankly as they do any other diseased condition. The difficulty is largely a social one and depends on the fact that, as the result of superstition and statutory provision, the word insanity suggests a stigma and gives the individual so afflicted a "subhuman" or quasi criminal status. Calling insanity nervous prostration or psycho-asthenia does not alter the condition or its nature, but it does lead to confusion and helps to keep up the medieval superstition with regard to its nature and significance. As a consequence, instead of being dealt with promptly and intelligently, it is hidden and improperly treated until it becomes chronic and is only recognized when the individual becomes a menace to himself or to the public.

Dr. Smith Ely Jelliffe, New York, said that he could not assent entirely to Dr. Tomlinson's point of view. He was reminded, while listening to Dr. Punton's paper, of his trip throughout Montana. The present study of the psychoneuroses has its analogies to the numerous prospectors' holes scattered throughout the state. Occasionally a deep shaft is found where a Brissaud, Charcot, Janet, Forel, or a Vogt has mined for useful truths, but the surface of pathologic psychology has barely been scratched. It is still in the prospecting stage. He thought it premature, therefore, to assume too much definite knowledge concerning the subject under discussion. He quoted Professor Cattell's remark that a 4-year-old child could exhibit more psychologic activities in an hour than a historian could record and analyze in a lifetime. It is folly, he said, to argue concerning words. It is natural that the needs of language are such that new words are inevitable, but the facts for which the words stand are antecedent, and a prevalent fault of all is to ascribe too much of an entity to word symbols, forgetting that they are purely abstract representations. Insanity is not an entity; it has no relation to an entity. Psychoneuroses as a word means nothing. Insane patients have series of symptoms. These symptoms are capable of description, of analysis, of synthesis, etc., and individual cases may be grouped, and generalized ideas made therefrom, but the abstraction should be clearly separated from the realities, especially in speech. It is imperative, Dr. Jelliffe believes, to discard the old metaphysical categories of the mental faculties. They are not separate nor separated by dividing walls—will, emotions, memory, are not separate in the mind. The entire mental life is continuous. There may be some anatomic groupings of elements that render Wernicke's ideas concerning pathologic psychology comparatively sound, but the old terminology of metaphysical psychology still encrusts and encumbers the psychiatry of today to the discomfort of students. Dr. Jelliffe is not in favor of the complex word used by Dr. Punton, as it creates an air of definiteness about conditions which are extremely hazy and which, he thinks, are only beginning to be understood. The simple term, psychoneuroses, including neurasthenia, hysteria and states of mild psychical depression or exaltation, is a better one to use. He agreed with Dr. Punton that the word insanity carries with it a stigma which, if applied to patients who are suffering from the varieties of psychoneuroses mentioned, works a great injustice. To say to the world that a person who has a psychoneurosis is insane, although he may be sufficiently ill mentally to be treated as a pronounced case of mental imbalance, serves no useful object and is often an imprudence which brings about a complete mental breakdown, which the physician should try to avoid.

Dr. H. T. Pershing, Denver, Col., said that when a physician is asked to determine whether a patient is or is not insane he must first ascertain whether the mind is changed by disease or defective by reason of imperfect development. He must then find the degree of defect. There are many mental defects which do not constitute insanity, but if the mind is so imperfectly developed that the individual is unfitted thereby for the ordinary relations of life then he is insane. Dr. Pershing thinks that if neurologists were to keep these two points in mind they would be saved a great deal of trouble, especially in medicolegal cases.

Dr. J. H. McBride, Pasadena, Cal., said that if Dr. Punton intends to be understood as saying that hysteria always precedes insanity he should certainly differ from him. Hysteria may precede insanity, but there are many insane who are never hysterical. Not all emotional display in insanity can be called hysteria. There is certainly a prejudice against the person who is known to have been insane, and it must be admitted that there is some reason for it. In most cases of recovered insanity it is not difficult to see that the insanity has left a scar; there is some loss of mental vigor and balance. Insanity is not a highly recoverable disorder. Out of ten insane patients possibly two or three recover and stay well. There are many cases of insanity in which the disorder is due to causes that might be called incidental, acute infections, traumatisms, etc. In these cases hereditary tendency must play a very subordinate part. In the great majority of cases, however, the insanity is essentially due to conditions of brain structure that are inborn. These people have brains that are made of crumbly material that breaks down under adverse conditions of life, and in these individuals there is a very low rate of recovery. Here the insanity is the final stage in a degenerative tendency that has been in operation for one or more generations. It is inevitable, therefore, that only a minority of cases of insanity should be curable. Nature is attempting to eliminate the unfit and, though she may adopt cruel methods and proceed in a bungling fashion and often fail, yet in the long run the object is accomplished.

The Physician's Holiday.—The reorganization of the medical profession makes it possible for one physician to leave his patients temporarily in the hands of another and fare forth into the world for a period of change and rest.—*Western Medical Review.*

INTESTINAL PERFORATION IN TYPHOID FEVER.

WITH REPORT OF CASES.

WALTER COURTNEY, M.D.
BRAINERD, MINN.

In the general consideration of intestinal perforation in typhoid fever, it may not be amiss to compare it with appendicitis, relative to the surgical history of both. Without going into the earlier history of these pathologic conditions, it will be sufficient to consider them from the time they were prominently brought to the notice of the medical profession. The epoch-making contribution on appendicitis, by Fitz of Boston, appeared in 1886. What ought, equally, to have been the awakening call in regard to typhoid perforation was made by Leyden of Berlin, in 1884, and again in 1886 by Wilson of Philadelphia. What has happened meanwhile? An enthusiastic and glorious achievement for the surgery of appendicitis and only faltering and apathetic efforts in the direction of typhoid perforation; thousands of successful operations annually for the former, and, the world's record in 1904, 362 reported operations on the latter.

Why have we been so intensely active in regard to appendicitis and so hesitant concerning typhoid perforation, when such statisticians as Taylor and Brooks inform us that from 16,000 to 20,000 persons die annually in the United States alone from the latter cause? The answering explanation is not immediately obvious, particularly when we recall that the earlier consideration given to appendicitis was essentially for perforation, abscess and peritonitis. The difference is one of the anomalies of surgical progress.

Of all the explanations that might be advanced, the one that seems most reasonable is the poor results that followed early surgical efforts, in general peritonitis, from whatever cause, and the infrequent and fortuitous contact of the general practitioner with typhoid perforation.

The frequency of perforation in typhoid fever has been variously given by different authorities. Liebermeister found it in 26 of 2,000 cases (1.3 per cent.); Murchison in 48 of 1,580 cases (3.03 per cent.); Curschmann in 22 of 829 cases (2.7 per cent.); Armstrong (Montreal General Hospital) in 34 of 932 cases (3.66 per cent.). In my work it was present in 11 instances in 576 cases (1.9 per cent.).

Curschmann,[1] in his admirable work, says: "I believe that under the most unfavorable circumstances perforation occurs in not more than 3 per cent. of all cases of typhoid fever."

Children, it has been stated, are less liable to perforation than adults. My work offers no assistance on this point, since all the cases were in adults.

As regards sex, there seems to be but little difference, although perforation is said by some writers to occur more often in males. (As my own cases were almost wholly in the male sex, I have no basis for an opinion.)

Season seems to have but little influence. Curschmann states: "The frequency of perforation of the bowel, precisely like that of intestinal hemorrhage, may be extremely variable at different times." This I have particularly noticed in my own cases—the first 3 cases of 11 perforations, occurred in the late months of 1890 and the early months of 1891; the last 3 cases have occurred within the last six months—prior to March 15, 1905.

---

[1] "Typhoid Fever and Typhus Fever," edited by Osler., Nothnagel's Encyclopedia.

That perforation is more likely to occur in cases accompanied by diarrhea would seem to be indicated by the fact that in 30 cases of perforation at Johns Hopkins Hospital, 20 patients had diarrhea, 16 of them at the time of perforation. My 11 cases of perforation showed marked diarrheal tendencies in only 4.

The relationship of tympany to perforation does not seem to be very marked. When there is deep ulceration [illegible] tympany, perforation may be more [illegible] bout by mechanical causes, such as straining at stool, turning in bed, etc. Curschmann is inclined to believe that tympany is not so much a sign of severe intestinal lesions as it is a symptom of severe general infection, which gives rise to paralysis of the muscular layer of the intestine and consequent gaseous distension. My own experience tends strongly to confirm this view.

Hemorrhage in typhoid fever occurs in varying frequency, in anywhere from 4 to 8 per cent., in the larger collection of reported cases. In 829 cases at Johns Hopkins Hospital it occurred in 6 per cent. In my 576 cases it occurred in 43 (7.4 per cent.), counting all evacuations of blood sufficient in amount to be termed hemorrhage; it was the cause of death in 11 cases. The average number of hemorrhages per case was 3.3. The average number of hemorrhages to each patient who died was 5.1. Hemorrhage occurred in 3 of the 11 cases of perforation.

Like perforation, I have found hemorrhage to vary considerably at different times, but with no well-marked relationship between the two. In my hemorrhagic cases the intestinal loss of blood occurred in nearly all during the primary attack of the fever, and seldom during a relapse.

In dealing with the subject of intestinal perforation, Keen[2] summarized the 83 operative cases that had been reported. The result showed 19.36 per cent. of cures and 80.64 per cent. of deaths. The first three operations ever performed for typhoid perforation were by Mikulicz, Kussmaul and Bontecou, in the order named.

Finney[3] gives a brief history of the 112 operative cases he was able to collect. Of these 23 patients recovered (20.05 per cent.).

Harte and Ashurst[4] summarize the 362 operative cases that they collected with the following results: Recovered, 94 patients (25.97 per cent.); died, 268 (mortality, 74.03 per cent.). Their analysis by lustrums gave:

1884-1888, 10 cases, mortality 90 per cent.
1889-1893, 16 cases, mortality 87.5 per cent.
1894-1898, 100 cases, mortality 72 per cent.
1899-1903, 166 cases, mortality 69.2 per cent.

This readily gives an idea of the progress in operative work.

Of my 11 perforation cases, 5 patients were operated on, with one recovery and four deaths—*recovery*, 20 per cent.; mortality, 80 per cent. All the patients not operated on died.

The status of perforations not operated on does not seem to change. Various writers place the mortality in *these cases* at 95 per cent., and this opinion is confirmed by Curschmann.

One can not comprehensively discuss the subject of intestinal perforation of typhoid apart from typhoid fever itself. A long list of cases from any institution, or practitioner's records, when carefully studied, can scarcely fail to be of value. The accurate and painstaking work on typhoid fever, performed under Osler, at Johns Hopkins Hospital, throughout a number of years, has been of incalculable benefit in the study of every feature of the disease. Similar work elsewhere, of course, is entitled to its proper share of credit.

Simply to review cases of perforation, I believe, would not be of the same value as if all typhoid cases were given, even brief, consideration. This report is intended to cover a period of fifteen years, from March 15, 1890, to March 15, 1905. The work was all performed within the Northern Pacific Railway Hospital, at Brainerd, and does not include cases among our employes and others treated at their homes. There is a peculiarity about the work that does not often exist outside of railway hospitals, and that is the extent of territory which the work covers. The patients came from along the railway lines in Minnesota, Northern Wisconsin, Manitoba, North Dakota, and as far west as the middle of Montana.

In view of the fact that more than 90 per cent. of the patients came from abroad, frequently with little or no previous observation or treatment, often in the second week of the disease, sometimes in the third, with mental hebetude, and occasionally delirium, already established, it will be appreciated how difficult it is to be exact concerning early clinical features in many of these cases.

During the fifteen years (1890-1905) we admitted and treated 576 patients with typhoid fever. Of these 534 *recovered* (92.7 *per cent.*), and 42 died (a mortality rate of 7.3 per cent.). The causes of death were as follows: Toxemia, with severe nervous manifestations, 12 (28.5 per cent. of the total mortality); hemorrhage, 11 (25.9 per cent. of the total mortality); intestinal perforation, 10 (28.8 per cent. of the total mortality); pulmonary complications, 5 (11.9 per cent. of the total *mortality*); acute heart failure, with sudden death, 4 (9.5 per cent. of the total mortality).

Exactly 75 per cent. of the 576 patients were admitted during the last six months of the year, from July 1 to December 31; the remaining 25 per cent. were admitted from January 1 to June 30, while over one-third (35.76 per cent.) of the total cases were admitted during the months of September and October.

In this series of 576 cases, 291 patients, over 50 per cent., were admitted and treated during the last five years, during which time there was a total of 16 deaths, from all causes, or a mortality rate of 5.5 per cent.

The total mortality rate in 829 cases of typhoid fever treated at Johns Hopkins Hospital during the years 1889-1899 was 7.5 per cent. Comparison tends to show that typhoid fever patients' chances for recovery are not necessarily minimized by being transported long distances on railway trains.

In the hospital we used Widal's method of serum diagnosis in a considerable proportion of the cases, particularly the doubtful ones. I wish incidentally to call attention to an objective symptom of typhoid fever, namely, tremor *of the tongue*. I have found it almost universally in all grades of cases, and from the earliest stage to convalescence. In character it may vary from complete loss of muscular control to a mere vibrating tremor movement, noticeable only near the tip. Associated with other of the usual clinical symptoms I have found it of value before Widal's reaction test could be elicited.

4	28	Severe, with mental apathy and delirium.	Slight diarrhea.	None......	Yes....	17th....	With marked typhoid state; abdomen distended and involuntary bowel movement of small watery stools.	Distention of abdomen; irregular breathing; subjective symptoms concealed.	No, comatose..	No..	No..	Yes, before onset of perforation.	Yes...
5	25	Mild...	No diarrhea.	From bowels 7 days before perforation; temp. fell 3 degrees.	Not marked.	30th....	During bowel movement sudden severe diffuse pain in abdomen.	Severe cramp-like pain lasting only a few minutes.	Yes, very severe: diffuse at first; later localized in right iliac fossa.	No..	No..	Yes....	No....
6	37	Mild, early conval., relapse, complicated with phlebitis.	No diarrhea.	None......	Yes....	31st; 8th day of relapse.	Sudden severe abdominal pain; patient cried out in agony; face and extremities cold and clammy; pain in genitals.	Severe pain in abdomen.	Yes, diffuse; referred also to penis and scrotum.	No..	Yes..	Yes....	Yes...
7	24	Severe....	No diarrhea.	One on day of perforation.	Not marked.	19th....	Gradually increasing distension and tenderness; hemorrhage from bowels	Rigid abdomen, tender on pressure; rapid pulse.	None.....	No..	No..	Yes, late..	No....
8	20	Severe. Marked mental apathy.	No diarrhea.	Yes, 5 on different days preceding perforat'n.	Yes, marked.	48th....	Sudden	Severe pain near McBurney's point; chill.	Yes, severe in right iliac fossa.	Yes..	No..	Yes, late...	No....
9	30	Severe; high temp. and delirium.	No diarrhea.	None......	None, until late in disease.	17th....	Sudden; severe abdominal pain; lips pallid; very restless; skin cold and clammy.	Paroxysmal pains in abdomen.	Yes, severe in right iliac fossa.	No..	Yes, on extremities.	No....	Yes, very marked.
10	24	Mild, rapid conval., relapse severe.	No diarrhea.	None......	Not marked.	52nd, 10th day of relapse.	Sudden; severe colicky pain; lips pallid; face drawn and expression anxious.	Severe paroxysmal pain; most marked in right iliac fossa.	Yes, severe and diffuse at first; later localized on right side.	No..	Yes, slightly.	No....	No....
11	43	Mild; mental condition rather dull.	No diarrhea.	None......	Yes, marked.	15th....	Sudden; severe pain in abdomen with signs of collapse.	Severe abdominal pain; chill.	Yes, diffuse at first; later more on right side.	Yes..	Profuse cold sweat.	No....	Yes...

As regards the general treatment of the cases, I would say that in this hospital for more than sixteen years we have relied mainly on the tub bath.

The detailed histories and a table of our perforation cases will be given after the treatment.

PATHOLOGY OF INTESTINAL ULCERATION AND PERFORATION.

The lesions of the intestine in typhoid fever consist mainly of changes in the lymphoid tissue and these may be divided into four stages: First, the stage of hyperemia; second, that of medullary infiltration; third, that of necrotic destruction and ulceration, and, fourth, that of cicatrization. "In general these anatomic stages correspond with the clinical course of the disease. It is to be borne in mind that the intestinal lesion does not develop and extend simultaneously and uniformly, but rather in stages, often distributed over a considerable period of time, and it likewise undergoes involution in a corresponding manner" (Curschmann). This, in a measure, will account for the appearance of perforation at varying times in a long list of perforation cases. For a more extended description of the minute anatomic changes of typhoid fever, such authorities as Curschmann, Osler, Mallory and others may be referred to.

The so-called medullary infiltration and consequent coagulation necrosis may only extend to the muscular coat, which would form the base of the ulcer. This is most frequently the case. Or the ulcerative destruction

Rose to 103 then fell to 102.	Rose from 98 to 112.	Not noted. .	Extremely tender in right iliac region.	Not mentioned.	No count	Yes	6	Death in 12 hours.	*Partial autopsy. .*	Not reported	Two in ileum 15 and 21 in. above cecum.
Rose to 104.6 then fell to 100.	Rose from 98 to 124.	Rapid violent hiccough.	Noticeable tenderness in right iliac area.	Not mentioned.	No count	No	. .	Death in 55 hours.	No autopsy.	. . . .	. . . .
By axilla; rose 101-104; later fell to 103.2.	Rose from 120 to 144.	Rose from 24 to 44.	Distended. . .	Abolished.	No count	No	. .	Death in about 56 hours.	*Partial autopsy* showed typical typhoid ulcers; intestines matted together with many adhesions. (One perfora'n found in ileum 12 in. from cecum.	Very adherent and inflamed.	One in ileum 12 in. above cecum junction.
Fell at first to 99.8; then rose 102.2.	Rose from 84 to 106.	Very rapid and shallow; hiccough.	Distended and extremy tender.	Obliterated.	No count	Yes	19	Death in 75 hours after perforation & 56 hrs. after operation.	Partial autopsy; bowels covered with *deposit* of lymph; perforation closed and stitches holding; appendix adherent.	Much inflamed and adherent; not removed at operation. (Patient in bad shape)	One was located in ileum 6 *in. from* colon. Wound admitted end of finger; *only one* perforation found; free fecal matter in cavity at operation.
High at first 104; fell quite rapidly to 95.6 before death.	Rose from 106 to 122; very weak.	Shallow and very rapid.	Distended; very rigid.	Obliterated.	No count	No	. .	Death in 25 hours.	Partial autopsy; abd. cavity contained free fecal *matter* and a large amount of turbid fluid; many ulcers with softened bases; one perforating; clot in femoral vein.	Thickened and adherent.	One found at autopsy; located 18 in. *from* ileocecal valve, large size.
No change . .	Rose from 100 to 150.	Rapid. . . .	Board-like; very tender.	Obliterated.	7,894 immed'tly after onset of sympts.	No	. .	Death in 30 hours.	*No autopsy.*	. . . .	. . . .
Rose, then fell; after operation fell to 97, then rose to 105.	Rose slightly before operation; markedly after, to 150.	No change . .	Partly distended; hard.	No marked change.	12,223 made just after onset of sympts.	Yes	2	Death in 10 days and 4 hrs. after perforation.	Complete autopsy; negative except in abdomen; purulent exudate; catgut suture given way with opening into bowel free. No attempt at repair.	Very adherent, much thickened; removed at operation.	One very small one found 2 in. from ileocecal valve.
Fell from 102 to 98 4.	*Almost imperceptible*: rose from 90 to 134.	Rapid and shallow; rose to 0.	Very rigid and tender.	Nearly *obliterated.*	No count	No	. .	Death in 55 minutes after perforation (approximately).	No autopsy.	. . . .	. . . .
No marked change.	Rose after operation from 84 to 116; no change before.	Rapid and shallow; thoracic.	Very rigid; moderately distended.	Not obliterated.	No count after perforation.	Yes	2¼	Recovery. .	. . . .	Very much inflamed; removed at operation.	Two small pin-point perforations found in ileum close to colon. 1 other large one (⅛ in. in diam.) 12 *in. from colon.*
No change before operation; after operation it rose to 101.4 then fell to 97; then vacillated.	No change before operation; after operation it varied between 130 & 148; was between 82 and 90 before perforation,	Rose in frequency; very shallow.	Moderately distended; very rigid; painful on pressure.	Partial obliteration.	No count	Yes	3¼	Death *in* 75 hrs. after perforation and 71½ hrs. after operation.	No autopsy.	Much congested and inflamed; removed at operation.	Two perforations found in ileum within 8 in. of colon; and one pin-hole perforation 15 in. above cecum closed by plastic lymph and adherent omentum and surrounded by o'd peritonitis. Free pus in peritoneal cavity.

may include the muscular layer and subserous tissue and leave only the peritoneal coat, through which infection may pass and cause a local peritonitis. Again, it may involve the whole thickness of the intestinal wall, and when the slough separates a complete perforation results, varying in size from a pin hole to an opening including a third or more of the circumference of the bowel. The escape of intestinal contents and infective germs may vary from a minute quantity to a sufficient amount to flood a great portion of the peritoneal cavity, depending usually on the size of the perforating ulcer. When the amount of leakage is great, general peritonitis is almost certain to appear in a very short time. When the opening is extremely small and the leakage slight, there may be only a localized peritonitis. In Case 11 of this series it was disclosed at operation that there had been an early pin-hole perforation with localized peritonitis to the extent of eroding the bowel of its glossy appearance throughout the affected area, and later two large ulcers in other locations had perforated, causing the symptoms which called for operation. The primary perforation had been closed by plastic matter and the adhesion of the neighboring omentum.

In certain cases in which the peritonitis is limited and limiting adhesions and walling off has occurred, abscesses may appear and require to be dealt with weeks and may be months afterward.

In form the perforation may be large and irregular, large and circular, small and cribriform, or it may be slit-like or oblong. The large circular ulcers are thought to be due to sloughing, the cribriform to ulceration, and the slit-like to mechanical traumatism. They are usually opposite the mesenteric attachment, though rarely they may open between the folds of the mesentery and cause a retroperitoneal abscess.

The perforation, as a rule, is single. In the five patients operated on, however, it was single in only two; in two of the cases there were two perforations, and in one three.

The site of perforations is usually found in the lower end of the ileum within from 12 to 18 inches of the cecum. Infrequently it may occur at any point along the digestive tract. It is not infrequently seen in the cecal region of the colon, including the appendix. Typhoid ulceration (rarely with perforation) may be found widely scattered along the digestive tract. A number of well-authenticated cases of typhoid ulceration of the esophagus and consequent stricture have been reported. Mitchell[5] reports eight cases. I have seen two cases of esophageal stricture following well-authenticated typhoid fever. In neither case could the stricture be charged to traumatism occurring in the course of the disease. In both cases it supervened before convalescence was established. The first case was in a young girl of 20, seen in consultation with Dr. F. J. Campbell of Fargo, N. D., about ten years ago. The stricture was located about the junction of the middle and upper thirds of the esophagus. Soon afterward the patient developed an empyema which so reduced her strength that she could not undergo an operation for the stricture, which still persisted, and she died a few weeks later. The second case, also in a young girl of about 20, was seen in consultation with Dr. John H. Dunn, of St. Cloud, about three years ago. The stricture was located at the junction of the middle and lower thirds. Later it was found necessary to do a gastrostomy to assist in overcoming the stricture. The patient, I am informed, made an excellent recovery.

SYMPTOMS.

Perforation in typhoid fever rarely occurs during the first week of the disease; the majority of cases are seen during the second and third weeks; it may occur, however, at any time during the latter part of the disease and convalescence. It is not infrequently seen during a relapse. The so-called preperforative symptoms are usually too vague and indefinite to be of much practical value to the average practitioner doing his work outside of hospitals.

Pain.—The earliest reliable symptom of perforation is pain, which usually is complained of in the cecal region; it may be referred, however, to the epigastric or pelvic regions. Occasionally pain is complained of in the genitals. The character of the pain may vary from a severe stabbing nature to more or less of a dull ache. Often its severity will cause the patient to cry out from his suffering. Patients who are irrational may fail to complain of pain. Occasionally with pin-hole perforations and limited peritonitis there may be no complaint of pain (Case 11).

Rigidity.—The next most important symptom is rigidity of the abdominal muscles, following quickly after the appearance of pain. This rigidity may be confined to the right internal and external obliques and the recti muscles, or the whole abdomen may be rigid.

Tenderness.—This is the next symptom of marked importance and is usually found in the cecal region, though it may also be adduced by pressure toward the epigastric or pelvic regions. All other symptoms are of varying importance.

Vomiting.—This is a symptom which may occur coincidentally with, or soon after, the appearance of pain. In some cases of typhoid fever, however, vomiting is a symptom that appears early and frequently throughout the acute stage of the disease. In such a case its value as a symptom of perforation would not be of marked importance.

Temperature.—In quite a number of cases of perforation there is often a remarkable drop of temperature, sometimes to near the normal point; with the advent of peritonitis the temperature again rises.

Pulse and Circulation.—The shock of perforation and peritonitis usually lowers the force of the pulse, while the rate is greatly increased, often from the usual rate of 90 to the unusual one of 130 or more. The skin of the face and hands may appear pallid and even somewhat cyanosed, and is frequently covered with profuse perspiration.

Respiration.—The respiration may be somewhat quickened, but is not likely to become costal in character until peritonitis is established.

Facial Expression.—In perforation the expression of the face is often marked by anxiety, suffering and general distress to an extent which might be called characteristic, almost Hippocratic in type.

Liver and Movable Dullness.—Liver dullness must have been carefully noted, from time to time, prior to perforation, to be a symptom of important value. Preexisting tympany may have reduced the area of liver dullness almost to the vanishing point before the admission of free gas into the peritoneal cavity. Movable dullness in the flanks is not likely to be present until peritonitis with effusion has appeared; hence it could only be a symptom of late value.

Blood.—Leucocytosis may be mentioned as a symptom of possible value. To be of practical utility, however, a leucocyte count would necessarily have to be made hourly as it (leucocytosis) would not appear until peritonitis had supervened, and to wait for this might be a waste of valuable time.

Summary of Symptoms.—Given a case of typhoid fever with clinical symptoms, pathognomonic of the disease, backed up by Widal's serodiagnosis, if possible, and presenting, after the first week, the three cardinal symptoms, pain, rigidity and tenderness in the cecal region, supplemented by some of the less valuable symptoms, and it will not only be expedient, but reasonable to diagnose intestinal perforation.

Osler's schema[1] for the observation of perforation symptoms should always be at hand for the observance of internes and nurses.

DIFFERENTIAL DIAGNOSIS.

It may be necessary frequently to differentiate between intestinal perforation of typhoid fever and acute appendicitis, with or without perforation; from intestinal hemorrhage of typhoid; from typhoidal peritonitis without perforation; from peritonitis due to tubal disease; from gangrene or perforation of the gall bladder; from perforating gastric and duodenal ulcers; and from suppurating mesenteric glands.

Time will not permit me to consider the symptoms, conditions and features that might be adduced in differentiating each of the above. Cumston,[6] of Boston, in an extended review, terminates his article by saying: "In closing, I think I can sum up in a word all that has been said in this paper, namely, that every time an appendicitis exists, either alone or associated with typhoid fever, an operation is indicated." I believe the same conclusion, namely, operation, would hold good for all the other conditions, with the possible exception of intestinal hemorrhage, and even this has been surgically treated with reported success.

---

[5] Johns Hopkins Hosp. Rep., vol. viii.

PROGNOSIS.

The prognosis in intestinal perforation of typhoid, without operation, is almost hopeless. The chances for recovery do not exceed 5 per cent., under the most sanguine expectations. With operation, the prognosis will depend, in a large measure, on early surgical interference, the extent of the peritonitis, the physical condition of the patient, and the absence of secondary perforation and intestinal hemorrhage. Some writers claim that there should be 50 per cent. of recoveries if the operation is undertaken within the first three hours. With the marked improvements in the treatment of peritonitis, these hopes would not seem to be too sanguine. At Johns Hopkins Hospital 30 per cent. of recoveries were obtained from all operations. In my fatal operative cases, one patient who was operated on 19 hours after symptoms of perforation lived for 55 hours and succumbed to general peritonitis; another lived ten days.

TREATMENT.

All patients with typhoid fever who have suffered intestinal perforation, immediately on diagnosis, should be treated by laparotomy, and the only deterrent to operation should be a moribund condition of the patient. Wilson has well said: "The courage to perform it (operation) will come of the knowledge that the only alternative is the patient's death."

Anesthetic.—I have used local anesthesia, from cocain, and general anesthesia, with ether, and my preference is decidedly for the latter.

The Incision.—The incision that I have found the most useful and satisfactory is the one made through the right rectus muscle and opposite the cecal region. After gaining entrance to the peritoneal cavity the appendix and cecum—even the ascending colon—should be thoroughly examined; next, the lower portion of the ileum, beginning at the cecum. When the perforation is found, it is best to close it with a suture of linen or silk; if small, it can be readily closed with a purse-string suture; if large, Lembert's, Halstead's mattress, or Cushing's right-angled sutures may be used; in some instances, it will be well to strengthen with a second tier. There is a difference of opinion among writers as to whether the opening should be closed in the longitudinal or transverse direction of the bowel. Probably this is a matter of no particular moment, unless the opening is so large that the necessary suturing may diminish the lumen of the bowel to dangerously narrow proportions, in which case the question of resection may have to be considered. If there are other ulcers presenting a perforating appearance, it would be wise to place reinforcing sutures to prevent future accidents.

If the appendix is inflamed, as it frequently is, it should be removed, even though perforation is not present. In the last three cases it was found decidedly inflamed and in each instance it was removed.

The toilet of the peritoneum is important and probably would be the next step in the progress of the operation. If there has been a considerable escape of fecal matter, irrigation with normal salt solution would be of value. If fecal matter is not present (and the peritonitis is confined to the region of perforation) or has gravitated to the pelvis, the effusion fluid may be withdrawn by a suction syringe or removed by careful sponging. Tubular drainage should be introduced to the bottom of the pelvis, probably through a stab wound on the left, as well as through the operation wound on the right. This should be supplemented with the necessary amount of Penrose and gauze drainage. At this time the sutured portion of the bowel should be brought opposite the operation wound and maintained there by gauze or by a few stitches of ten-day catgut. This position of the bowel will be of decided advantage in case the suturing should yield and leakage result. Such portion of the wound unoccupied by drainage may be closed with through-and-through sutures. After the application of a voluminous dressing and the return of the patient to bed, he should at once, or as quickly as possible, be placed in Fowler's position to allow gravitation of effusion fluid into the pelvis, where the drainage has been placed. The after-treatment will consist of the necessary surgical attention and such general typhoid treatment as may be applicable.

If positive symptoms of postoperative perforation occur, one should not hesitate, if the patient's condition will permit, to reopen the wound or to perform a new laparotomy and deal with the conditions found. Cushing[7] reports a case with recovery in a boy of 9 years, in whom laparotomy was performed three different times: First, for perforation; second, for supposed perforation, and, third, for acute intestinal obstruction, when a new perforation was also found.

I am greatly indebted to Dr. W. H. Buskirk for his valuable and painstaking assistance in the examination and selection of data from our hospital and clinical records for the purposes of this article.

Case 1.—Male, aged 26, was admitted to the hospital July 29, 1890; diagnosis typhoid fever. Temperature, 102.8; pulse, 80. No history is recorded of condition prior to admission. The course of the disease was moderately severe throughout, temperature running from 101.2 to 102 in the morning and from 103 to 104.8 in the evening; pulse averaging 85 and never going above 98. There was some diarrhea. The patient perspired freely at times.

August 9: At 7:15 a. m. temperature was 102.2; pulse, 92. Patient was suffering severe pain in abdomen. At 10 p. m. temperature was 101; pulse, 104. There was persistent vomiting of dark green material, with undigested milk.

August 10: At 7 a. m. temperature was 97.2; pulse, 100; patient still in great pain. At 4 p. m. temperature was 104; pulse, 130; patient covered with cold sweat. At 6:30 p. m. temperature was 101.4; pulse, 140; still in cold sweat.

August 11: Patient gradually sank and died at 8:45 p. m. Perforation occurred on the fourteenth day after admission, and death in from 48 to 50 hours after perforation. No autopsy.

Case 2.—Male, aged 30, was admitted to hospital Feb. 4, 1891, having been sick one week; diagnosis typhoid fever. He had a moderate run of fever, with temperature running from 100.8 to 103.2, pulse averaging about 90. There was no diarrhea or hemorrhage; his general condition was good.

March 4: At 8 a. m. there was some pain in the abdomen; two hemorrhages occurred from the nose; there was vomiting during the late afternoon. Temperature was 100 in morning, rising to 103 at 1 p. m. and dropping to 102 at 4 p. m. Pulse was 98 at 8 a. m., 100 at 1 p. m., and 112 at 4 p. m. The symptoms grew rapidly worse and perforation was diagnosed. At 9 p. m. laparotomy was performed; median incision was made. Fecal matter was found scattered throughout the peritoneal cavity. A perforation, irregular in shape and nearly three-quarters of an inch in diameter, was found in the ileum about 15 inches from the cecum; an attempt at suturing followed, but was unsuccessful because of the friable and softened condition of the intestinal walls. Patient being in collapse, only drainage was inserted in wound.

---

[6] "The Clinical Aspect and Differential Diagnosis of Appendicitis and Typhoid Fever," Amer. Jour. of the Med. Sciences, May, 1905.

[7] Johns Hopkins Hosp. Rep., vol. viii.

He was returned to bed. His condition grew steadily worse and he died at 4 a. m. March 5, 12 hours (estimated) after perforation; on the sixteenth day of the disease. Partial autopsy revealed general peritonitis and a second perforation of the bowel 6 inches above the one found at operation.

Case 3.—Male, aged 43, was admitted to hospital Oct. 17, 1891. He had been sick 10 days; diagnosis, typhoid fever. His condition was not bad; temperature varied from 101 to 102, and pulse from 80 to 92 on day of admission.

October 18: At 2:15 a. m. he had a chill; temperature, 103.2. At 3 a. m. there was severe pain in the abdomen, continuing during day. At 4 a. m. temperature was 104.6, and pulse 98. At 8 p. m. temperature was 104, and pulse 106.

October 19: At 4 a. m. temperature was 102.4, and pulse 104. At 8 p. m. temperature was 100, and pulse 112. The patient was feeble; he vomited several times during the day and sweated profusely; he had violent hiccough. The pain continued severe during day.

October 20: His condition grew worse during the early part of the night. At 4 p. m. temperature was 100.2, and pulse 124, and was growing more feeble and rapid. At 9:30 a. m. there was vomiting. At 9:38 a. m. death occurred. Perforation occurred on the eleventh day of the disease; death, 55 hours later. There was no operation. No autopsy.

Case 4.—Male, aged 28, was admitted to the hospital Aug. 23, 1896. He had been sick seven days; diagnosis, typhoid fever. He had a severe run of fever, with temperature from 102 in the morning to 104.8 and 105 in the evening. Pulse from 106 to 126. There was slight diarrhea, some vomiting, and mental apathy with some delirium.

September 2: Patient had been in marked typhoid state and delirious; the abdomen was distended. At 7:30 p. m. respiration was very irregular, and there were involuntary bowel movements. Temperature was 101.2; pulse, 120, and respiration 24. At midnight the axillary temperature was 104; pulse, 132, and respiration, 32.

September 3: Temperature varied from 103 at 4 a. m. to 104 at 4 p. m., pulse ranged from 120 to 130, and respiration from 26 to 30. The patient was delirious, and the abdomen was distended.

September 4: At 4 a. m. the temperature was 102, pulse 120, and respiration 34. At 4 p. m. temperature was 103.2, pulse 144, and respiration 44. Symptoms of previous day were more marked.

September 5: All symptoms were increased in severity, and the patient died at 3:35 a. m. There was no operation. A partial autopsy showed abdominal ulcers, one of which had perforated. There was also considerable peritonitis.

Case 5.—Male, aged 25, was admitted to hospital Oct. 14, 1897. He had been sick two weeks; diagnosis, typhoid fever. The fever ran a light course, the temperature averaging 103.6 in the evening and pulse not over 80.

October 23: There was hemorrhage from the bowel, but no symptoms of collapse; temperature fell from 101.8 to 98.8, and pulse from 76 to 60. The patient did well for several days after the hemorrhage, temperature and pulse running as before.

October 30: At 5:30 p. m. there was a sharp pain in the abdomen during passage of stool; respiration increased; face became pinched in appearance. The patient lay in bed with his knees drawn up. The temperature fell at first and then rose. Perforation was thought of, but the surgeon was not warned until next morning.

October 31: Operation was performed at 11 a. m., 19 hours after first symptoms of perforation. A median incision was made below the umbilicus. On opening the abdomen a large amount of gas and fecal matter escaped through the wound. The intestine was covered with lymph deposit, and there were numerous adhesions. In the ileum, about 6 inches from the colon, a large perforation was found, which would admit the end of the fingers; the edges were well defined. Other unperforated ulcers were apparent through the bowel wall. The peritoneal cavity was sponged dry and flushed with normal salt solution; tubal drainage was inserted and the wound partly closed.

November 1: The condition became critical, and there was some vomiting. At 4 a. m. the temperature was 101, pulse 134. At 4 p. m. temperature was 101, pulse 130 and weak.

November 2: At 4 a. m. the temperature was 101, and pulse 144. At 4 p. m. temperature was 104.2, and pulse 160. The patient grew rapidly worse and died at 8:30 p. m.

Autopsy showed very severe general peritonitis, with extensive adhesions. Suturing in the bowel was intact. Perforation occurred on the thirtieth day of the disease; death occurred 75 hours after perforation and 56 hours after operation.

Case 6.—Male, aged 37, was admitted to hospital Oct. 22, 1898. He had been sick ten days; diagnosis, typhoid fever. At the time of admission there was tympanites and some vomiting; rose spots were also present. The case ran a light course after admission to hospital until convalescence began. The man had a relapse, beginning November 4, but it was not severe. On November 9 he developed a phlebitis.

November 12: During the day the temperature ran high and the pulse increased. At 4 a. m. the temperature was 103.6 and pulse 106. At 4 p. m. the temperature was 104, pulse 108. At 9:30 p. m. there was sudden acute abdominal pain; the patient cried out in agony; the abdomen became rigid; extremities and face were cold and clammy; pulse was rapid, feeble and fluttering. Pain was referred to genitals.

November 13: At 4 a. m. the temperature was 102 and pulse 122. At 4 p. m. temperature was 97, pulse 122. There was severe pain throughout the day, with vomiting, delirium and cold sweat. Temperature was subnormal all day, running as low as 95.6. The condition grew worse, and the patient died at 10:30 p. m.

No operation was performed, because of the severe phlebitis and the low condition of the patient. Autopsy showed perforation of ileum 18 inches from the ileocecal valve, with free fecal matter and turbid fluid in the abdominal cavity. There were numerous ulcers with softened bases, one black and almost perforated, and a clot in the femoral vein extending into the pelvis.

Case 7.—Male, aged 24, was admitted to the hospital Sept. 23, 1902. He had been sick two weeks; diagnosis, typhoid fever. Rose spots were present on admission. The case ran a severe course after admission, temperature running from 102.6, with pulse 96, in the morning to temperature of 105 and pulse 116 in the evening.

September 29: At 7 a. m. temperature was 102 and pulse 100. At 8 p. m. temperature was 103.2 and pulse 120. The condition of the patient was the same as on former days until 8 p. m., when there was hemorrhage from bowels.

September 30: At 4 a. m. the temperature was 101 and pulse 100. At 3 p. m. temperature was 101 and pulse 144. Blood count showed 7,894 leucocytes. The condition was serious; pulse was rapid and weak. He did not complain of pain; abdomen was rather rigid and somewhat tender on pressure; liver dullness was diminished.

October 1: At 8 a. m. the axillary temperature was 98 and pulse 120. At 8 p. m. the axillary temperature was 101.4 and pulse 150. He vomited during the day. Death occurred at 11:30 p. m. Perforation occurred on the nineteenth day of the disease. No operation (no reason given in clinical history). Death occurred in about 30 hours after perforation. No autopsy.

Case 8.—Male, aged 20, was admitted to the hospital Jan. 23, 1903. He had been sick one week with prodromal symptoms of typhoid; diagnosis, typhoid fever. The general condition on admission was rather bad; the abdomen was distended and there was pronounced typhoid mental condition. At 7 a. m. the temperature was 103 and pulse 72. At 8 p. m. the temperature was 104 and pulse 94. The patient had two hemorrhages on January 24, one on January 25, another on

January 26; also a slight chill, and another hemorrhage on January 27. During this time the temperature continued high, and pulse ran from 78 to 84. There was no diarrhea.

January 31: The general condition was about the same. At 8:30 p. m. he was taken with sudden severe pain in the abdomen in the right iliac region. He had a chill at 9 p. m. The abdomen became distended and there was general abdominal tenderness more marked at McBurney's point. The pulse was rapid and weak, and the facial expression anxious and drawn. At 10:30 p. m. (diagnosis of perforation having been made) operation was performed under cocain until bowels were exposed; then ether was given. The incision was made through the right rectus. The bowels were much distended, and there were numerous adhesions around the appendix, which was somewhat thickened and congested. The appendix was ligated and the stump turned in by means of formalized catgut suture. A small pinhole perforation was found in the colon within one inch of the appendix; it was closed with Lembert sutures of silk. An ulcer, with gangrenous look and threatening perforation, was found 4 inches from the ileocecal valve; it was reinforced with suture of silk. There were no signs of peritonitis and no increased amount of fluid in the peritoneal cavity. Only local drainage was used, and the wound was closed up to drain. For several days after operation the patient's condition was quite good.

February 3: At 4 a. m. the axillary temperature was 98.8 and pulse 80. At 8 p. m. the axillary temperature was 98.6 and pulse 92. Some distension was present and there was considerable vomiting on this day.

February 7: The patient's condition was serious. At 4 a. m. the temperature was 100.8 and pulse 120. At 8 p. m. the axillary temperature was 104.6 and pulse 128 and weak. The abdomen was distended and tender; there was no infection of the abdominal wound.

February 8: Condition was still serious. Temperature and pulse were about the same as day before. He had blood in stools twice on this day; there was not much reaction of temperature and pulse. At 4 a. m. temperature was 103.8 and pulse 130. At 8 p. m. temperature was 104 and pulse 130.

February 9: Patient's condition was much worse, temperature being uniformly high and pulse rapid and weak.

February 10: Temperature reached 105 and axillary pulse 150. Patient died at 12:20 a. m. February 11.

Complete autopsy: Examination was negative, except in the abdomen. The bowels were found covered with purulent exudate, but not distended; the catgut suture which had closed the stump of the appendix had been absorbed, and, as there were no attempts at repair, the stump was open. The perforation and ulcer, which had been reinforced with silk sutures, had held firmly. The peritoneal exudate was much more marked in the right iliac fossa than elsewhere. There were no fresh perforations. Perforation occurred on the forty-eighth day of the disease and death in ten days and four hours after operation. A mistake was made in this case in using catgut instead of silk for closing the appendiceal stump, and later in not reopening the wound for exploration.

Case 9.—Male, aged 30, was admitted to the hospital Oct. 28, 1904. He had been sick ten days; diagnosis, typhoid fever. He had nose bleed, headache and other characteristic symptoms of the disease, which ran a severe course, the temperature ranging from 102, with a pulse of 96 in the morning to 104, with pulse of 104, in the evening. There was slight vomiting, with some delirium. There was no tympanites until November 1.

November 24: Axillary temperature was 98.4 and pulse 132 at 7 a. m.; respirations, 40. Patient was sweating. At 8:45 a. m. there was sudden severe abdominal pain, occurring in paroxysms; the expression was anxious. The patient was very restless; his lips were pallid; his extremities cold and covered with cold sweat. The abdomen was rigid and extremely tender, the tenderness being most marked in the right iliac fossa. The pulse was rapid, thready and almost imperceptible. At 9:40 a. m. death occurred.

Perforation occurred on the seventeenth day of the disease; death after perforation (estimated) in 55 minutes. No operation. No autopsy.

Case 10.—Male, aged 24, was admitted to hospital Dec. 6, 1904. He was admitted primarily for injury, but complained of having been sick for two or three days. He developed a light run of typhoid; rose spots were present; temperature ran from 100 to 102 and pulse was practically normal; he complained early in the disease of some pain in the right fossa. Blood count, December 9, leucocytes were 10,186, and on December 15, 11,457. He had a typical convalescence, beginning December 24. Temperature was normal all day December 25. Diet was gradually extended. The patient was up and about.

January 17: He had a well-marked relapse, with all symptoms much more severe than during previous illness.

January 19: Temperature was 100.8, with pulse 104 in the morning. Temperature was 100.8, with pulse 110, in the evening. The condition was about the same on January 25.

January 26: Respirations ranged from 20 to 24 and were shallow; there was no delirium, no chills, no diarrhea. This condition continued without change until January 27.

January 27: At 7:30 a. m. the patient was taken with severe abdominal pain, paroxysmal in type and of a colicky nature. His face was drawn and his expression anxious; the lips were slightly pallid; the abdomen was board-like, and there was general diffuse tenderness, most marked in the right iliac fossa. Liver dullness was not obliterated. Perforation was diagnosed, and at 10:15 the patient was taken to the operating room.

Operation.—A lateral incision was made through the right rectus. The appendix was very much inflamed and was removed; the stump was closed with a purse-string suture of silk. The appendix was not gangrenous or perforated. The ileum was examined; two small pin-point perforations were found close to the cecum and were closed with purse-string sutures of silk. Two ulcers were found near the same area with their bases much inflamed; they were reinforced with continuous sutures of silk. About 12 inches from the colon a large perforation was found with well-marked borders and a punched out appearance; it was one-eighth of an inch in diameter. It was turned in with purse-string suture of silk. General peritonitis present; the abdominal cavity was filled with a seropurulent fluid. A tube and three Penrose drains were inserted to the bottom of the pelvis. The upper angle of the wound was closed with three interrupted sutures of silkworm gut. The patient stood the anesthetic well and was placed in bed in Fowler's position. During the evening he received a hypodermoclysis of physiologic salt solution and heart stimulants.

January 28: His condition was fairly good; temperature was 99.2 and pulse 98 in the morning; in the evening the temperature was 101.2 and pulse 116. There was profuse serous drainage from the wound; the abdomen was slightly distended. There was a small bowel movement.

January 29: His condition was fairly good; temperature was 98 and pulse 88 in the morning. Temperature was 99.8 and pulse 100 in the evening. The Penrose drains were removed and glass drains inserted. The discharge became more purulent; there was some tympanites and some flatus was expelled.

From now on improvement continued; there was some infection of the wound, which promptly cleared up. He did not have much temperature after the operation. Diet was extended on February 18. He was sitting up in bed on February 22, and was up and about on February 28. He had a slight relapse, not severe, on February 28, which only lasted eight days. Improvement in all respects followed. He was discharged, cured, on April 12, 1905. Perforation occurred on the fifty-second day of the disease and the tenth day of the relapse. He was operated on 2 hours and 45 minutes after perforation occurred.

Case 11.—Male, aged 43, was admitted to the hospital Feb. 16, 1905, on the tenth day of the disease. He had a light run of typhoid; there was enlarged spleen, and rose spots were present. Temperature ranged from 100.8 in the morning to 101.6 in the evening; the pulse varied from 80 in the morning to 88 in the evening. There was considerable tympanites, but no diarrhea. There was no delirium, but the mental condition was dull throughout.

February 21: His condition in the morning was similar to that of the last few days, but at noon he was taken with severe abdominal pain; there were symptoms of collapse; the pulse became more rapid and weak; the patient was covered with profuse cold sweat; face was pinched; lips were pallid; abdomen was rigid and very painful on pressure; there was partial obliteration of the liver dullness. At 12:30 he had a chill; at 3:15 he was operated on. A lateral incision was made through the right rectus. On opening the abdomen a large amount of pus was found between coils of intestine; the appendix was inflamed and congested and was removed. Two perforations were found within 8 inches of the colon; they were closed with a purse-string suture of linen. About seven inches above this was found a small pin-hole perforation which had been closed by plastic matter and adhesion of the neighboring omentum. All the bowel in this area showed signs of old peritonitis, which must have existed for some days, as the surface of the intestine was eroded and roughened. Pus and other effusions were wiped out carefully with moist gauze, and the peritoneal cavity made apparently clean. One rubber tube drain was inserted to the bottom of the pelvis and five Penrose drains were inserted in various directions. The upper angle of the wound was closed with through-and-through sutures of silkworm gut. The patient was placed in Fowler's position after return to bed. During the afternoon his condition was very critical. At 7 p. m. his temperature was 101.4, pulse 130 and weak. Stimulants were administered, such as enemata of coffee, whisky and normal salt solution, by hypodermoclysis. The wound was dressed in the evening; there was profuse drainage.

February 22: The condition was not so good; at 7 a. m. the temperature was 98 and pulse 134; at 7 p. m. temperature was 98.6 and pulse 140. Some gas was expelled following an enema of turpentine and asafetida. There was profuse seropurulent discharge from drains.

February 23: The condition was worse. At 7 a. m. the temperature by axilla was 102 and pulse 148; at 7 p. m. the temperature by axilla was 100 and pulse 134. He gradually grew weaker. Some gas was expelled following an enema; at 6 p. m. a large amount of blood was passed in the stool.

February 24: Condition was still very bad. At 12:45 a. m. there was more blood in stools; at 2:15 a. m. there was an extensive hemorrhage from bowels; at 7 a. m., axillary temperature was 102, pulse 148 and almost imperceptible. Death at 2:45 p. m.

Perforation occurred on the fifteenth day of the disease; death occurred 74 hours and 45 minutes after perforation and 71 hours and 30 minutes after operation. No autopsy.

THE IMPORTANCE OF THE FIRST STEPS IN ARTIFICIAL FEEDING OF INFANTS, WITH PRACTICAL POINTS ON THE USE OF TOP MILK MIXTURES.

J. C. GITTINGS, M.D.
PHILADELPHIA.

There is probably no cause of chronic digestive disturbances in infancy which can be more easily avoided than improper methods of artificial feeding during the first few months of the infant's life, for this is the time when the average infant receives little, if any, of the physician's attention. Most of the ills of this period are ascribed to immaturity or to innate depravity, and the newborn one is left to work out his salvation with the aid of the attendant nurse and family.

Holt has repeatedly affirmed that under favorable conditions, when he can have entire charge of the infant's feeding from the start, it is exceptional for him to encounter any real difficulty in carrying out the infant's nutrition. This, he thinks, is due as much to the first steps as to his constant subsequent management of the case. Even a brief survey of the subject will reveal certain undeniable facts. The nutrition of the infant, as Chapin points out, should be divided into the preplacental, the placental and the mammary stages, during all of which the infant should be regarded as attached to the mother. At the beginning of the mammary stage the infant's stomach is only rudimentary. The newborn infant is undoubtedly best adapted to its own mother's milk. The nearest approach to this is the milk of another woman, but when we attempt to make use of cow's milk we are at once dealing with a foreign substance, and no amount of modification will make it anything else. This can be well demonstrated by reference to a table published by Heubner.[1]

Time by which Weight is doubled.		Analyses of Milk.			
	Days.	Proteid.	Ash.	Lime.	Phosphoric Acid.
Human......	180	1.0	0.2	0.032	0.047
Horse	60	2.0	0.4	0.124	0.131
Calf	47	3.5	0.7	0.160	0.197
Goat	19	4.3	0.8	0.210	0.322
Pig	18	5.9	..	....	....
Sheep	10	6.5	0.9	0.272	0.412
Cat	9.0	7.0	1.0	....	....
Dog	8.0	7.3	1.3	0.43	0.493
Rabbit	7	10.4	2.4	0.891	0.996

It would seem *that the rapidity of growth is in direct* proportion to the amount of proteid in the milk, and that the natural process of growth in the human species is very slow. The coincidence of a low proteid and a slow growth can mean only that the infant's powers of digestion are unsuited to a stronger, tougher nutriment, and are but slowly developed. Additional proof that growth in the infant is intended to be slow is found in the fact that the proteid of the mother's milk, low as it is, is yet sufficient for the needs of the infant, not only during the whole of the period, during which the weight is doubled—a period varying from four to seven months—but also for a longer time until weaning may be demanded.

The physical characteristics of human milk and cow's milk, when they are introduced into the infant's stomach, have been so often stated as to make repetition unnecessary. No one can overlook the fact that the mechanical action of the curd of cow's milk, apart from the complicated question of its chemical properties, is fundamentally different from the action of the curd of human milk, and, as Chapin well expresses it, this points strongly to the fact that the stomach of each species depends largely for its development on the stimulus afforded by the proteid content of its own proper milk. An absolute liquid diet offers no such stimulus, but in the case of the infant the soft flocculent curd is evidently sufficient for the purpose, which, in the case of the calf, demands coarser excitation for its accomplishment. Of the so-called "vital characteristics" of milk by which we understand that each milk shall be best suited to the young for which Nature intended it, too little is definitely known to make discussion profitable. Statistics are so overwhelming in proof of the fact that the breast-fed infant far surpasses the artificially fed infant in expectancy of life that further comment is unnecessary. The causes for the high mortality of artificially fed infants are undoubtedly the disturbances which may properly be classified as gastro-intestinal, originating in the inability of the infant to digest its food. It is impossible to compute the part played by bacteria in this high mortality, but the underlying cause has probably much to do with physiologicochemical conditions. Of these ills innumerable pages have been written; and since Rotch first drew attention to the science of percentage feeding it would seem that, from the mechanical standpoint, we have almost exhausted the possibilities of the modification of milk to suit the varying powers of the infant's digestion. Sufficient stress, however, has not been laid on the importance of the gradual education of the newborn infant's digestive apparatus to accustom it to the foreign material which it is so often called on to receive.

This problem of the artificial nourishment of the infant often confronts us at the start; or the maternal secretion may suffice for a few days or weeks, but soon has to be aided and, later, substituted, by some handmade mixture. At any period in infancy such substitution of an unnatural for a natural food requires a gradation in the steps of the process. Such a gradation is exceedingly important in the case of the newborn infant. Let us take a concrete example of what often happens in a case in which the nurse is untrained. The mother's supply of milk fails within the first week of the puerperium. The nurse on her own initiative adopts her favorite method of feeding, usually cow's milk and water in equal parts; or perhaps a mixture made with condensed milk. In the haste of the moment and the security engendered by the fact that millions of infants have survived haphazard methods of feeding, the physician may at once dismiss the subject from his mind. Provided there are no undeniably bad results, these feedings are continued at the discretion of the nurse or mother. If this discretion be tempered with common sense or useful experience, all may be well, or the infant may belong to the fortunate class which can digest anything. Frequently, however, the sequence of events will be somewhat as follows: The infant soon begins to exhibit signs of indigestion and is designated by the nurse as a colicky baby. The frequent use of carminatives, with or without opium; mainly, however, the fact that the infant sleeps most of its first days and therefore takes little of the indigestible mixture, will probably tide the case safely over the two or three weeks usually allotted to the puerperium. The baby has grown, the mother is satisfied, the physician is busy and unsuspecting, and the nurse departs more than ever convinced of her ability to feed the newborn. In the absence of any training to the contrary, she is certainly not blameworthy.

Within a few weeks or less the signs of disturbed digestion become too marked to be overlooked. Then will begin the endless succession of infant foods, or the physician will be called. Careful questioning at this time will elicit the fact that the departure from the normal condition of digestion has been present almost from the start. The disturbances may have been ascribed to various recent exciting causes, while the underlying predisposing cause of an unsuitable diet at the outset has been overlooked. Depending on the length of time the mother has persisted in her efforts to feed the child will be its condition when the physician's advice is first asked. There is apt to be fretfulness, if not actual crying. The child is restless, constantly craving, and usually constantly receiving, its nourishment. The degree of disturbance as evidenced by the gastrointestinal symptoms varies, but the stools almost invariably give evidence of indigestion, if not of actual enteritis. There is more or less atrophy, the muscles are flabby, and, in a very large proportion of protracted cases, the signs of rickets are present in a well-marked degree.

The outcome in such a case is uncertain and will depend largely on the child's surroundings and the care it receives. The infant is doubly exposed to the danger of progressive atrophy, of intercurrent disease, especially bronchopneumonia, the acute gastroenteric disorders arising from infected milk or other unsuitable dietary, and the exhaustion incident to the heated term which predisposes to these disorders. Even with the most careful and painstaking treatment, it may be weeks or months before the stools present a normal appearance.

Such types are constantly seen in dispensary practice, although the number among the more fortunate classes is by no means small. The ultimate fate of many of these infants who recover after a protracted attack of indigestion is open to conjecture, as they often pass out of the experience of the individual physician. An interesting field for statistics here presents itself. It is reasonable to suppose that they are at least handicapped in the race of life, even though all traces of their former ill health shall have disappeared within a few years.

The disadvantages of such protracted attacks of indigestion are obvious, but the difficulty of correcting them is equally so. Apart from cases of congenital disease or the ills attendant on the pauperism of many of the city's poor, many of these difficulties may be avoided by proper care at the start of the infant's feeding. It may also be well to call attention to the fact that by no means all the maternal milk secreted is fit for the infants who receive it. Analyses of specimens of milk in many cases in which the maternal supply fails in the first few months of the infant's life will show disturbances in the normal proportions of the ingredients of the milk, which may easily prove to be the starting point of digestive disturbances even before artificial feeding has been attempted. Persistence of indigestion in the case of an infant fed solely on breast milk, therefore, should demand an investigation of that milk.

As is often the case, it is easier to point the moral than to explain how the necessity for it may be avoided. The difficulty for the general practitioner lies in (*a*) the time it takes to instruct the mother, (*b*) the failure of the mother to co-operate, and (*c*) the difficulty in obtaining milk of the necessary purity and of known strength. For the fortunate few who can command laboratory milk, these objections are reduced to a minimum. While there are many useful formulæ for the preparation of milk mixtures they are difficult to memorize or to apply. Into the present discussion these objections do not enter, as the use of scientifically accurate percentage modifications is demanded chiefly as a curative, not necessarily as a preventive measure. To take up, first, the question of the milk supply, it may be stated that unless cream of known composition and of unimpeachable purity can be obtained, nothing can exceed the usefulness of top milk, i. e., the milk and cream which are removed from the top of a quart bottle of milk on which the cream has thoroughly "raised." If it is possible to use certified milk of a definite fat percentage, excellent results can be obtained in the vast majority of cases. The expense of a single quart of certified milk daily, an amount sufficient during the greater part of infancy, is not so prohibitive as it often seems. So much of the ordinary market milk is now provided in jars bottled at the dairy under fairly good conditions of hygiene that, even without the aid of pasteurization, good that of the last few days, but at noon he was taken with severe abdominal pain; there were symptoms of collapse; the pulse became more rapid and weak; the patient was covered with profuse cold sweat; face was pinched; lips were pallid; abdomen was rigid and very painful on pressure; there was partial obliteration of the liver dullness. At 12:30 he had a chill; at 3:15 he was operated on. A lateral incision was made through the right rectus. On opening the abdomen a large amount of pus was found between coils of intestine; the appendix was inflamed and congested and was removed. Two perforations were found within 8 inches of the colon; they were closed with a purse-string suture of linen. About seven inches above this was found a small pin-hole perforation which had been closed by plastic matter and adhesion of the neighboring omentum. All the bowel in this area showed signs of old peritonitis, which must have existed for some days, as the surface of the intestine was eroded and roughened. Pus and other effusions were wiped out carefully with moist gauze, and the peritoneal cavity made apparently clean. One rubber tube drain was inserted to the bottom of the pelvis and five Penrose drains were inserted in various directions. The upper angle of the wound was closed with through-and-through sutures of silkworm gut. The patient was placed in Fowler's position after return to bed. During the afternoon his condition was very critical. At 7 p. m. his temperature was 101.4, pulse 130 and weak. Stimulants were administered, such as enemata of coffee, whisky and normal salt solution, by hypodermoclysis. The wound was dressed in the evening; there was profuse drainage.

February 22: The condition was not so good; at 7 a. m. the temperature was 98 and pulse 134; at 7 p. m. temperature was 98.6 and pulse 140. Some gas was expelled following an enema of turpentine and asafetida. There was profuse seropurulent discharge from drains.

February 23: The condition was worse. At 7 a. m. the temperature by axilla was 102 and pulse 148; at 7 p. m. the temperature by axilla was 100 and pulse 134. He gradually grew weaker. Some gas was expelled following an enema; at 6 p. m. a large amount of blood was passed in the stool.

February 24: Condition was still very bad. At 12:45 a. m. there was more blood in stools; at 2:15 a. m. there was an extensive hemorrhage from bowels; at 7 a. m., axillary temperature was 102, pulse 148 and almost imperceptible. Death at 2:45 p. m.

Perforation occurred on the fifteenth day of the disease; death occurred 74 hours and 45 minutes after perforation and 71 hours and 30 minutes after operation. No autopsy.

THE IMPORTANCE OF THE FIRST STEPS IN ARTIFICIAL FEEDING OF INFANTS, WITH PRACTICAL POINTS ON THE USE OF TOP MILK MIXTURES.

J. C. GITTINGS, M.D.
PHILADELPHIA.

There is probably no cause of chronic digestive disturbances in infancy which can be more easily avoided than improper methods of artificial feeding during the first few months of the infant's life, for this is the time when the average infant receives little, if any, of the physician's attention. Most of the ills of this period are ascribed to immaturity or to innate depravity, and the newborn one is left to work out his salvation with the aid of the attendant nurse and family.

Holt has repeatedly affirmed that under favorable conditions, when he can have entire charge of the infant's feeding from the start, it is exceptional for him to encounter any real difficulty in carrying out the infant's nutrition. This, he thinks, is due as much to the first steps as to his constant subsequent management of the case. Even a brief survey of the subject will reveal certain undeniable facts. The nutrition of the infant, as Chapin points out, should be divided into the preplacental, the placental and the mammary stages, during all of which the infant should be regarded as attached to the mother. At the beginning of the mammary stage the infant's stomach is only rudimentary. The newborn infant is undoubtedly best adapted to its own mother's milk. The nearest approach to this is the milk of another woman, but when we attempt to make use of cow's milk we are at once dealing with a foreign substance, and no amount of modification will make it anything else. This can be well demonstrated by reference to a table published by Heubner.[1]

played by bacteria in this high mortality, but the underlying cause has probably much to do with physiologico-chemical conditions. Of these ills innumerable pages have been written; and since Rotch first drew attention to the science of percentage feeding it would seem that, from the mechanical standpoint, we have almost exhausted the possibilities of the modification of milk to suit the varying powers of the infant's digestion. Sufficient stress, however, has not been laid on the importance of the gradual education of the newborn infant's digestive apparatus to accustom it to the foreign material which it is so often called on to receive.

This problem of the artificial nourishment of the infant often confronts us at the start; or the maternal secretion may suffice for a few days or weeks, but soon has to be aided and, later, substituted, by some hand-made mixture. At any period in infancy such substitution of an unnatural for a natural food requires a gradation in the steps of the process. Such a gradation is exceedingly important in the case of the newborn infant. Let us take a concrete example of what often happens in a case in which the nurse is untrained. The mother's supply of milk fails within the first week of the puerperium. The nurse on her own initiative adopts her favorite method of feeding, usually cow's milk and water in equal parts; or perhaps a mixture made with condensed milk. In the haste of the moment and the security engendered by the fact that millions of infants have survived haphazard methods of feeding, the physician may at once dismiss the subject from his mind. Provided there are no undeniably bad results, these feedings are continued at the discretion of the nurse or mother. If this discretion be tempered with common sense or useful experience, all may be well, or the infant may belong to the fortunate class which can digest anything. Frequently, however, the sequence of events will be somewhat as follows: The infant soon begins to exhibit signs of indigestion and is designated by the nurse as a colicky baby. The frequent use of carminatives, with or without opium; mainly, however, the fact that the infant sleeps most of its first days and therefore takes little of the indigestible mixture, will probably tide the case safely over the two or three weeks usually allotted to the puerperium. The baby has grown, the mother is satisfied, the physician is busy and unsuspecting, and the nurse departs more than ever convinced of her ability to feed the newborn. In the absence of any training to the contrary, she is certainly not blameworthy.

Within a few weeks or less the signs of disturbed digestion become too marked to be overlooked. Then will begin the endless succession of infant foods, or the physician will be called. Careful questioning at this time will elicit the fact that the departure from the normal condition of digestion has been present almost from the start. The disturbances may have been ascribed to various recent exciting causes, while the underlying predisposing cause of an unsuitable diet at the outset has been overlooked. Depending on the length of time the mother has persisted in her efforts to feed the child will be its condition when the physician's advice is first asked. There is apt to be fretfulness, if not actual crying. The child is restless, constantly craving, and usually constantly receiving, its nourishment. The degree of disturbance as evidenced by the gastrointestinal symptoms varies, but the stools almost invariably give evidence of indigestion, if not of actual enteritis. There is more or less atrophy, the muscles are flabby, and, in a very large proportion of protracted cases, the signs of rickets are present in a well-marked degree.

The outcome in such a case is uncertain and will depend largely on the child's surroundings and the care it receives. The infant is doubly exposed to the danger of progressive atrophy, of intercurrent disease, especially bronchopneumonia, the acute gastroenteric disorders arising from infected milk or other unsuitable dietary, and the exhaustion incident to the heated term which predisposes to these disorders. Even with the most careful and [illegible] treatment, it may be weeks or months before [illegible] a normal appearance.

Such types are constantly seen in dispensary practice, although the number among the more fortunate classes is by no means small. The ultimate fate of many of these infants who recover after a protracted attack of indigestion is open to conjecture, as they often pass out of the experience of the individual physician. An interesting field for statistics here presents itself. It is reasonable to suppose that they are at least handicapped in the race of life, even though all traces of their former ill health shall have disappeared within a few years.

The disadvantages of such protracted attacks of indigestion are obvious, but the difficulty of correcting them is equally so. Apart from cases of congenital disease or the ills attendant on the pauperism of many of the city's poor, many of these difficulties may be avoided by proper care at the start of the infant's feeding. It may also be well to call attention to the fact that by no means all the maternal milk secreted is fit for the infants who receive it. Analyses of specimens of milk in many cases in which the maternal supply fails in the first few months of the infant's life will show disturbances in the normal proportions of the ingredients of the milk, which may easily prove to be the starting point of digestive disturbances even before artificial feeding has been attempted. Persistence of indigestion in the case of an infant fed solely on breast milk, therefore, should demand an investigation of that milk.

As is often the case, it is easier to point the moral than to explain how the necessity for it may be avoided. The difficulty for the general practitioner lies in (*a*) the time it takes to instruct the mother, (*b*) the failure of the mother to co-operate, and (*c*) the difficulty in obtaining milk of the necessary purity and of known strength. For the fortunate few who can command laboratory milk, these objections are reduced to a minimum. While there are many useful formulæ for the preparation of milk mixtures they are difficult to memorize or to apply. Into the present discussion these objections do not enter, as the use of scientifically accurate percentage modifications is demanded chiefly as a curative, not necessarily as a preventive measure. To take up, first, the question of the milk supply, it may be stated that unless cream of known composition and of unimpeachable purity can be obtained, nothing can exceed the usefulness of top milk, i. e., the milk and cream which are removed from the top of a quart bottle of milk on which the cream has thoroughly "raised." If it is possible to use certified milk of a definite fat percentage, excellent results can be obtained in the vast majority of cases. The expense of a single quart of certified milk daily, an amount sufficient during the greater part of infancy, is not so prohibitive as it often seems. So much of the ordinary market milk is now provided in jars bottled at the dairy under fairly good conditions of hygiene that, even without the aid of pasteurization, good results may usually be obtained with it. Whenever it is feasible, the personal investigation by the physician of one or more dairies will often enable him to recommend a useful product at market rates. The methods of obtaining the desired percentages in the milk mixtures can be made extremely simple, so as to demand no more time than ordinary prescription writing. The only requirement is the knowledge of the percentages of ingredients in varying amounts of top milk.

According to the analyses published by Holt, the upper portions of quart bottles of good average milk which have stood undisturbed for at least eight hours after bottling, will contain approximately the following percentages:

HOLT'S TABLE.

	Fat.	Sugar.	Proteid.
Upper 16 oz. or 1/2 bottle......	7	4.40	3.40
Upper 11 oz. or 1/3 bottle......	10	4.30	3.30
Upper 8 oz. or 1/4 bottle......	13	4.15	3.25
Upper 6 oz. or 1/5 bottle......	16	4.05	3.20

With Mr. Walter Cuthbert in 1902 and 1904 I made numerous tests of top milk from bottles of a milk which receives the certificate of the Philadelphia Pediatric Society.

Fat in Whole Milk.	Fat in Top of Milk.		
	Min. Fat. Per ct.	Max. Fat. Per ct.	Average Fat. Per ct.
4 to 4.2 per cent.	9.7	10.8	10.0 In 12 oz. of top milk.
5.1 to 5.4 per cent.	12.6	13.2	12.9 In 12 oz. of top milk.
4.1 to 4.5 per cent.	8.4	10.2	9.63 In 14 oz. of top milk.
4.7 to 5.5 per cent.	9.9	12.3	11.57 In 14 oz. of top milk.
4.2 to 4.5 per cent.	7.4	9.0	8.16 In 16 oz. of top milk.
4.7 to 5.5 per cent.	8.5	10.8	9.64 In 16 oz. of top milk.

While the quantities of top milk taken for most of our examinations did not correspond with those given by Holt, our test of a whole milk of a fat percentage of 4.2 gave 7.4 per cent. of fat in the upper 16 ounces—a result which is sufficiently close to prove his point when we consider that the average milk to which he alludes probably ran as much below as it did above 4 per cent. of fat. In an isolated test of an average market milk of a fat percentage of 3.8, we found 12.6 per cent. fat in the upper eight ounces, which again substantiates Holt's figures.

The great variability of the fat percentage in top milk is well known. Even the advocates of cream-milk mixtures, however, can not claim immunity from this variation, for this ingredient fat is notoriously uncertain. The dilution of top milk necessary for young infants will materially reduce this variation in the fat content, and the healthy infant will usually experience no difficulty with it.

It is with the proteid, however, that there is need of greater accuracy, and with this ingredient of milk we fortunately find much less liability to variation than is the case with the fat. In many of the analyses of former years the proportion of proteid in cow's milk was always given at approximately 4 per cent. More recent works have stated that this percentage is nearer 3.5 than 4 per cent.

The sugar in cow's milk will approximately equal 4.5 per cent. In dealing with top milk, while it must be remembered that the percentage of proteid and sugar will decrease as the percentage of fat increases (see Holt's table), for practical purposes allowance need only be made for this when we use 13 or 16 per cent. cream. For whole milk, skimmed milk, 7 per cent. cream and 10 per cent. cream, the sugar may be calculated as 4.5 per cent. and the proteid as 3.5 per cent.

Of equal importance with the strength of the milk is the knowledge of certain other data in regard to the actual feeding of the infant. The amount and frequency of the meals, as well as the strength of the mixture, are usually left to the nurse or to the mother, whereas the *former count quite as much toward success as the latter.* When an infant is to be taught to take cow's milk it is as easy to accustom it to the proper amount and to the proper interval between feedings as to the milk mixture itself. The rules for the strength of the mixture, the total amount of the mixture and the frequency of the meals are necessarily somewhat arbitrary and are subject to frequent revision. The proper interval should be more strictly adhered to than the amount or strength of the mixture. For example: A three-months-old infant may be taking three ounces of a 3-6-1 mixture every *two and one-half hours, but it may show by evident* dissatisfaction after each meal and by failure to gain in weight that both the amount and strength of the mixture need to be increased, while the interval may usually be bridged over with plain drinking water or barley water given in the bottle. Only in exceptional instances, such as illness, should the interval be lessened. The number of feedings will depend largely on the initial training of the child and on the appropriateness of the mixture to its nutritional needs. Much depends on the manner of training, and for the sake of the mother as well as the child, it would be well at least to attempt a strict adherence to rule. During the first two months of the child's life two night feedings will probably be necessary; from the third to the fifth year one night feeding should be sufficient. Often before the fifth month and always after it night feedings should be abolished; *that is to say, any meal taken later than 9 p. m. or* earlier than 6 a. m., except in cases of illness when the amount of nourishment taken by day may be *insufficient* to tide the child over the nine-hour period. In the case of the healthy infant, however, there can be no more reason for dispensing with a proper interval of rest for the digestive function than there is in the *adult. Frequently* will it be found that the stopping of an injudicious prolongation of the habit of night feeding will at once control an indigestion which no amount of care expended on the day feeding has checked. The number of day feedings will obviously depend also on the sleeping propensities of the child, as will the intervals between the feedings. Persistent habits of sleeping by day and waking at night can only be broken by arousing the infant at the proper intervals.

As an aid to memory, the following condensation of *facts may be advocated*: During the first two months of life the interval between feedings should be two hours; during the second two months the interval should be two and one-half hours. After the fourth month the interval should be three hours. The amount of mixture to be given at different ages may be stated approximately as follows: First week, 1 ounce; second and third weeks, 1½ ounces; fourth week, 2 ounces. From the second to the seventh month, inclusive, the amount of mixture in ounces varies from the number of the month to one in advance of it; for example, third month, from 3 to 4 ounces; fifth month, from 5 to 6 ounces, etc. Rarely will it be advisable or necessary *to administer more than* 8 ounces at one feeding. Finally, there should be considered the strength of the milk mixture.

It may be assumed that the average healthy infant can digest whole cow's milk at the age of from 8 to 12 months. Infants above the normal may, and certainly do, accomplish this at an earlier age, but the risk of such forcing is not justified by the results, and, indeed, is often disastrous. For certain infants, the digestion of whole milk at any time during the first two years of life may prove to be a hopeless attainment. For such the limits of top-milk mixtures and of this discussion are alike insufficient. For the average, however, the end to be attained in milk modification is a 4-4.5—3.5 basis (whole milk) at the age of from 8 to 12 months.

The first three months are the crucial period and the mistake most commonly made is when the artificial feeding is begun. During this period the strength of the first milk mixtures should be as follows: Fat, 1.5 to 2 per cent.; sugar, from 4 to 5 per cent.; proteid, from 0.5 to 0.75 per cent. The strength of this mixture must naturally be increased quite rapidly at first as compared with later mixtures. By the third or fourth month, the fat should have been increased to from 2.5 to 3.5 per cent. sugar to 6 per cent. and the proteid to from 1.5 to 2.5 per cent. From the eighth to the twelfth month the strength of whole milk should have been reached.

The cardinal points for guidance in increasing the strength of the mixtures are the condition of the child's digestion, the gain in weight and what may be called the "subjective needs" of the child itself. The latter, that is, the hunger of the child may safely be consulted provided the digestive function is not impaired. The spurious hunger of infants with chronic gastroenteric disorders must not be confounded with the healthy appetite.

In this connection it is important to remember that the good or bad effects of any given formula *must not* be judged too hastily. Except in the presence of an active diarrhea or the result of a purgative, the appearance of a stool gives evidence of a meal taken at least twenty-four hours before, or even longer. It is also important to remember that no single stool, but a succession of stools, is necessary to prove a point. A change in the milk formula must, therefore, not be made too hastily.

The importance of [illegible] hild can safely be reiterated. Stated [illegible] child should gain from 5 to 7 ounces a week during the first four months of life, from 3 to 5 ounces during the fifth, sixth and seventh months, and from 2 to 4 ounces from the eighth to the twelfth month. Daily weighings are apt to be misleading. At first bi-weekly, and later weekly weighings are sufficient. The clothing factor must be the same at each observation or else strict allowance must be made for it; weighings should be made as nearly as possible at corresponding times, both as to the hour of the day and the interval that has elapsed since the last feeding.

As has been said, one of the greatest difficulties in the application of our knowledge of infant feeding lies in the time required to expound the essentials of this knowledge in an intelligible form to the mother. The knowledge of the strength of the top milks to be used is requisite. To repeat, the upper sixteen ounces of average milk (4 per cent. fat), contains, approximately, 7 per cent. fat; the upper 11 ounces, 10 per cent. fat; the upper 8 ounces, 13 per cent. fat, and the upper 6 ounces, 16 per cent. fat.

Speaking of the different top milks as 16 per cent. cream, 13 per cent. cream, 10 per cent. cream, etc., it is interesting to note that the proportion of fat to proteid in 7 per cent. cream is approximately, as 2 to 1; in 10 per cent. cream as 3 to 1; in 13 per cent. cream as 4 to 1, and in 16 per cent. cream as 5 to 1. In whole milk, which contains 4 per cent. fat, the proportion is approximately 1 to 1.

The determination of the proportion of ingredients of a mixture to be made with the above-described top milks becomes merely a matter of simple division. For example, diluting 7 per cent. cream with equal parts of water will give us a mixture of half the strength or fat 3.5 per cent,. sugar 2.25 per cent., proteid 1.75 per cent. One part of 7 per cent. cream with two parts of diluent will yield a mixture of one-third strength, or fat 2.3 per cent., sugar 1.50 per cent., proteid 1.1 per cent. In both of these instances the proportion of fat to proteid is as 2 to 1. The same dilutions of 10 per cent. cream with one or two parts of water would give, respectively, 5 per cent. and 3.3 per cent. of fat, the sugar and proteid remaining the same. In like manner, a number of mixtures may be devised, working only on the few elemental figures given. Refinements in the method may be introduced with the use of skimmed milk or that portion of the contents of the quart bottle which is left after all the cream has been removed with the top milk. Skimmed milk is practically fat free, the sugar and proteid being approximately the same as in top milk.

It remains to consider the question of the sugar. The amount of this ingredient necessary to bring the proportion up to the amount required for the proper nourishment of the infant is from 5 to 7 per cent., and to obtain this we need only employ a 3, 4 or 5 per cent. sugar solution as a diluent instead of plain water. A 5 per cent. sugar solution obviously would consist of 1 ounce of sugar with 20 ounces of water, or fractions thereof. A 4 per cent. sugar solution consists of 1 ounce of sugar in 25 ounces of water; a 3 per cent. of sugar solution consists of 1 ounce of sugar in 33 ounces of water. Three level tablespoonsful of lactose approximately will equal 1 ounce. With these data at our command we may best demonstrate the method of using them by citing a concrete instance. Suppose an infant of normal development is to be fed artificially at the end of the first week of its life. The proportion of fat in the mixture should be about 1.5 per cent., sugar 4 per cent., and the proteid .75 per cent. The amount of the mixture to be given at each feeding should be about 1 ounce, and there should be prepared from ten to twelve feedings for the twenty-four hours' consumption.

For the preparation of the mixture, beside the quart bottle of milk on which the cream has been left undisturbed, there will be needed a supply of lactose or milk sugar, a six or eight-ounce graduate or other receptacle of known capacity, a supply of boiled water, a quart fruit jar and a bowl for mixing. With care it is possible to pour off the upper 10 to 16 ounces of a quart bottle of milk in such a manner as to secure practically all the cream, but more desirable, and for smaller quantities indispensable, is the 1-ounce milk dipper, of which there are several designs on the market. To obviate the possible danger of the milk dipper it should be scalded immediately after, as well as before, its use. All the other utensils should likewise be scalded before being used.

In the case above noted, our instructions to the nurse or mother would be given in writing as follows:

Remove the upper sixteen ounces of top milk. Dissolve one results may usually be obtained with it. Whenever it is feasible, the personal investigation by the physician of one or more dairies will often enable him to recommend a useful product at market rates. The methods of obtaining the desired percentages in the milk mixtures can be made extremely simple, so as to demand no more time than ordinary prescription writing. The only requirement is the knowledge of the percentages of ingredients in varying amounts of top milk.

According to the analyses published by Holt, the upper portions of quart bottles of good average milk which have stood undisturbed for at least eight hours after bottling, will contain approximately the following percentages:

HOLT'S TABLE.

	Fat.	Sugar.	Proteid.
Upper 16 oz. or 1/2 bottle......	7	4.40	3.40
Upper 11 oz. or 1/3 bottle......	10	4.30	3.30
Upper 8 oz. or 1/4 bottle......	13	4.15	3.25
Upper 6 oz. or 1/5 bottle......	16	4.05	3.20

With Mr. Walter Cuthbert in 1902 and 1904 I made numerous tests of top milk from bottles of a milk which receives the certificate of the Philadelphia Pediatric Society.

Fat in Whole Milk.	Fat in Top of Milk.		
	Min. Fat. Per ct.	Max.Fat. Per ct.	Average Fat. Per ct.
4 to 4.2 per cent.	9.7	10.8	10.0 In 12 oz. of top milk.
5.1 to 5.4 per cent.	12.6	13.2	12.9 In 12 oz. of top milk.
4.1 to 4.5 per cent.	8.4	10.2	9.63 In 14 oz. of top milk.
4.7 to 5.5 per cent.	9.9	12.3	11.57 In 14 oz. of top milk.
4.2 to 4.5 per cent.	7.4	9.0	8.16 In 16 oz. of top milk.
4.7 to 5.5 per cent.	8.5	10.8	9.64 In 16 oz. of top milk.

While the quantities of top milk taken for most of our examinations did not correspond with those given by Holt, our test of a whole milk of a fat percentage of 4.2 gave 7.4 per cent. of fat in the upper 16 ounces—a result which is sufficiently close to prove his point when we consider that the average milk to which he alludes probably ran as much below as it did above 4 per cent. of fat. In an isolated test of an average market milk of a fat percentage of 3.8, we found 12.6 per cent. fat in the upper eight ounces, which again substantiates Holt's figures.

The great variability of the fat percentage in top milk is well known. Even the advocates of cream-milk mixtures, however, can not claim immunity from this variation, for this ingredient fat is notoriously uncertain. The dilution of top milk necessary for young infants will materially reduce this variation in the fat content, and the healthy infant will usually experience no difficulty with it.

It is with the proteid, however, that there is need of greater accuracy, and with this ingredient of milk we fortunately find much less liability to variation than is the case with the fat. In many of the analyses of former years the proportion of proteid in cow's milk was always given at approximately 4 per cent. More recent works have stated that this percentage is nearer 3.5 than 4 per cent.

The sugar in cow's milk will approximately equal 4.5 per cent. In dealing with top milk, while it must be remembered that the percentage of proteid and sugar will decrease as the percentage of fat increases (see Holt's table), for practical purposes allowance need only be made for this when we use 13 or 16 per cent. cream. For whole milk, skimmed milk, 7 per cent. cream and 10 per cent. cream, the sugar may be calculated as 4.5 per cent. and the proteid as 3.5 per cent.

Of equal importance with the strength of the milk is the knowledge of certain other data in regard to the actual feeding of the infant. The amount and frequency of the meals, as well as the strength of the mixture, are usually left to the nurse or to the mother, whereas the former count quite as much toward success as the latter. When an infant is to be taught to take cow's milk it is as easy to accustom it to the proper amount and to the proper interval between feedings as to the milk mixture itself. The rules for the strength of the mixture, the total amount of the mixture and the frequency of the meals are necessarily somewhat arbitrary and are subject to frequent revision. The proper interval should be more strictly adhered to than the amount or strength of the mixture. For example: A three-months-old infant may be taking three ounces of a 3-6-1 mixture every two and one-half hours, but it may show by evident dissatisfaction after each meal and by failure to gain in weight that both the amount and strength of the mixture need to be increased, while the interval may usually be bridged over with plain drinking water or barley water given in the bottle. Only in exceptional instances, such as illness, should the interval be lessened. The number of feedings will depend largely on the initial training of the child and on the appropriateness of the mixture to its nutritional needs. Much depends on the *manner of training*, and for the sake of the mother as well as the child, it would be well at least to attempt a strict adherence to rule. During the first two months of the child's life two night feedings will probably be necessary; from the third to the fifth year one night feeding should be sufficient. Often before the fifth month and always after it night feedings should be abolished; that is to say, any meal taken later than 9 p. m. or earlier than 6 a. m., except in cases of illness when the amount of nourishment taken by day may be insufficient to tide the child over the nine-hour period. In the case of the healthy infant, however, there can be no more reason for dispensing with a proper interval of rest for the digestive function than there is in the adult. Frequently will it be found that the stopping of an injudicious prolongation of the habit of night feeding will at once control an indigestion which no amount of care expended on the day feeding has checked. The number of day feedings will obviously depend also on the sleeping propensities of the child, as will the intervals between the feedings. Persistent habits of sleeping by day and waking at night can only be broken by arousing the infant at the proper intervals.

As an aid to memory, the following condensation of facts may be advocated: During the first two months of life the interval between feedings should be two hours; during the second two months the interval should be two and one-half hours. After the fourth month the interval should be three hours. The amount of mixture to be given at different ages may be stated approximately as follows: First week, 1 ounce; second and third weeks, 1½ ounces; fourth week, 2 ounces. From the second to the seventh month, inclusive, the amount of mixture in ounces varies from the number of the month to one in advance of it; for example, third month, from 3 to 4 ounces; fifth month, from 5 to 6 ounces, etc. Rarely will it be advisable or necessary to administer more than 8 ounces at one feeding. Finally, there should be considered the strength of the milk mixture.

It may be assumed that the average healthy infant can digest whole cow's milk at the age of from 8 to 12 months. Infants above the normal may, and certainly do, accomplish this at an earlier age, but the risk of such forcing is not justified by the results, and, indeed, is often disastrous. For certain infants, the digestion of whole milk at any time during the first two years of life may prove to be a hopeless attainment. For such the limits of top-milk mixtures and of this discussion are alike insufficient. For the average, however, the end to be attained in milk modification is a 4-4.5—3.5 basis (whole milk) at the age of from 8 to 12 months.

The first three months are the crucial period and the mistake most commonly made is when the artificial feeding is begun. During this period the strength of the first milk mixtures should be as follows: Fat, 1.5 to 2 per cent.; sugar, from 4 to 5 per cent.; proteid, from 0.5 to 0.75 per cent. The strength of this mixture must naturally be increased quite rapidly at first as compared with later mixtures. By the third or fourth month, the fat should have been increased to from 2.5 to 3.5 per cent. sugar to 6 per cent. and the proteid to from 1.5 to 2.5 per cent. From the eighth to the twelfth month the strength of whole milk should have been reached.

The cardinal points for guidance in increasing the strength of the mixtures are the condition of the child's digestion, the gain in weight and what may be called the "subjective needs" of the child itself. The latter, that is, the hunger of the child may safely be consulted provided the digestive function is not impaired. The spurious hunger of infants with chronic gastroenteric disorders must not be confounded with the healthy appetite.

In this connection it is important to remember that the good or bad effects of any given formula must not be judged too hastily. Except in the presence of an active diarrhea or the result of a purgative, the appearance of a stool gives evidence of a meal taken at least twenty-four hours before, or even longer. It is also important to remember that no single stool, but a succession of stools, is necessary to prove a point. A change in the milk formula must, therefore, not be made too hastily.

The importance of weighing the child can safely be reiterated. Stated roughly, a healthy child should gain from 5 to 7 ounces a week during the first four months of life, from 3 to 5 ounces during the fifth, sixth and seventh months, and from 2 to 4 ounces from the eighth to the twelfth month. Daily weighings are apt to be misleading. At first bi-weekly, and later weekly weighings are sufficient. The clothing factor must be the same at each observation or else strict allowance must be made for it; weighings should be made as nearly as possible at corresponding times, both as to the hour of the day and the interval that has elapsed since the last feeding.

As has been said, one of the greatest difficulties in the application of our knowledge of infant feeding lies in the time required to expound the essentials of this knowledge in an intelligible form to the mother. The knowledge of the strength of the top milks to be used is requisite. To repeat, the upper sixteen ounces of average milk (4 per cent. fat), contains, approximately, 7 per cent. fat; the upper 11 ounces, 10 per cent. fat; the upper 8 ounces, 13 per cent. fat, and the upper 6 ounces, 16 per cent. fat.

Speaking of the different top milks as 16 per cent. cream, 13 per cent. cream, 10 per cent. cream, etc., it is interesting to note that the proportion of fat to proteid in 7 per cent. cream is approximately, as 2 to 1; in 10 per cent. cream as 3 to 1; in 13 per cent. cream as 4 to 1, and in 16 per cent. cream as 5 to 1. In whole milk, which contains 4 per cent. fat, the proportion is approximately 1 to 1.

The determination of the proportion of ingredients of a mixture to be made with the above-described top milks becomes merely a matter of simple division. For example, diluting 7 per cent. cream with equal parts of water will give us a mixture of half the strength or fat 3.5 per cent,. sugar 2.25 per cent., proteid 1.75 per cent. One part of 7 per cent. cream with two parts of diluent will yield a mixture of one-third strength, or fat 2.3 per cent., sugar 1.50 per cent., proteid 1.1 per cent. In both of these instances the proportion of fat to proteid is as 2 to 1. The same dilutions of 10 per cent. cream with one or two parts of water would give, respectively, 5 per cent. and 3.3 per cent. of fat, the sugar and proteid remaining the same. In like manner, a number of mixtures may be devised, working only on the few elemental figures given. Refinements in the method may be introduced with the use of skimmed milk or that portion of the contents of the quart bottle which is left after all the cream has been removed with the top milk. Skimmed milk is practically fat free, the sugar and proteid being approximately the same as in top milk.

It remains to consider the question of the sugar. The amount of this ingredient necessary to bring the proportion up to the amount required for the proper nourishment of the infant is from 5 to 7 per cent., and to obtain this we need only employ a 3, 4 or 5 per cent. sugar solution as a diluent instead of plain water. A 5 per cent. sugar solution obviously would consist of 1 ounce of sugar with 20 ounces of water, or fractions thereof. A 4 per cent. sugar solution consists of 1 ounce of sugar in 25 ounces of water; a 3 per cent. of sugar solution consists of 1 ounce of sugar in 33 ounces of water. Three level tablespoonsful of lactose approximately will equal 1 ounce. With these data at our command we may best demonstrate the method of using them by citing a concrete instance. Suppose an infant of normal development is to be fed artificially at the end of the first week of its life. The proportion of fat in the mixture should be about 1.5 per cent., sugar 4 per cent., and the proteid .75 per cent. The amount of the mixture to be given at each feeding should be about 1 ounce, and there should be prepared from ten to twelve feedings for the twenty-four hours' consumption.

For the preparation of the mixture, beside the quart bottle of milk on which the cream has been left undisturbed, there will be needed a supply of lactose or milk sugar, a six or eight-ounce graduate or other receptacle of known capacity, a supply of boiled water, a quart fruit jar and a bowl for mixing. With care it is possible to pour off the upper 10 to 16 ounces of a quart bottle of milk in such a manner as to secure practically all the cream, but more desirable, and for smaller quantities indispensable, is the 1-ounce milk dipper, of which there are several designs on the market. To obviate the possible danger of the milk dipper it should be scalded immediately after, as well as before, its use. All the other utensils should likewise be scalded before being used.

In the case above noted, our instructions to the nurse or mother would be given in writing as follows:

Remove the upper sixteen ounces of top milk. Dissolve one level tablespoonful of milk sugar in eleven ounces of boiled water. Put three ounces of top milk and nine ounces of sugar water into a scalded jar, cover and set on ice. Feed one ounce of this mixture every two hours.

In explanation of this, we must remember that the desired feeding for twenty-four hours must consist of 12 ounces of mixture containing approximately 1.50 per cent. fat, 4 per cent. sugar and 0.75 per cent. proteid. The fat-proteid proportion in this being 2 to 1, we may use 7 per cent. cream (upper 16 ounces), which contains 7 per cent. fat, 4.5 per cent. sugar and 3.5 per cent. proteid. A dilution of this four times, or 3 ounces of 7 per cent. cream and 9 ounces of diluent, obviously will give us 1.75 per cent. fat, 1.12 per cent. sugar and 0.87 per cent. proteid; the use of 3 per cent. sugar solution as the diluent will supply the deficiency of sugar.

When we desire to increase the strength of this mixture it may be done conveniently by simply shifting the proportion of cream and sugar solution. For example, three parts of cream and nine parts of diluent (one in four) equals 1.75 per cent. fat, 1.12 per cent. sugar and 0.87 per cent. proteid. Four parts of cream and eight parts of diluent (one in three) equals 2.30 per cent. fat, 1.50 per cent. sugar and 1.16 proteid. By increasing the cream half an ounce (one tablespoonful) at a time and decreasing the sugar solution by the same amount, we would gradually pass from a 1.75, 1.12, 0.87 basis to a 2.33, 1.50, 1.16 basis. The fat-proteid proportion remains the same. When we deal with larger quantities of mixture the change can be made more gradually. For example, in the second week of life the total quantity of mixture becomes 18 ounces instead of 12 (1½ ounces at a feeding). One part of cream and three parts of diluent becomes, therefore, 4½ ounces of cream and 13½ ounces of sugar solution (fat 1.75 per cent. sugar, 1.12 per cent. proteid, 0.87 per cent.). Six ounces of cream and 12 ounces of sugar solution (one in three) would give us 2.33 per cent. 1.50 per cent. sugar and 1.16 per cent. proteid. By increasing the cream half an ounce at a time and decreasing the sugar solution by the same amount we would pass during the second and third week to the latter strength. By the fourth week, when 2 ounces are generally needed at a feeding, the total quantity of mixture becomes 24 ounces instead of 18. Eight ounces of cream and 16 ounces of sugar solution (one in three) still gives us the 2.33, 1.50, 1.16 basis, which will probably be sufficient for the second month. By the third month, when the interval between feedings will be increased to two and a half hours with 3 ounces at a feeding, the total feedings will not exceed ten; and 30 ounces of mixture will be sufficient. Ten ounces of cream and 20 ounces of sugar solution (one in three) may then be gradually increased, one-half ounce at a time, to 15 ounces each of cream and sugar solution, which would represent 3.5 per cent. fat, 2.25 per cent. sugar and 1.75 per cent. proteid. As an example of some of the formulæ which can be obtained with milk and top milk the table in the preceding column may be cited.

	Fat.	Sugar.	Proteid.
One part of 4 per cent. milk with one part of diluent (1 in 2)........................	2.00	2.75	1.75
One part of 5 per cent milk with one part of diluent (1 in 2)........................	2.50	2.75	1.75
One part of 7 per cent. cream with one part of diluent (1 in 2).....................	3.50	2.75	1.75
One part of 4 per cent. milk with two parts of diluent (1 in 3).....................	1.33	1.50	1.16
One part of 5 per cent. milk with two parts of diluent (1 in 3).....................	1.66	1.50	1.16
One part of 7 per cent cream with two parts of diluent (1 in 3).....................	2.33	1.50	1.16
One part of 10 per cent cream with two parts of diluent (1 in 3)................	3.33	1.50	1.16
One part of 4 per cent. milk with three parts of diluent (1 in 4).....................	1.00	1.16	.87
One part of 5 per cent. milk with three parts of diluent (1 in 4).....................	1/25	1.16	.87
One part of 7 per cent. cream with three parts of diluent (1 in 4)................	1/75	1.16	.87

One part of 13 per cent. cream, one part of skimmed milk, one part of diluent (1/3 fat, 2/3 sugar and proteid)............	4.30	3.00	2.33
One part of 10 per cent. cream, two parts of skimmed milk (1/3 fat, sugar and proteid same as in milk.) (None.)..........	3.9	4.50	3.50

The mother must be instructed to thoroughly mix the contents of the jar by shaking before pouring out the feeding and to warm the latter by standing the feeding bottle in hot water before administering the milk. The *preparation of all the bottles necessary for the day's feeding* at the time of making the mixture is distinctly desirable, but can only be advocated in the case of enthusiastic co-operation on the part of the mother.

If the foregoing instructions seem complicated at first reading a few moment's reflection will surely prove the reverse to be true. The data to be memorized are the fundamental strengths of milk and certain creams; the rest is simple division.

IMPROVED OPERATION FOR HYPOSPADIAS INVOLVING THE GLANS AND PENILE PORTION OF THE URETHRA.

J. COPLIN STINSON, M.D.
SAN FRANCISCO.

Hypospadias is a condition due to want of fusion of the lips of the urogenital sinus which go to form the urethra and varies in degree from an unduly large meatus to a completely cleft urethra. This deformity, unlike the somewhat similar condition of epispadias, never extends into the bladder, and incontinence of urine is, therefore, not one of its complications.

In hypospadias affecting the glans the inconvenience may be so slight as to be almost unnoticeable, but it increases the further back the cleft extends. There are two troubles in connection with hypospadias: In the first place the urethral opening is always unduly narrow, sometimes extremely so, and there is, therefore, a certain amount of back pressure from which serious results may follow. The second trouble is that the penis is always curved downward when the cleft in the urethra extends any distance back, and this incurvation is greater the further back the cleft extends. Attempts to straighten the organ are resisted by a fibrous band or bands corresponding to the remains of the urogenital groove and lying in the position of the normal urethral roof. This incurvation produces much inconvenience, as the urine is projected against the down-curved organ, the stream is broken up and the patient may be constantly wetted. In children this often gives rise to troublesome eczema in addition to the offensive ammoniacal decomposition of the urine on the clothes. When the urethral orifice is situated further back than the glans, coitus is often practically impossible, as proper erection is prevented by the incurvation. When the cleft extends still further back and is associated with a cleft scrotum, the condition closely resembles hermaphrodism and the rudimentary organ is quite useless.

The cases met with may be divided into three groups:

(1) Those in which the fissure is limited to the glans; (2) those in which the cleft is in the penile portion and the orifice of the urethra opens anteriorly to the scrotum, and (3) those in which the scrotum is cleft and the urine issues from an opening in the perineum. The first two groups of hypospadias are considered here. I have reviewed the articles of Cheyne and Burgland, Duplay, R. Hamilton, C. Beck and others on this subject, but do not intend to review their methods. I wish, however, to acknowledge many valuable points taken from these writers and used in the construction of this paper.

Treatment is of much avail when the urethral orifice is in front of the scrotum. When the hypospadias simply consists of an unduly large meatus it is often unnecessary to interfere at all. The only point of importance is to make sure that there is no constriction at the orifice of the urethra; should one exist it must be dilated or slit up in the manner used for stricture of the meatus.

When, however, the condition is one either of complete hypospadias of the glans or of a cleft urethra anywhere between the glans and the scrotum, it is necessary to repair the urethral canal. The best time to operate seems to be from 6 to 12 years of age. By that time the patient is amenable to discipline, and there is also plenty of time for the genital organs to develop after the operation, and, moreover, there is not so much likelihood of trouble from erections as there is later. Erections are very likely to be fatal to the success of such an operation.

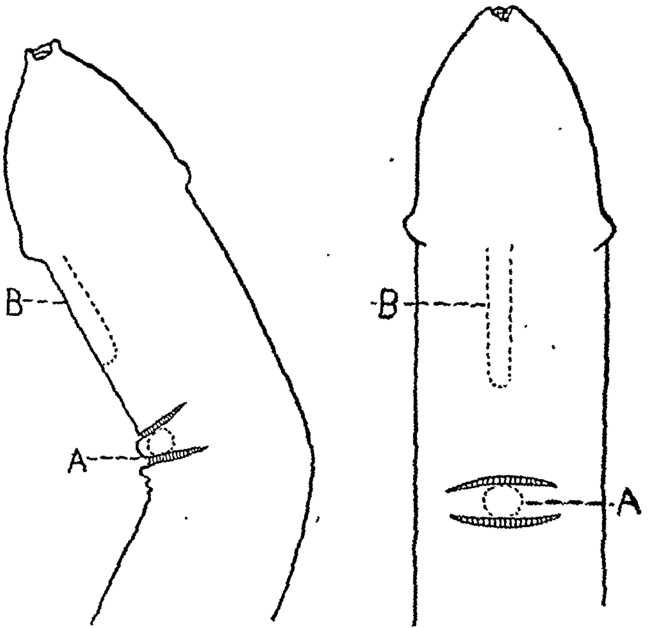

Figure 1. Figure 2.

Figs. 1 and 2 show incurvation, prepuce over glans. A shows urinary orifice in body of penis. B shows short blind groove in body back of glans penis, in particular case reported.

METHOD OF TREATMENT.

Several points have to be attended to in treating a case of hypospadias. The curvature of the penis must be remedied; the natural orifice of the urethra must be made of normal size, and a fresh urethra must be made from this orifice to the end of the glans. The satisfactory way of fulfilling these indications is: 1. To perform an external perineal urethrotomy and insert a large tube into the bladder, thus draining away every drop of urine so that the plastic operations which are done later will heal primarily

For this the *patient* is anesthetized and a Syme's staff is introduced. The staff is passed through the urethra into the bladder, the handle is intrusted to an assistant, and the patient is brought down to the end of the table and put in the lithotomy position. The assistant should hold the staff perfectly vertical and pull the scrotum out of the way. The surgeon makes an inch and one-half median incision about an inch in front of the anus. After the superficial structures have been divided, a forefinger, introduced into the wound, feels for the staff in the urethra. Some blunt dissection and a few touches of the knife expose the urethra, the groove in the narrow portion is felt for, and the point of the knife is slipped along the finger until its point perforates the urethra and engages in the groove. The knife is now made to cut the urethra and an opening is made just sufficient to introduce a 32 French soft rubber catheter. The handle of the staff may now be depressed and the point of the instrument pushed on into the bladder. The staff is withdrawn and a 32 rubber catheter is passed through the wound into the bladder and held there by an adjustable tube holder.

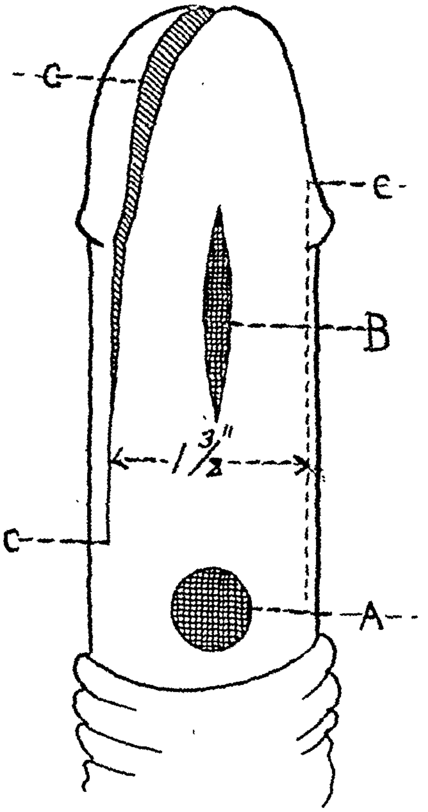

Fig. 3 shows urethral orifice (A) slit up to 33 French separated from its surroundings and edges trimmed evenly. B shows blind groove as in Figs. 1 and 2, but with prepuce well retracted. C shows incisions made for the formation of the new urethra.

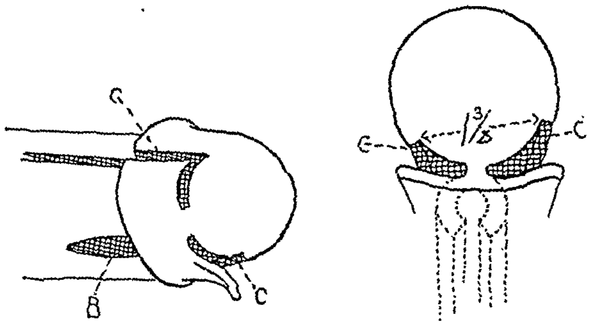

Figure 4. Figure 5.

Fig. 4 shows incisions made and flaps of mucous membrane and skin being dissected up, for new urethra in the glans and body of the penis. C shows raw surface of the glans after lifting flaps. Fig. 5 is the same as Fig. 4, except that dotted lines (D) show flaps brought edge to edge.

It is sometimes difficult to pass the catheter into the bladder, and the easiest plan to insure the instrument passing readily is to slip a Teale's gorget along the groove in the staff before the latter is withdrawn. The gorget passes from the perineal wound into the bladder and serves as a guide along which the point of the catheter is directed. Sometimes the caliber of the urethra is small at the neck of the bladder and has to be dilated to the proper size. This is readily done with a small uterine dilator or a rubber-covered Kohlman's dilator when the tube, *held in place with a tube holder,* is introduced and the bladder properly drained. The wound is dusted with odorless iodoform, and dressings are applied and kept in position by a T bandage.

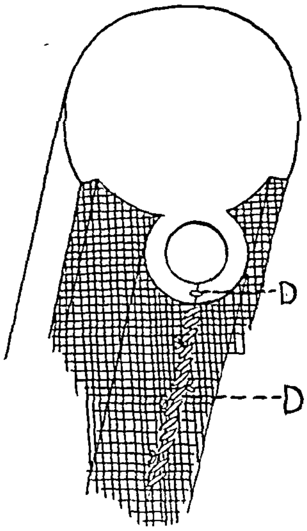

Figure 6.

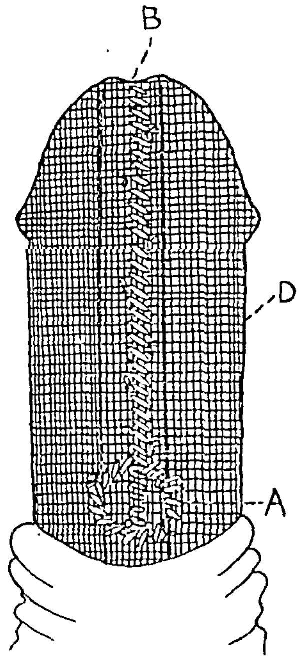

Figure. 7.

Fig. 6 shows the edges of the flaps taken from the glans and body sutured to each other to form new urethra (D). Fig. 7 shows same as Fig. 6, and anastomosis made between the new and old urethral orifices. B shows the end of the new urethra in glans penis. D shows raw surfaces of glans and body whence the flaps have been taken.

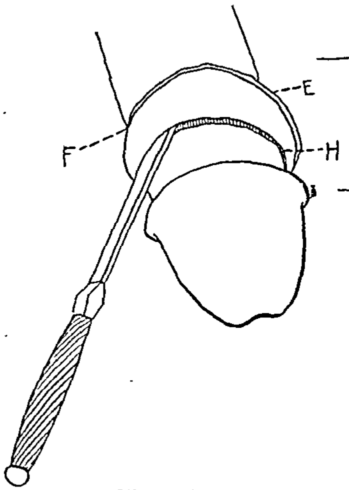

Figure 8.

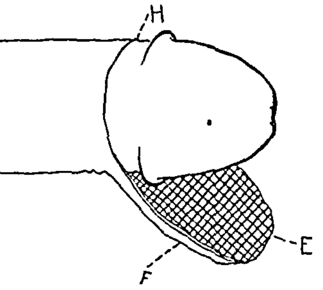

Figure 9.

Fig. 8 shows separation of prepucial hood (F), which consists of two layers, skin (E) and mucous membrane (H). Fig. 9 shows the prepucial hood brought down underneath the glans by carrying the glans through the transverse opening in the prepuce. E shows layer of mucous membrane. F shows layer of skin.

The patient's legs are now extended and the following steps of the operation on the glans and penile portions of the urethra are done, one after the other, under the same anesthesia, viz.: Correcting the incurvation; enlarging and freeing the old meatus; making a new urethra extending from the end of the glans to the old meatus in the body (Figs. 3, 4, 5 and 6); joining by absorbable sutures the new and the old urethral canals (Fig. 7); closing and covering over the raw surfaces on the under surface of the glans and the body of the penis by taking flaps from the rudimentary hood of the prepuce which covers the anterior surface of the glans and body (Figs. 8, 9, 10, 11 and 12); *correcting the deformity* of the convexity or anterior surface of the body by

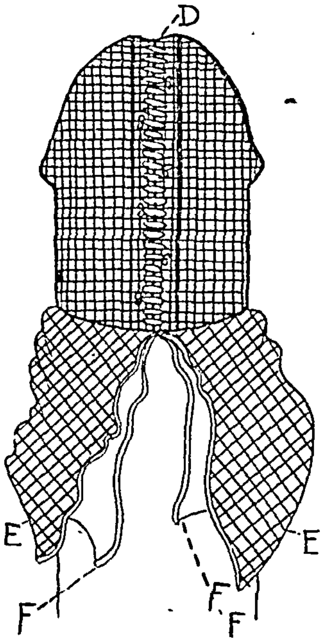

Figure 10.

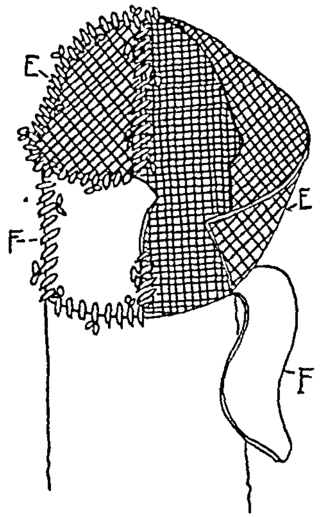

Figure 11.

Fig. 10 shows the newly placed prepuce, cut down the median line and its layers of mucous membrane (E) and skin (F) being dissected from each other ready to be used to cover completely the raw under surfaces of the glans and body of the penis and also to bury the stitches uniting the edges of new urethra and forming anastomosis between the new and old urethras.

Fig. 11 shows layers of mucous membrane (E) and skin (F) separated from each other (shown on the right side of figure) trimmed, put in place in their respective positions and sutured to the vertical cut edges of the glans and body whence the layers were taken to form new urethra (E and F) (shown on left side of figure). The raw surface on left side is completely covered by the mucous and skin layers which are also sutured transversely to each other.

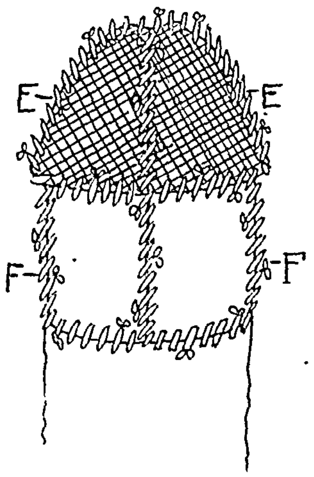

Fig. 12 shows the layers of mucous membrane and skin as in Fig. 11, sutured in their new positions, to the vertical edges, transversely to each other, the cut down the median line sutured, and the skin flaps at their lower parts sutured transversely to the *skin of the body of the penis,* thus completely covering all raw surfaces on the under aspect of the glans and body of the penis. While the cut down the median line was made in this case, usually this should not be done.

making a suitable vertical incision backward from the middle of the incision made to utilize the hood; bringing forward this vertical incision at its angle and suturing it in the same line and continuous with the prepucial or transverse incision, thus eliminating the convexity by shortening the antero-posterior measurement and overcoming the existing lateral constriction by increasing the transverse measurement (Figs. 13, 14 and 15). These steps are, in detail, as follows:

2. To remedy the incurvation (Figs. 1, 2, 3, 13, 14 and 15), the prepuce is drawn back and the urinary orifice in the body usually shows it much narrowed. This is slit up to admit a 33 French sound, and the urethra is dissected from its surroundings, thereby usually exposing the ends of the corpora cavernosa for an inch or so. All constricting fibrous bands are divided by transverse incisions so as thoroughly to straighten the organ (Fig. 3). Care should be taken not to injure the corpora, as it produces free bleeding.

3. Formation of a new urethra in the glans and body and its anastomosis with the dissected up old urethral orifice (Figs. 3, 4, 5, 6 and 7). A 33 French sound is introduced into the slit urinary orifice as a guide, and flaps 1⅜ inches wide of mucous membrane and submucous tissues and sometimes skin and subcutaneous tissues are dissected and taken from the under surface of the glans and body. These flaps are taken by making two vertical parallel incisions 1⅜ inches apart and extending from the end of the glans backward to the level of the dissected urethral orifice. The flaps are dissected loose so that they can be made to meet in the median line without tension over the sound. At each end short transverse incisions are made so as to enable the flaps to be raised. The edges of the flaps are united to each other in the middle line with fine continuous catgut sutures, using the sound as a guide in sewing. These stitches are inserted about eight to an inch and about every fourth is tied with a reef knot. The old urethra is dissected backward for about an inch, and an anastomosis is made between the ends of the new and the old urethras, using fine catgut sutures. Thus a complete canal is formed and in most cases is lined with mucous membrane. In other cases, where the urethra opens further back on the body in front of or shortly in front of the scrotum, skin flaps have to be utilized and substituted to restore the urethral canal in this region. These skin flaps are continuous with the mucous membrane flaps and are in like manner dissected and united in median line to each other so that skin forms the urethral canal where mucous membrane can not be obtained. These skin flaps must be hairless, as otherwise hairs grow in the urethra and cause trouble from their mere presence and the deposit on them of concretions from the urine. When hairs are present on these skin flaps, they should be permanently removed with the electric needle before the operation is undertaken. This must be done to insure satisfactory results, and applies equally in the somewhat similar plastic operations for epispadias (Figs. 3, 4 ,5, 6 and 7).

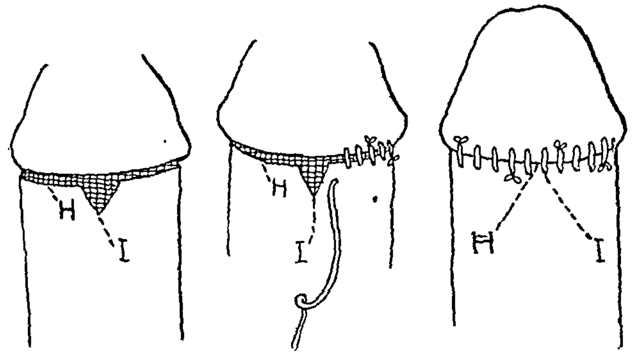

Figure 13. Figure 14. Figure 15.

Figs. 13, 14, 15 show the correction of the convexity and the transverse constrictions on the upper surface of the body by making about an inch long vertical incision in the median line backward from the transverse incision made in separating hood and the dissecting up and bringing forward and suturing it in the same line continuous with the transverse incision. This shortens the antero-posterior measurements and increases the transverse measurement.

4. To cover over the raw surfaces on the glans and body, the hood is utilized (Figs. 8, 9, 10, 11 and 12). The prepuce is put on the stretch and enough of its mucous membrane and skin layers is measured to cover these raw surfaces. A knife is made to cut transversely through both layers of the prepuce about half an inch back of the corona. The incision is enlarged laterally, separating it from the penis for about three-fifths of its extent (Fig. 8). This leaves a transverse opening in the prepuce through which the glans is passed so that the prepuce is brought down underneath to cover the raw area on the under surface of the glans and body (Fig. 9). The newly placed prepuce is cut down the median line and its layers of mucous membrane and skin are dissected from each other and, in turn, are trimmed as required, adjusted and sutured with fine catgut to the vertical cut edges of the glans and body so as to cover the raw surfaces accurately. The cut down the median line and the other edges are sutured accurately in their places with fine catgut stitches (Figs. 10, 11 and 12). It is usually not necessary to make the incision down the median line, but it was done in this case to trim up flaps and remove excess tissue. When the urethra opens in front of or near the scrotum, the raw surface in this area of the body is covered in by a flap taken from the adjacent anterior surface of the scrotum, and twisted on its axis and sutured accurately in place to the edges of the raw surface on this portion of the body so as to cover it completely. The scrotal wound being in loose tissues is readily sutured and thus closed without tension.

5. Correction of the hump or convexity and the transverse constriction on the anterior or upper surface of the body (Figs. 13, 14 and 15) is done by making an inch long vertical incision backward in the median line through the skin and subcutaneous tissues. This incision is at right angles to the transverse one made in separating the hood, and is made long enough so that when its angle is dissected it can be drawn forward and sutured in the same line and continuous with the stitching of the prepucial or transverse incision. This eliminates the convexity by diminishing the antero-posterior measurement of the penis and overcomes the existing lateral constriction in this region by increasing the transverse measurement to the normal condition.

ADVANTAGES OF THE METHOD.

This surgery takes a short time, healing is durable in two to four weeks, all the surgery is done at one sitting, the new canal retains its normal caliber, and its coverings remain in their new positions. The operation is simple, easy to follow, offers every advantage and is followed by the best results—better than any operation hitherto described. The preliminary external urethrotomy and drainage of the bladder allow the plastic surgery to heal without the least trouble. The time of healing in this operation as compared with the other methods is shortened from a year or more to a couple of weeks, it overcomes the necessity of operating in stages as done heretofore, thus avoiding several anesthesias, operations, saving time for both patient and surgeon and avoiding subsequent small operations due to failures by the older methods. In the old methods contractions sometimes occur which render the steps of the operations futile. In this operation the dressings are kept clean and dry, there is no soiling with urine, and it is not necessary to pass any instruments; there is no tension on the wound, no skin grafting, and the method is applicable to all cases.

The deeper structures are sutured separately and accurately with burned absorbable stitches so as to get perfect union. This layer of sutures forms a firm barrier, while the superficial layer forms an additional aid to healing. The character of the buried suture materials is of importance. Sterilized fine catgut or tendon is the most suitable material for burned sutures. If the animal sutures are aseptic the healing is usually satisfactory. Silk or other non-absorbable materials or too heavily chromicized catgut or tendon should not be used as buried sutures, for, although the wounds may heal primarily, yet later sinus or sinuses form and keep discharging until the suture or suturings are thrown off or removed surgically. Such healing also interferes with nice clean union.

I first performed the operation as above described in San Francisco in November, 1904. The patient was about 30 years of age and was referred to me by Dr. Alfred Sander, of San Francisco. The urethra opened anteriorly to the scrotum, about 2½ inches back of the glans on the under surface of the body and a little to the left of the median line. There was a marked incurvation of the penis which produced considerable inconvenience on urinating as the stream was broken and the patient usually wetted. Coitus was practically impossible, as proper erection and entrance were prevented by the incurvations. Surgery was of great avail; healing was primary and durable; the incurvation was overcome; a new urethra was formed; the glandular and penile urethra were built and anastomosis was made between the ends of the new and old urethras; all raw surfaces were covered over; the operation was finished successfully at one sitting and gave perfect functional results. Examination made a couple of months after the operation showed everything satisfactory and canal of normal caliber. After the operation the patient was kept sufficiently under bromids and chloral to control erections, thus greatly favoring primary healing.

533 Sutter Street.

ERRORS IN THE DETERMINATION OF FREE HYDROCHLORIC ACID.*

E. L. WHITNEY, M.D.
Professor of Physiological Chemistry, Baltimore Medical College.
BALTIMORE.

Since Kühne demonstrated the necessity for free hydrochloric acid in peptic digestion many methods have been devised for its detection and determination. This multiplicity of tests is a good indication that none of them exactly fills the requirements. The tests chiefly recommended for the detection of free hydrochloric acid may be divided into two classes, those depending on the change in color produced in some indicator, such as congo-red, dimethyl-amido-azo-benzol, benzopurpurin, tropeolin 00 and others of similar character, and those depending on the coloration produced by the acid on certain organic materials, such as the phloroglucin-vanillin test of Günzberg and the sugar-resorcin test of Boaz.

Against the class of indicators as a whole we may state that, almost without exception, they give a reaction with the organic acids when present in sufficient concentration, as can be easily shown by testing the solutions of the various organic acids with them, the intensity of the reaction varying, of course, with the strength of the acid employed and the degree of delicacy of the end point of the indicator employed. The effect of the acid salts on the indicators is best shown by attempting to titrate a solution of orthophosphoric acid with decinormal alkali, using any of the indicators. According to theory were they not affected by acid salts, the end point should be reached when exactly one-third of the calculated amount of alkali necessary to neutralize all the hydrogen has been added, a condition by no means fulfilled by any of the indicators with which I have experimented. The same test can also be applied by titrating decinormal sulphuric acid with any of these indicators. Were they actually not affected by an acid salt the amount of decinormal alkali required would be exactly half the amount of decinormal sulphuric acid taken, while the result of the experiment shows that an amount of alkali too great for the formation of the acid salt and not enough for the complete neutralization of the acid hydrogen is required. An added disadvantage is that with many of these indicators the end point is frequently obscure, the operator even when trained in chemical work being unable to state definitely the end point.

For qualitative work no fault can be found with the tests of Günzberg and Boaz which give absolutely accurate results.

For quantitative purposes the use of the various indicators is even less reliable than their qualitative indications. As stated under their uses as qualitative tests, they all react to a certain extent with the various organic acids and acid salts and have an indefinite end point. What is still more important with them is their behavior with the so-called combined hydrochloric acid, which is split up as the titration proceeds, the hydrochloric acid and the proteid with which it is combined undergoing a cleavage, the hydrochloric acid thus liberated being also titrated as free hydrochloric. The hydrochloric acid shown by these indicators must, therefore, be composed of the true free hydrochloric acid, varying proportions of the acid salts, and organic acids, and also of a portion of the hydrochloric acid which was originally in combination with the proteids of the gastric contents.

Titration with either the Boaz or Günzberg reagent as an outside indicator requires at least three titrations to insure accurate results, as a considerable amount of the fluid will be used in the preliminary tests outside. In addition they will also show probably at least a small part of the combined hydrochloric acid which splits up as the titration proceeds.

In several years' use of the various indicators I became convinced of the serious errors at times occurring in the ordinary titrations for free hydrochloric acid, titrations showing, for example, a hyperchlorhydria, while the results of treatment did not bear out the results of the titration. When in search of a method which would be free from these sources of error, my attention was called to a method worked out by Hoffmann at Ostwald's suggestion, which seemed to give promise of better results, based, as it was, on an entirely different principle. Hoffmann's method was based on the effect of free hydrogen ions in saponifying methyl or ethyl acetate with the formation of free methyl or ethyl alcohol and acetic acid, the amount of the latter being proportional, other things being equal, to the amount of free hydrogen ion present, and readily titrated with decinormal alkali and an indicator such as phenolphthalein.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Considerable experience with this method has led me to make slight changes in it which, I think, give greater accuracy, though the actual difference is not great. As I carry out the method it may be described thus: Four small, clean, dry flasks are prepared and filled as follows:

No. 1. 10 c.c. gastric juice alone.

No. 2. 10 c.c. gastric juice and 2 c.c. of methyl acetate.

No. 3. 10 c.c. distilled water and 2 c.c. methyl acetate.

No. 4. 10 c.c. N/40 HCl and 2 c.c. methyl acetate.

These are tightly stoppered and placed for at least four hours in a hot air bath at a temperature of between 50 and 55 degrees Centigrade, not at any time exceeding 56, the boiling point of methyl acetate. At the end of at least four hours they are removed and the contents titrated with decinormal alkali, using phenolphthalein as an indicator to the first pink tinge.

No. 1 shows the original acidity plus any increase in the acidity due to standing at a high temperature. This increase does not usually occur, but, as it has taken place in a few cases in my work, it seems to me a reasonable precaution.

No. 2 shows the original acidity plus the increase in acidity due to the formation of acetic acid from the methyl acetate.

No. 3 shows the acetic acid produced by the saponifying action of the distilled water and the small amount of acid which is often present in commercial methyl acetate.

No. 4 shows the acidity of the original N/40 HCl plus the acetic acid liberated from the methyl acetate by the hydrochloric acid.

The calculations from these four determinations are simple and may be illustrated by an example from my notebook:

1. 10 c.c. of gastric juice allowed to stand for five hours at a temperature of 55 degrees required 6.2 c.c. of N/10 KOH to give the first pink tinge with phenolphthalein as an indicator.
2. 10 c.c. of gastric juice plus 2 c.c. of methyl acetate under exactly the same conditions required 64.9 c.c. N/10 KOH.
3. 10 c.c. distilled water plus 2 c.c. methyl acetate under the same conditions required 8.4 c.c. N/10 KOH.
4. 10 c.c. N/40 HCl plus 2 c.c. methyl acetate under the same conditions required 45.85 c.c. N/10 KOH.
5. 10 c.c. of the N/40 HCl, standardized by weighing the amount of silver chlorid produced, required 2.6 c.c. N/10 KOH to neutralize.

Hence:

$64.99 - (6.2 + 8.4) = 50.3.$
$45.85 - (2.6 + 8.4) = 34.85.$
$34.85 : 50.3 :: 0.091 : x.$
$x = 0.1313 =$ per cent. of free HCl.

The sources of error in the Hoffmann method are probably only the following, excluding, of course, the allowable limits of error:

1. Very dilute solutions of hydrochloric acid will give results that are slightly too high on account of the greater dissociation of the acid in dilute solution.

2. The organic acids will also act on the methyl acetate to a slight extent, liberating acetic acid, but this will be at most a very slight error, as the relative strength of acetic acid to hydrochloric is as 0.004 to 1. Lactic acid is as 0.009 to 1.

3. Neutral salts increase slightly the saponifying power of water, the increase, however, falling within the limits of error.

A table is appended showing the results of a number of comparative tests in which a comparison was made between the results afforded by dimethyl and tropeolin 00, with the percentage error based on the saponification number as the correct one.

A CASE OF CHOLESTERIN STONES IN THE BRAIN AND CORD.*

E. E. SOUTHARD, M.D.
Instructor in Neuropathology and Charles Eliot Ware Fellow, Harvard University Medical School.
BOSTON.

Following is a case of multiple *cholesterin* concretions found at autopsy in the brain and cord of a man who showed in life no signs referable thereto. About the masses there was a fibrillary overgrowth of neuroglia.

The patient was under clinical observation at the Boston City Hospital for a little over three weeks in the spring of 1904, on the medical service of Dr. C. F. Withington, whom I wish to thank for the use of his records. The patient was a man of 56, with extensive peripheral arteriosclerosis. For the most part he presented a plain history of cardiac disease growing worse: orthopnea, dyspnea, cyanosis, edema, all coming on in irregular spells, together with gradual enlargement of the heart area and feebleness of heart action, slight albuminuria, a fairly constant demonstration of a soft blowing systolic murmur at the apex transmitted to the axilla, and gradual development of dullness in lower backs. There were no signs directly referable to lesion of the nervous system. A frost-bite of the previous winter had failed to heal well in the right foot. He died a little unexpectedly during a slight apparent improvement in his cardiac symptoms.

---

* From the Pathological Laboratory of the Boston City Hospital.

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The autopsy showed general and extensive arteriosclerosis. The coronary arteries were extensively yellowed and stiffened. The aorta showed diffuse sclerosis with calcification. The sclerosis of the circle of Willis was unusually extensive; and its primary and secondary branches were involved. The heart showed considerable hypertrophy (weight, 615 grams) and diffuse yellowish thickenings of the mitral leaflets. The mitral orifice measured 11.5 cm.; the other valves were not abnormal. The heart muscle showed fine fat droplets in a very few fibers by the Scharlach R. method. Fresh extensive infarctions of the kidney were found, due either to thrombosis or to emboli, which had become in part organized. A hemorrhagic wedge-shaped area in the lower lobe of of the right lung was covered with fresh fibrin. The lungs in general were edematous and congested. The trunk showed little else abnormal save a fibrous pleurisy of the left side and chronic thickenings about the spleen and the liver. The organs of the trunk were examined by Dr. C. J. Duval, whom I wish to thank for his records.

The findings in the head were as follows:

Scalp, calvarium, dura normal. Sinuses contain fluid blood. Pia edematous, notably over vertex. Strips readily. Superficial veins contain no great amount of blood. Carotids yellow and stiff almost uniformly. Circle of Willis, with primary *and sometimes secondary branches, focally yellow and stiff.* Substance shows on external palpation no great variety of consistence. The brain is slightly moister posteriorly. The gyri are fairly firm. On section the substance of the anterior portions of the centrum semiovale in both hemispheres is of normal consistence. The posterior portions of the centrum semiovale are moister and softer than in front; brain substance clings to the knife on section. The edema and softening are more marked on the right hemisphere. At the junction of the gray and white matter of the posterior portion of the left middle tempero-sphenoidal convolution is a coherent, gritty, solid sliver of yellowish-gray material 1.5x1.0x0.3 cm., tightly adherent to the surrounding tissue. There is a similar spheroidal mass about 1 cm. in diameter, imbedded in the gray matter of the right inferior frontal convolution. Adjacent to this inferiorly about 1 cm. distant is a purplish-red, slightly translucent, smoothly cutting and slightly bulging area 1 cm. in diameter, in the inner zone of the cortex. Next this is a small indefinitely bounded area of moist, grumous, opaque, yellowish-gray material, possibly the product of occlusion of a medullary branch of the cortical arterial system; no embolus was found. No similar areas elsewhere. Ventricles contain more than a tablespoonful each of a clear fluid. Choroid plexuses slightly cystiform. Ependyma normal.

Basal ganglia normal and of the usual consistence, except in the middle of the left lenticular nucleus, which presents a stony mass 2 cm. in diameter and slightly flattened from before backward. The mass is closely invested by a thin fibrous capsule and does not shell out. On sawing the middle is found to contain soft opaque grayish material.

Isthmus, bulb and cerebellum normal. Cord: Pia edematous in the middle of the posterior columns of the lower cervical region are small, symmetrical gray areas, suggesting sclerosis. Gray matter everywhere retracts slightly from section surface. On the pia of lower dorsal cord is a single minute white calcified plaque.

Microscopic examination of the organs of the trunk showed a slight brown atrophy of the heart muscle, a hemorrhagic infarct in the lung surrounded by a zone of cocci, chronic passive congestion of liver (extreme) and spleen, infarction of the kidney with *zone of congestion* and leucocyte invasion, an adrenal with high blood content, and a pancreas without notable lesion. There was evidence of arteriosclerosis throughout the organs.

Microscopic examination of the brain and cord showed a moderate subpial gliosis in several places examined. The cortex cerebri, except near the cholesterin masses, was not greatly altered. The tissue of the cord showed very numerous corpora amylacea.

The reaction about the cholesterin masses in the gray matter is slight. A teased specimen from the capsule about the mass in the lenticular nucleus was fixed in formalin and mordanted with picric acid, followed by ammonium bichromate and showed hairlike masses of neuroglia fibrils.

More notable is the reaction about the miliary muscles in the white substance of the cord. These foci are grossly evident in sections of the cord fixed in Zenker's fluid, mounted in paraffin, and stained with phosphotungstic acid hematin. The cholesterin masses have become dissolved away; all that remains of a lesion is the cavity surrounded by a narrow zone in which nerve fibers and myelin sheaths are absent and replaced with a fine felt-work of neuroglia fibrils.

Flakes from various masses and from different portions of the large mass in the lenticular nucleus were found to consist chiefly of smaller and larger cholesterin crystals. No tubercle bacilli could be demonstrated among the crystals. One-half gram of material from the middle of the largest mass was injected into the groin of a guinea-pig, but tuberculosis did not follow.

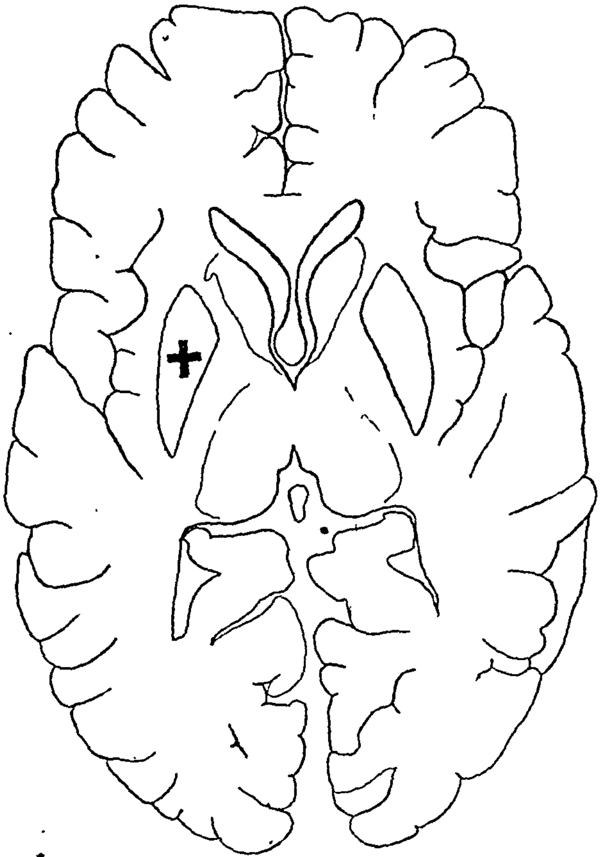

Fig. 1.—Diagram (Dalton, 1885, Series B, Plate vii) to show position of large cholesterin mass.

It is not possible at present to give an adequate explanation of this finding. The condition has nothing in common with cholesteatoma, excepting cholesterin, and fails to show the essential element of cholesteatoma, viz., an accumulation of desquamated epidermal cells. It is not possible to prove a relationship of the deposits with the remains of tubercles, of gummata or of multiple abscesses. It is possible that the deposits are related with old lesions of the blood vessels, perhaps with occlusions or with changes in the vessel walls; at any rate, there is unusually widespread arteriosclerosis in the case. Whatever their origin, it is harder to account for their accumulation in solid tissues than in a cavity like the gall bladder.

The chief interest of the deposits must for the present remain in their association with multiple foci of sclerosis. Deposits like those in the cord may readily be overlooked in routine examinations, and the small spaces occupied by the crystals may be taken for artefacts in preparation. A more careful fresh inspection of central nerve tissues, and especially of the cord, may bring out more of such miliary or larger glioses, to which the attention was drawn in the present case only by the presence of large masses in the gray matter of the cerebrum. The case can hardly be unique. With more cases the relationship of the cholesterin with old foci of suppuration or with vascular lesions may be demonstrated.

SUMMARY.

Male of 56 years. General and extensive arteriosclerosis, extending to gross involvement of some secondary branches of the circle of Willis. Death from heart failure. Small masses of pure or almost pure cholesterin crystals in several parts of the cortical and central ganglionic gray matter and in the white matter of the spinal cord. Largest mass, 2 cm. in diameter, in middle of left lenticular nucleus. Thin capsules due to fibrillary overgrowth of neuroglia surround the masses. The relation of cholesterin to miliary glioses in the spinal cord may readily escape attention.

IMMUNITY.

CHAPTER XXXIV.

BACILLUS OF FRIEDLANDER AND OTHER MEMBERS OF THE CAPSULE-FORMING GROUP.

Capsulated Bacilli.

The bacillus of Friedlander, or *Bacillus pneumoniæ*, is the type of a rather large group of bacteria, called the Friedlander group, or the group of *Bacillus mucosus capsulatus*. In addition to the ability to produce a mucus-like capsule or envelope, they have in general the following characteristics (Abel): short, plump rods, varying in their proportions, having no motion, no flagellæ, no spore formation, and not staining by Gram's method. They form mucus-like masses in cultures, do not liquefy gelatin and are facultative anaërobes. They are widely distributed in nature, vary from innocuousness to extreme pathogenicity for animals, are rarely found in the mouth, nose and bronchi normally (bacillus of Friedlander), one type being a normal inhabitant of the intestines, especially in children (*B. aërogenes capsulatus*). In man three members of the group—they may be the same organism or variations of a type—are of interest from the standpoint of infection: Bacillus of Friedlander, the bacillus of rhinoscleroma and the ozena bacillus.

Pneumonia Caused by Friedlander's Bacillus.

In 129 cases of acute inflammation of the lungs, Weichselbaum found the bacillus of pneumonia nine times, twice with streptococci and once with the diplococcus of pneumonia. The organism causes lobular pneumonia more frequently than lobar. The homogeneous non-granular surface, and the large amount of fluid of a viscid or mucous consistence, are characteristic anatomic features. The alveoli contain massive numbers of the bacilli. The bacillus of Friedlander is found also as the cause of pyelitis, cystitis, pyelonephritis, serous or purulent pericarditis, and pleuritis and menengitis, which may be accompanied by brain abscesses. Meningitis when produced by this organism usually or always is secondary to infection in other parts of the body by the same organism (middle ear and accessory sinuses of the nose).

Rhinoscleroma and Ozena.

An organism of the Friedlander type is found with few exceptions in the tissues in rhinoscleroma, and by many is considered as the cause of the condition. A similar organism is found constantly in the secretions and crusts in ozena. Antiserums of distinct power have not been obtained for members of the group. Prolonged immunization with some strains yields an agglutinating serum of low value. The agglutination reaction is of no value for identification of the different members of the group, nor for clinical diagnosis.

EPIDEMIC CEREBROSPINAL MENINGITIS.

Microbes Causing Meningitis.

Acute inflammation of the meninges may be caused by a number of micro-organisms: *Micrococcus meningitidis*, also called the *Diplococcus intracellularis meningitidis*, or briefly the meningococcus; *Diplococcus pneumoniæ; Streptococcus pyogenes; Staphylococcus pyogenes; Bacillus influenzæ; Bacillus pneumoniæ; Bacillus typhosus; Bacillus coli communis; Bacillus mallei; Bacillus pestis.* The first two of this number, the meningococcus and the pneumococcus, in addition to causing sporadic cases, also produce more or less extensive epidemics of so-called primary meningitis. That the pneumococcus may also cause meningitis secondary to pneumococcus infections in other parts of the body has been mentioned. Also the meningitis caused by the other pyogenic cocci usually is secondary to some other suppurative focus, often the middle ear; that caused by the organisms of typhoid, glanders, plague and influenza occurs during the course of the diseases caused by the corresponding micro-organisms.

Micrococcus Meningitidis.

Previous to 1887 diplococci resembling the *pneumococcus* had been found in the exudate in cases of cerebrospinal meningitis by Foà and Bordoni-Uffreduzzi, by Fraenkel and others. Weichselbaum made similar observations during the same year, and in addition described six cases in which a diplococcus of another nature was present in pure cultures. To the latter he gave the name of *Diplococcus intracellularis meningitidis.* Extensive observations by others, both in Europe and America (Councilman, Mallory and Wright, and others), revealed the presence of the last named organism in many instances, and showed that it is the most common cause of epidemic cerebrospinal meningitis.

The meningococcus resembles the gonococcus closely in that it is usually found in biscuit-shaped pairs, nearly always within pus cells, and does not stain by Gram's method (Weichselbaum). It is properly to be called a micrococcus since it divides in two transverse directions (Albrecht and Gohn); tetrads, small groups and short chains are sometimes seen. However, it forms no striking chains, is non-motile and produces no spores. Growth may be obtained on some of the ordinary media (glycerin agar), in which the organism differs from the gonococcus, but a medium which contains blood or serum is much more favorable. It is an obligate aërobe, grows best at the body temperature and virulence is soon lost under artificial conditions.

It produces a membrane on meat broth with clouding of the medium. Viability is retained for only a few days at room temperature. When dried on paper and exposed to the sunlight it lives no longer than twenty-four hours, in a dark room seventy-two hours (Councilman, Malory and Wright). It is killed by a temperature of 65° C. for thirty minutes (Albrecht and Gohn).

Virulence; Endotoxin.

The meningococcus has little virulence for animals. When injected in sufficient quantity into the peritoneal or pleural cavity of white mice death results in from twenty-four to forty-eight hours, but not when given subcutaneously. Meningitis may be produced by subdural injections, but the disease does not resemble the epidemic meningitis of man. So far as is known at the present time the organism does *not* produce a soluble toxin, but possesses rather an endotoxin.

Infection Atria.

Although the disease is usually spoken of as a primary meningitis, there is reason to believe that it is secondary to an acute rhinitis or acute inflammation of the accessory sinuses or middle ear, at least in many instances. From these places the coccus may readily reach the meninges by way of the lymphatic channels. The organisms have been found repeatedly in the noses of those who were associated with cases of the disease; in such cases an acute rhinitis may be present without the subsequent development of meningitis. Clinical histories of the cases show that the infection commonly is preceded by acute rhinitis. The inflammation in the meninges is always cerebrospinal in its distribution and is characterized by a purulent or fibrino-purulent exudate in which the diplococci are present in varying quantities. Diagnosis may often be established clinically by the microscopic or cultural examination of the cerebrospinal fluid which is removed by lumbar puncture.

Complications and Other Infections.

Acute encephalitis, acute bronchitis, lobar pneumonia and acute arthritis have been observed as complications, in which organisms resembling the meningococcus have been found in a number of instances. An accompanying bronchitis, lobar or lobular pneumonia may be caused by mixed infection with other organisms (pneumococcus, streptococcus, staphylococcus). Since it would be difficult to explain some of these complications except on the basis of metastasis, it seems very probable that the organism reaches the blood stream. Micrococci resembling the meningococcus have been found in acute bronchitis, rhinitis, lobular pneumonia and conjunctivitis, in the absence of cerebral involvement, and it is possible that it may be the cause of independent inflammations in these tissues. Weichselbaum, however, is inclined to doubt the identity of such organisms with the meningococcus. Particularly in cases of bronchitis and lobular pneumonia the coccus may be confused with the *Micrococcus catarrhalis* of Pfeiffer, with which it is identical morphologically.

The extent to which the meningococcus is a normal inhabitant of the nasal mucous membrane is unknown.

Transmission and Contagiousness.

Since the organism seems to be excreted chiefly or only with the nasal discharges, the latter probably are important for transmission of the infection. Because of the low resistance of the organism to desiccation and light, transmission probably is a fairly direct one. This is suggested also by the occasional occurrence of epidemics in institutions. Contagiousness probably is of a rather low order; this is indicated by the distribution of the 111 cases observed by Councilman, Mallory and Wright in Boston, the city being somewhat diffusely infected with very little tendency of the disease to occur in groups of individuals or in several members of a family.

The desirability of avoiding contact with the infected is evident; special prophylactic measures are not known. In the presence of an epidemic the treatment of rhinitis with local antiseptics would suggest itself.

Susceptibility and Immunity.

Children and young people are particularly susceptible to both epidemic and sporadic infections with the meningococcus. Exposure incident to the cold and variable weather of the winter and spring, in which seasons the disease prevails, may be influential in lowering resistance. Second attacks are rare, Councilman, Mallory and Wright collecting only five such examples from the literature. Lipierre immunized animals with cultures and with a toxin, the latter being a glycerin extract of old cultures. Their resistance to infection was said to be increased, and the serum of highly immunized animals was antitoxic, preventive and curative for other animals. Corroborative work is lacking. It is learned from Dr. D. J. Davis privately that the serum in cases of epidemic meningitis shows an increased bactericidal power on the thirteenth day of the disease, and
the agglutinins which develop probably persist
are
little above the normal after two and
ly

strong agglutinins may be obtained by the immunization of rabbits (Jäger and Albrecht and Gohn).

MICROCOCCUS CATARRHALIS.

For some years diplococci resembling the gonococcus and the meningococcus morphologically and in staining reactions have been found in the sputum by a number of observers, and to this coccus Pfeiffer gave the name of *Micrococcus catarrhalis.* It is frequently found in the respiratory passages in influenza-like infections and other inflammatory conditions, and occasionally in lobular pneumonia. It may be associated with the influenza bacillus or the pneumococcus. Among 140 cases of diseases of the respiratory passages Gohn and H. Pfeiffer found it eighty-one times, and M. Neisser demonstrated it in sixteen cases of whooping-cough, in one of measles and scarlet fever, and in two of diphtheria. It loses significance in relation to these diseases, however, since Jündell found it frequently in the mucus of the normal trachea, and Weichselbaum cultivated it frequently from the healthy nasal fossæ. According to Gohn, Pfeiffer and Sederl, "The *Micrococcus catarrhalis*, without the association of other microbes, is able to cause bronchitis and pneumonia with the clinical type of pneumonia due to the pneumococcus. The symptoms caused by the *Micrococcus catarrhalis* do not form a clinical type. They resemble infections by the pneumococcus or the bacillus of Pfeiffer (Influenza)" (Cited by Bezançon and de Jong). Others are not so positive concerning the pathogenic properties of the organism. Its etiologic rôle is not yet well established. It has little pathogenicity for animals, although peritoneal and pleural infection is possible in guinea-pigs.

It differs from the gonococcus and meningococcus in certain cultural characters.

GONORRHEAL INFECTIONS.

The Gonococcus.

A. Neisser discovered the gonococcus in 1879, cultivated it in 1884, and demonstrated its specific relation to gonorrhea by the inoculation of pure cultures into the human urethra. It is a diplococcus, young pairs having a figure-of-eight contour, whereas older pairs show a typical bis or coffee-
bean shape. The organism is non-motile, has læ and
forms no spores. It can be cultivated only which
contain serum, ascitic or a similar fluid. I stain

hours in warm water. They are very susceptible to temperatures above 42 to 43° C. and show very little resistance to antiseptics, particularly the silver salts.

Toxicity and Virulence.

The gonococcus secretes no soluble toxin, but contains an endotoxin or toxic "protein" which causes local and general symptoms in both man and animals. Dead cultures produce an inflammatory exudate in the peritoneal cavity of guinea-pigs and mice, resulting in death if the dose is sufficiently large, and when injected into the urethra of man a temporary inflammation results. An actual infection of any sort can not be produced in animals; the cocci are killed without being permitted to proliferate. The endotoxin is fairly resistant to heat, being destroyed only after prolonged exposure to a temperature of 100° C.

Susceptible Tissues.

In man the mucous membranes and endothelial surfaces are more susceptible to infection than other tissues. The urethra of male and female at all ages, the conjunctiva in the new-born, the vagina, uterus and tubes are probably the most susceptible. Less susceptible are the vagina in older women, especially those who have borne children; the bladder, and in adults the conjunctiva. It is remarkable that there are so few cases of gonorrheal ophthalmia in adults, considering the opportunities for infection. Infection of the mouth, nose and tear sacs is extremely rare. Extension from the urethra to adjacent structures takes place either by way of the surfaces, as in involvement of the prostate, epididymis, glands of Bartholin, uterus, tubes, ovaries, peritoneum, bladder and kidneys, or by way of the lymphatics as in infections of the periurethral tissue or cellular tisue of the pelvis. Infections of the bladder and kidney, and not infrequently the prostate, Fallopian tubes and pelvic tissue are of a mixed character (staphylococcus, streptococcus), but not necessarily so. Arthritis, tendovaginitis, endocarditis, which usually is vegetative but may be ulcerative, are the more common metastatic complications Less frequent are pericarditis, pleuritis, subcutaneous abscesses and iritis. As to whether the cutaneous phenomena sometimes seen are due to metastases or are of purely toxic origin seems to be undetermined. The blood stream may be infected by way of the lymphatics or local blood vessels (gonorrheal thrombosis).

The influence of the enormous phagocytosis of the cocci on the course of gonorrhea is unknown. Since the ingested cocci usually have a typical form and stain well, it would seem that they resist the action of the leucocytic ferments. Likewise the nuclei of the leucocytes usually stain well, hence there is no evidence of a marked toxicity of the cocci for these cells. The mechanical imprisonment of the organisms by the leucocytes may be of influence in localizing the infection.

Urethral Changes.

During the course of gonorrhea "there takes place a pronounced metaplasia of the epithelium in which the cylindrical cells are changed into a more cuboidal and even pavement form." Following this change the gonococci are limited to the surface of the altered epithelium and penetrate more deeply only in the vicinity of the glands and crypts. "Eventually the gonorrheal process is limited to such isolated points and the gonorrhea thereby enters into a chronic stage" (Observations of Finger, cited by Neisser and Scholtz).

Chronic Gonorrhea.

The conditions which cause the subsidence of acute gonorrhea and allow it to persist as a chronic infection have been the subject of much speculation, unproductive for the most part. It is not due to a decrease in the virulence of the cocci since their original infectiousness is retained for others; nor does the local resistance of the mucous membrane reach a high point, since reinfection, or better "superinfection" is possible at any time. A man suffering from chronic gonorrhea and having infected his wife, may again be infected by his wife when the gonorrhea of the latter has become subacute or chronic. It has been suggested that the condition in chronic gonorrhea may be one of "mutual habituation between the mucous membrane and the gonococcus," i. e., a habituation between this particular mucous membrane and this particular gonococcus. Because of prolonged existence under unvarying conditions, the growth energy of the organism may have become less, whereas, if it is placed in a slightly different medium (transference to another individual), its growth energy (ability to proliferate), becomes augmented, and reinfection of the original host with the same strain becomes possible.

It has often been noted that subsequent attacks run a milder course than the primary infection, but susceptibility is always present.

Immunity.

Mendez, Calvino, and also de Christmas have immunized with the coccus or toxic substances prepared from it. By growing the organism in serum bouillon de Christmas prepared a toxin, the toxicity of which was tested by intracerebral injections in the guinea-pig. Immunization of the guinea-pig resulted in a serum with antitoxic properties. Corroborative work has not been published.

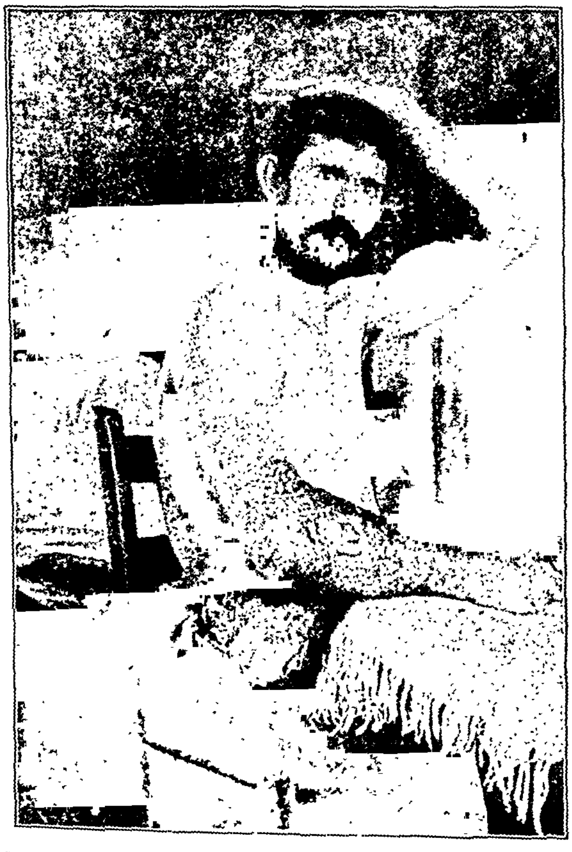
[This series of articles closes with this issue. During the time that they have been appearing in "The Journal" we have received repeated requests to have them reproduced in book form, and the book is now in press. In addition to the subjects considered in the series, the book will contain chapters on infections with the streptococcus, staphylococcus, the diseases of protozoon etiology, and those of doubtful or unknown etiology, including among the latter, smallpox, vaccinia, chickenpox, scarlet fever, measles, German measles, typhus, syphilis, yellow fever, hydrophobia and whooping-cough. The articles, revised and collected in book form, will include a consideration of these diseases from the standpoints of infection and immunity. The book will be ready for delivery in January. The price will be $1.50.]

Clinical Notes

RATTLESNAKE BITE.

W. A. GRESHAM, M.D.
RUSSELLVILLE, ALA.

A man was bitten August 14 by a very large rattlesnake. For about thirty hours it seemed that he was about to succumb at any time, but he suddenly began to improve. He suffered intensely for twenty-four hours. The accompanying



phatic channels. The organisms have been found repeatedly in the noses of those who were associated with cases of the disease; in such cases an acute rhinitis may be present without the subsequent development of meningitis. Clinical histories of the cases show that the infection commonly is preceded by acute rhinitis. The inflammation in the meninges is always cerebrospinal in its distribution and is characterized by a purulent or fibrino-purulent exudate in which the diplococci are present in varying quantities. Diagnosis may often be established clinically by the microscopic or cultural examination of the cerebrospinal fluid which is removed by lumbar puncture.

Complications and Other Infections.

Acute encephalitis, acute bronchitis, lobar pneumonia and acute arthritis have been observed as complications, in which organisms resembling the meningococcus have been found in a number of instances. An accompanying bronchitis, lobar or lobular pneumonia may be caused by mixed infection with other organisms (pneumococcus, streptococcus, staphylococcus). Since it would be difficult to explain some of these complications except on the basis of metastasis, it seems very probable that the organism reaches the blood stream. Micrococci resembling the meningococcus have been found in acute bronchitis, rhinitis, lobular pneumonia and conjunctivitis, in the absence of cerebral involvement, and it is possible that it may be the cause of independent inflammations in these tissues. Weichselbaum, however, is inclined to doubt the identity of such organisms with the meningococcus. Particularly in cases of bronchitis and lobular pneumonia the coccus may be confused with the *Micrococcus catarrhalis* of Pfeiffer, with which it is identical morphologically.

The extent to which the meningococcus is a normal inhabitant of the nasal mucous membrane is unknown.

Transmission and Contagiousness.

Since the organism seems to be excreted chiefly or only with the nasal discharges, the latter probably are important for transmission of the infection. Because of the low resistance of the organism to desiccation and light, transmission probably is a fairly direct one. This is suggested also by the occasional occurrence of epidemics in institutions. Contagiousness probably is of a rather low order; this is indicated by the distribution of the 111 cases observed by Councilman, Mallory and Wright in Boston, the city being somewhat diffusely infected with very little tendency of the disease to occur in groups of individuals or in several members of a family.

The desirability of avoiding contact with the infected is evident; special prophylactic measures are not known. In the presence of an epidemic the treatment of rhinitis with local antiseptics would suggest itself.

Susceptibility and Immunity.

Children and young people are particularly susceptible to both epidemic and sporadic infections with the meningococcus. Lipierre immunized animals with cultures and with a toxin, the latter being a glycerin extract of old cultures. Their resistance to infection was said to be increased, and the serum of highly immunized animals was antitoxic, preventive and curative for other animals. Corroborative work is lacking. It is learned from Dr. D. J. Davis privately that the serum in cases of epidemic meningitis shows an increased bactericidal power on the thirteenth day of the disease, and that the agglutinins which develop probably persist for some time, but are little above the normal after two and one-half years.[1] Fairly strong agglutinins may be obtained by the immunization of rabbits (Jäger and Albrecht and Gohn).

MICROCOCCUS CATARRHALIS.

For some years diplococci resembling the gonococcus and the meningococcus morphologically and in staining reactions have been found in the sputum by a number of observers, and to this coccus Pfeiffer gave the name of *Micrococcus catarrhalis.* It is frequently found in the respiratory passages in influenza-like infections and other inflammatory conditions, and occasionally in lobular pneumonia. It may be associated with the influenza bacillus or the pneumococcus. Among 140 cases of diseases of the respiratory passages Gohn and H. Pfeiffer found it eighty-one times, and M. Neisser demonstrated it in sixteen cases of whooping-cough, in one of measles and scarlet fever, and in two of diphtheria. It loses significance in relation to these diseases, however, since Jündell found it frequently in the mucus of the normal trachea, and Weichselbaum cultivated it frequently from the healthy nasal fossæ. According to Gohn, Pfeiffer and Sederl, "The *Micrococcus catarrhalis*, without the association of other microbes, is able to cause bronchitis and pneumonia with the clinical type of pneumonia due to the pneumococcus. The symptoms caused by the *Micrococcus catarrhalis* do not form a clinical type. They resemble infections by the pneumococcus or the bacillus of Pfeiffer (Influenza)" (Cited by Bezançon and de Jong). Others are not so positive concerning the pathogenic properties of the organism. Its etiologic rôle is not yet well established. It has little pathogenicity for animals, although peritoneal and pleural infection is possible in guinea-pigs.

It differs from the gonococcus and meningococcus in certain cultural characters.

GONORRHEAL INFECTIONS.

The Gonococcus.

A. Neisser discovered the gonococcus in 1879, cultivated it in 1884, and demonstrated its specific relation to gonorrhea by the inoculation of pure cultures into the human urethra. It is a diplococcus, young pairs having a figure-of-eight contour, whereas older pairs show a typical biscuit or coffee-bean shape. The organism is non-motile, has no flagellæ and forms no spores. It can be cultivated only on media which contain serum, ascitic or a similar fluid. Its failure to stain by Gram's method is of great diagnostic importance in the examination of urethral discharges; other organisms resembling the gonococcus are found in the urethra and vagina with great rarity. The reaction loses its differential value in the examination of secretions of the nose, mouth, and, to some extent, of the conjunctiva, where the meningococcus and the *Micrococcus catarrhalis* may be encountered.

Phagocytosis.

In the purulent stage of a gonorrheal infection the cocci are found almost entirely within the leucocytes, whereas in earlier stages, when the discharge is slight and of a mucous character, and also during convalescence, when the secretion again becomes mucous, they are largely extracellular. They are never within the nuclei. The process is one of active phagocytosis in which the cocci play a passive rôle. They occur not only on the surface of the epithelium, but penetrate between and beneath the epithelial cells, and even into the adjacent connective tissue.

Cultivation and Resistance.

In culture media growth is slow and scant, and cultures rarely live longer than one or two weeks, unless they are transplanted to fresh media. On the latter they may be carried through many generations without losing their virulence. When dried they die very quickly, but may live for some hours on linen (towels) or the skin, and for twenty-four hours in warm water. They are very susceptible to temperatures above 42 to 43° C. and show very little resistance to antiseptics, particularly the silver salts.

---

[1] The conclusions of Dr. Davis, in part, are as follows: In five cases of epidemic cerebrospinal meningitis, the meningococcus (Weichselbaum type), was obtained in every case from the cerebrospinal fluid, and in one case from the nose and sputum by cultures. In the other four cases Gram-negative diplococci suggestive of either meningococcus or *Micrococcus catarrhalis* were seen in smears, but were not recovered in cultures. Agglutination of meningococcus by the serum of patients with meningitis occurs in a dilution of 1-50 or higher. The meningococcus grows in some defibrinated normal bloods, but not in others, there being thus an interesting individual variation. In the blood of three meningitis cases it did not grow. Normal human serum is distinctly bactericidal toward the meningococcus. This property is increased in the sera of meningitis cases, and is diminished but not entirely destroyed by heating to 60 C. for thirty minutes. Cerebrospinal fluid acts in much the same way as heated serum. The opsonin content of the blood does not appear to be altered during the course of epidemic meningitis. Normal cerebrospinal fluid does not contain opsonin for meningococci.

The paper of Dr. Davis will be published in full in the forthcoming number of The Journal of Infectious Diseases.

Toxicity and Virulence.

The gonococcus secretes no soluble toxin, but contains an endotoxin or toxic "protein" which causes local and general symptoms in both man and animals. Dead cultures produce an inflammatory exudate in the peritoneal cavity of guinea-pigs and mice, resulting in death if the dose is sufficiently large, and when injected into the urethra of man a temporary inflammation results. An actual infection of any sort can not be produced in animals; the cocci are killed without being permitted to proliferate. The endotoxin is fairly resistant to heat, being destroyed only after prolonged exposure to a temperature of 100° C.

Susceptible Tissues.

In man the mucous membranes and endothelial surfaces are more susceptible to infection than other tissues. The urethra of male and female at all ages, the conjunctiva in the new-born, the vagina, uterus and tubes are probably the most susceptible. Less susceptible are the vagina in older women, especially those who have borne children; the bladder, and in adults the conjunctiva. It is remarkable that there are so few cases of gonorrheal ophthalmia in adults, considering the opportunities for infection. Infection of the mouth, nose and tear sacs is extremely rare. *Extension from the urethra* to adjacent structures takes place either by way of the surfaces, as in involvement of the prostate, epididymis, glands of Bartholin, uterus, tubes, ovaries, peritoneum, bladder and kidneys, or by way of the lymphatics as in infections of the periurethral tissue or cellular tisue of the pelvis. Infections of the bladder and kidney, and not infrequently the prostate, Fallopian tubes and pelvic tissue are of a mixed character (staphylococcus, streptococcus), but not necessarily so. Arthritis, tendovaginitis, endocarditis, which usually is vegetative but may be ulcerative, are the more common metastatic complications Less frequent are pericarditis, pleuritis, subcutaneous abscesses and iritis. As to whether the cutaneous phenomena sometimes seen are due to metastases or are of purely toxic origin seems to be undetermined. The blood stream may be infected by way of the lymphatics or local blood vessels (gonorrheal thrombosis).

The influence of the enormous phagocytosis of the cocci on the course of gonorrhea is unknown. Since the ingested cocci usually have a typical form and stain well, it would seem that they resist the action of the leucocytic ferments. Likewise the nuclei of the leucocytes usually stain well, hence there is no evidence of a marked toxicity of the cocci for these cells. The mechanical imprisonment of the organisms by the leucocytes may be of influence in localizing the infection.

Urethral Changes.

During the course of gonorrhea "there takes place a pronounced metaplasia of the epithelium in which the cylindrical cells are changed into a more cuboidal and even pavement form." Following this change the gonococci are limited to the surface of the altered epithelium and penetrate more deeply only in the vicinity of the glands and crypts. "Eventually the gonorrheal process is limited to such isolated points and the gonorrhea thereby enters into a chronic stage" (Observations of Finger, cited by Neisser and Scholtz).

Chronic Gonorrhea.

The conditions which cause the subsidence of acute gonorrhea and allow it to persist as a chronic infection have been the subject of much speculation, unproductive for the most part. It is not due to a decrease in the virulence of the cocci since their original infectiousness is retained for others; nor does the local resistance of the mucous membrane reach a high point, since reinfection, or better "superinfection" is possible at any time. A man suffering from chronic gonorrhea and having infected his wife, may again be infected by his wife when the gonorrhea of the latter has become subacute or chronic. It has been suggested that the condition in chronic gonorrhea may be one of "mutual habituation between the mucous membrane and the gonococcus," i. e., a habituation between this particular mucous membrane and this particular gonococcus. Because of prolonged existence under unvarying conditions, the growth energy of the organism may have become less, whereas, if it is placed in a slightly different medium (transference to another individual), its growth energy (ability to proliferate), becomes augmented, and reinfection of the original host with the same strain becomes possible.

It has often been noted that subsequent attacks run a milder course than the primary infection, but susceptibility is always present.

Immunity.

Mendez, Calvino, and also de Christmas have immunized with the coccus or toxic substances prepared from it. By growing the organism in serum bouillon de Christmas prepared a toxin, the toxicity of which was tested by intracerebral injections in the guinea-pig. Immunization of the guinea-pig resulted in a serum with antitoxic properties. Corroborative work has not been published.

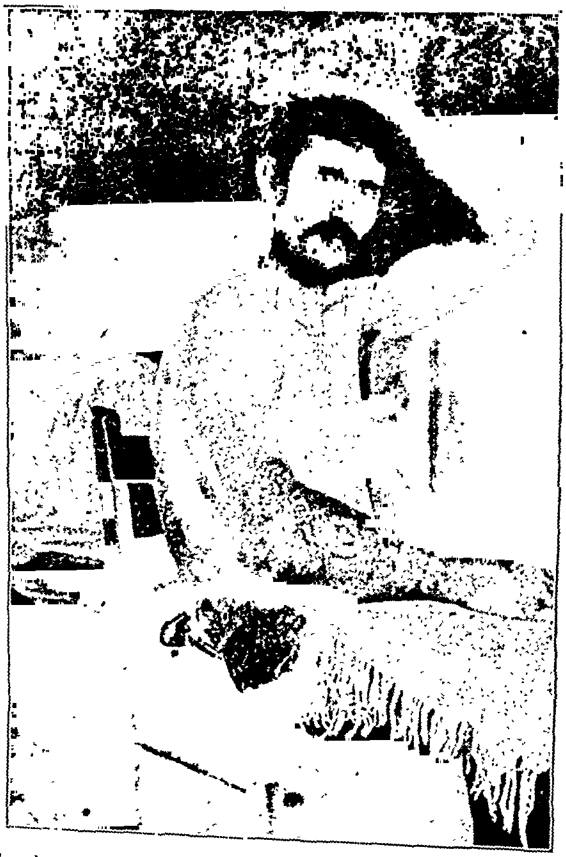
[This series of articles closes with this issue. During the time that they have been appearing in "The Journal" we have received repeated requests to have them reproduced in book form, and the book is now in press. *In addition* to the subjects considered in the series, the book will contain chapters on infections with the streptococcus, staphylococcus, the diseases of protozoon etiology, and those of doubtful or unknown etiology, including among the latter, smallpox, vaccinia, chickenpox, scarlet fever, measles, German measles, typhus, syphilis, yellow fever, hydrophobia and whooping-cough. The articles, revised and collected in book form, will include a consideration of these diseases from the standpoints of infection and immunity. The book will be ready for delivery in January. The price will be $1.50.]

Clinical Notes

RATTLESNAKE BITE.

W. A. GRESHAM, M.D.
RUSSELLVILLE, ALA.

A man was bitten August 14 by a very large rattlesnake. For about thirty hours it seemed that he was about to succumb at any time, but he suddenly began to improve. He suffered intensely for twenty-four hours. The accompanying



photograph was taken August 17, about eighty-two hours after the injury. There was only a little sloughing at the point of injection of the poison, but the man was incapacitated for work about thirty days. As to treatment, the arm was corded tightly, an abundance of whisky was given, and hypodermic injections of strychnin 1/40 g. ever forty-five minutes. He has gone to work and has a good arm.

FATAL CASE OF BLACKWATER FEVER SUPERVENING ON AMEBIC DYSENTERY AND SHOWING MALARIAL PARASITES IN THE BLOOD.[*]

F. CREIGHTON WELLMAN, M.D.
BENGUELLA, WEST AFRICA.

Patient.—Lieutenant M. de G., aged 26, Portuguese, was first seen Dec. 20, 1904.

History.—The patient had been in Africa two years. The first year and a half of this time were spent on the coast, the last six months in the interior. He has never suffered much from malaria nor blackwater fever. Recently he was again sent to the coast, where he spent three weeks. As he was leaving to return to the interior he was attacked with a sharp diarrhea and passed some blood. He recovered in a few days and continued his journey. He has had some looseness of the bowels, with occasional pains, ever since. After his arrival at Bihi fort he had a relapse of the "diarrhea" and was in considerable distress and very weak. He thought he also had some fever, so he came to me for advice.

General Condition.—The patient was thin, weak and feverish. He had no appetite. His tongue was foul. Temperature was 102.4 F., pulse 93, respiration 28. The spleen was slightly enlarged. There was tenderness over the lower bowels. The other organs were normal. At stool there was moderate tenesmus. He had taken no medicine except a diarrhea mixture, ingredients unknown. He considered this the second day of his disease (relapse).

Examination of Feces.—The stools were small and unformed, consisting almost entirely of blood and mucus. There was one moderate-sized slough. Under the microscope many amebæ morphologically identical with *Amœba coli* (Lösch) were seen.

Examination of Blood.—Both fresh and stained specimens were examined, one of each. In the latter two malarial parasites were seen; both were small intracapsular forms. The result of a differential leucocyte count was as follows (about 50 cells counted):

Polymorphonuclears	51.5	per cent.
Lymphocytes	26.	per cent.
Large mononuclear	17	per cent.
Transitional	3	per cent.
Eosinophiles	2	per cent.

The initial and succeeding erythrocyte counts are shown in the chart.

Examination of Urine.—The urine was dark but clear. The spectroscope revealed none of the compounds of hemoglobin. There was a trace of albumin.

Course of the Disease.—The patient was placed in bed (11 a. m.), and small doses of Epsom salts in solution every hour were prescribed. He was placed on liquid diet with a little brandy. In spite of frequent sponging of the body the temperature steadily rose until 5 p. m., when the hemoglobinuria set in.

Re-examination of Urine.—After the hemoglobinuria set in, the urine was re-examined; the color was about like that of porter or stout. There was a dirty-gray sediment, showing under the microscope débris, masses of hemoglobin, and some hyaline and granular casts. The urine was not spectroscoped at first. In later specimens the bands of both oxyhemoglobin and reduced hemoglobin could be seen by shaking up the urine, examining it, adding ammonium sulphid and examining again.

Further Course of the Disease.—*Amœba coli* persisted in the stools (which showed some improvement) throughout the attack, but malarial parasites were not demonstrated in three successive blood examinations. On the morning of the sixth day of the disease the temperature was found to have spontaneously fallen to 101 F. The following day severe hiccoughs set in which nothing availed to control. The patient died at *4:20 p. m. on the twelfth day.*

Treatment.—The treatment pursued was entirely symptomatic and expectant. The saline routine for the dysentery, liquid nourishment and stimulants were administered for the weakness and the usual ineffectual gamut of sedatives and other devices were tried to control the hiccoughs. Quinin was not administered at any period of the attack as hemoglobinuria was feared from the first.

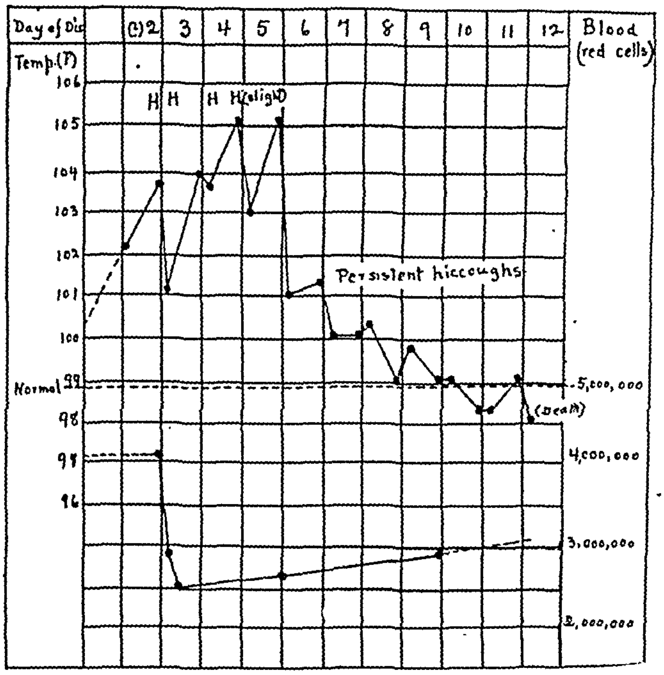


Chart 1.—The blood counts were made on the Thoma-Zeiss hemocytometer. In the first two counts, the blood was also centrifuged and the reading on the hematocrit compared with the result of the actual count. H = hemoglobinuria.

REMARKS.

1. This is the thirty-fourth case which I have studied more or less carefully in West Africa. Of this series 29 patients recovered.

2. The case just recorded is the only instance in which death occurred during the first attack. This may be explained by the previous and synchronous dysentery.

3. In three cases malarial parasites were seen in the blood immediately preceding the hemoglobinuria. In the present case the return of the dysentery probably brought about an explosion of latent malaria, and the two conditions combined were able to produce the physiologic depression and hypotonicity of the blood that invited the intercurrent hemoglobinuria.

4. The question of the relation between malaria and blackwater fever is of great interest, but too intricate to be discussed in a paper of this kind. I believe that they are related in some way, and I have shown that in southern Angola the geographical distribution of *Myzomyia funesta*, Giles (the principal carrier of *H. præcox* in West Africa), severe malaria and hemoglobinuric fever closely coincide. The precise character of the relation between the two diseases (which is disputed by some) has not yet been shown.

CLIMATIC TREATMENT OF CIRCULATORY DISEASE.

LOUIS FAUGERES BISHOP, A.M., M.D.
Visiting Physician Lincoln Hospital.
NEW YORK.

During the past four years it has been my good fortune to witness the beneficial effect of certain climatic conditions on certain forms of circulatory disease. It has, indeed, been a surprise to myself, accustomed to city conditions, to see how much is accomplished by treatment of certain cases of secondary low arterial tension, even when accompanied by such accidents as hemiplegia, in the climate of the lower Maine coast.

My observations were made at York. The first case was one of secondary low arterial tension following high tension in a man who had had a prolonged and anxious business strain. While under this strain this man suddenly developed hemiplegia and aphasia. When I saw him he was suffering from these conditions. The heart was dilated; there were loud murmurs at the base and apex. He could not make any exertion without shortness of breath, and was extremely depressed. In other words, he was suffering from all signs of a marked deterioration of the circulatory apparatus. The improvement in this case was very marked, so that by the end of the summer the man was able to take long walks, his paralysis and aphasia were much improved, and a process was checked which had every indication of progressing to a fatal termination.

Another case was that of a woman, also suffering from right hemiplegia and slight aphasia, in whom the secondary low arterial tension was just commencing. She also made vast improvement by the end of the summer, and had even for the time being recovered from the tendency to high tension.

The third was a case of a woman with low arterial tension secondary to an exhausted nervous system and the high tension of nervous strain. She also improved very much, but, the cause not being removed, the improvement was not so marked.

Now, it may not seem that climate had much to do with these cases, but a study of the effect of the climate and an analysis of its characteristics make it evident that for this class of cases the summer climate of lower Maine coast is particularly beneficial. The climate of the lower Maine coast has a remarkable combination of dryness with sea air and low temperature in summer. It is beneficial in all cases of physical exhaustion and to patients who require a restoration of the vitality after disease. The climate is wonderfully stimulating to nutrition. On the other hand, it is not beneficial to patients suffering from purely functional nervous diseases requiring rest. These patients are overstimulated and are apt to suffer from restlessness and insomnia. Still, patients with a tendency to melancholia and depressed conditions are much improved. The physical effect of the transition from the climate of New York to the climate of the lower Maine coast is really remarkable. Those unaccustomed to the change find a longer stay than six weeks too stimulating. So that many persons who make their summer home there find it beneficial to go inland to a less exciting climate for a rest in the middle of the season.

We all know how difficult is the task of restoring what we call vitality. This is a word so frequently on the lips of physicians that I have noticed that when first used to a new client it often excites a smile on the part of the patient. One said the other day: "Please do not talk any more about that thing you call vitality." Whether we talk about it or not, it is an important element with most chronic invalids, and it is the element that has seemed to me most benefited by this particular climate. The drawback with most seashore climates is the great dampness. The lower Maine coast escapes the fogs which are so prevalent to the north and south. The ocean is very shallow and the shore recedes here so that the fog bank lays off the coast, within sight, but seldom reaches the land.

The Survival of the Fittest.—Modern medicine has been accused of helping to deteriorate the human race, by preserving the weaklings, and thus arresting the law of the survival of the fittest; but surely preventive medicine is enabling the nations that are intellectually fit, to survive, while those steeped in ignorance, are decimated by preventable diseases.—Hanbridge, in *Albany Med. Ann.*

A METHOD FOR THE RAPID PREPARATION OF FRESH TISSUES FOR THE MICROSCOPE.

LOUIS B. WILSON, M.D.
Pathologist St. Mary's Hospital.
ROCHESTER, MINN.

While engaged in general pathologic work I shared the common distrust of frozen sections of fresh tissues for microscopic diagnosis. On taking charge recently of the laboratories of the Drs. Mayo, surgeons, I carefully tested the various methods hitherto published and found them either too slow for results while the patient waits under the anesthetic or else giving poorly differentiated cell detail. After considerable experimentation the following technic was discovered, and for the last six months it has given uniformly excellent preparations:

1. Bits of fresh tissue not more than 2x10x10 mm. are frozen in dextrin solution and cut in sections of from 10 to 15 microns thick.

2. The sections are removed from the knife with the tip of the finger and allowed to thaw thereon.

3. The sections are unrolled with camel's-hair brushes in 1 per cent. NaCl solution.

4. The sections are stained from 10 to 20 seconds in neutral Unna's polychrome methylene blue.

5. They are washed out in 1 per cent. NaCl solution.

6. They are mounted in Brun's glucose medium.

The microtome which I use is the Spencer automatic with a CO_2 attachment in which vulcanite is substituted for brass in the wall of the freezing chamber, thus insulating the freezing plate. Thawing the section on the finger prevents to a great extent the formation of bubbles. The well-made camel's-hair brushes used by artists are much more useful for handling tissues than those usually furnished by laboratory supply houses. A heavy, shallow watch glass over a black surface is the best receptacle in which to unroll sections. Sections are best handled in the stain folded over a lifter made of a small glass rod drawn out and bent at convenient angle. The section is kept constantly moving while it is in the stain. The stain is contained in a minute cup to facilitate the rapid recovery of the section should it slip from the lifter. Washing out is done in several ounces of salt solution in a white porcelain dish and is continued only while the stain comes away freely. Brun's glucose medium (which is made by mixing distilled water 140 c.c., glucose 40 c.c., and glycerin 10 c.c., then adding camphorated spirit 10 c.c. and filtering), is held in an oval dish of porcelain (an "undecorated match safe") of such a size that a three-inch slide will rest in a slanting position, with one end in the bottom of the dish and the other on its edge. The section is spread out on the slide while it is in this position. The slide is then carefully withdrawn from the dish, the excess fluid removed, a cover-slip dropped over the section and the specimen is ready for the microscope.

The whole process can be gone through in one and a half minutes from the time the tissue is placed on the freezing plate of the microtome until the stained specimen is on the stage of the microscope. The resulting coloring is uniformly good with the tissue elements sharply contrasted in red, purple and dark blue.

A diagnosis may be made from such preparations in a large percentage of surgical cases in which a diagnosis is possible by a study of sections of the same thickness cut from fixed tissues and stained with hematoxylin and eosin.

FRACTURE OF BOTH CLAVICLES.

SCHUYLER W. HAMMOND, M.D.
RUTLAND, VT.

On Oct. 17, 1905, Mrs. H. W. H., aged 54, while running clothing from a second-story window out on an endless rope, was precipitated 15 feet below by the breaking of the rope.

Careful examination revealed fracture of the right clavicle at its outer angle and of the left clavicle at its middle. The patient also suffered separation of the os innominatum from the sacrum at the right sacroiliac synchondrosis, with some traumatism to the sacral plexus of nerves.

COUGHS AND COLDS.

The sudden changes in the weather during the period when fall is gradually passing into winter are likely to be the occasion for a number of ordinary colds. Because of the presence of these, it not infrequently happens that pulmonary affections of serious significance are thought to be no more than a simple cold. The cough, it is true, is likely to be much more persistent, but then, according to an old popular tradition, midseason coughs are supposed to be more liable to persist. It is easy to understand, then, how too little may be made of a cough, and, as a result, a patient may be allowed to lose precious time at the beginning of active pulmonary tuberculosis, each day of whose progress makes the ultimate prognosis a little less favorable. Tuberculous patients who continue their ordinary occupations are almost sure to have their symptoms gradually grow worse and their tuberculosis more active, and the possibility of an incipient case becoming fairly well advanced during the delay can be readily understood.

Those in charge of large sanatoria for the treatment of tuberculosis insist that the ordinary general practitioner does not recognize pulmonary tuberculosis soon enough for a cure to be possible in most cases in which the patients are sent away for sanatorium treatment. The physical signs and symptoms for which he waits before pronouncing the case certainly tuberculous are those of advanced and not of incipient tuberculosis. Dr. Trudeau, whose opinion in this matter is to be respected, said: "The average medical man's idea of tuberculosis only relates to the disease after the rational and physical signs have become well marked."

In a recent article, Dr. Willson[1] has collected the first subjective symptoms of 86 cases of tuberculosis that had been studied with special relation to the subject. As it is because of subjective symptoms that the patients present themselves for treatment, the importance of this method of viewing the question can be readily understood. In nearly all the cases, the first symptom noted was a persistent cough without a recognized cause. This often had its origin in what seemed to be an ordinary cold, and not infrequently disappeared after a time, only to be renewed on what seemed some trivial provocation. Usually in the intervals when there was no genuine cough, there was a frequent necessity of clearing the throat and a little hacking cough utterly unproductive and apparently due only to some irritation of the larynx was noted. It is these forms of unproductive cough for which there are so many and various names. We have all heard of a stomach cough, the gynecologists occasionally speak of the uterine cough, some have not hesitated even to use the term ovarian cough, there is a laryngeal cough, of course, a kidney and nervous cough, and then the ophthalmologists sometimes speak of a cough due to the lack of correction of some error of vision.

It seems clear that in most cases the use of these special designations for unproductive coughs that hang on is fraught with serious danger. In nearly all cases, a persistent cough is due to irritation of the lungs or of the larynx consequent on the presence of the tubercle bacillus. Long before there is any question of the presence of tubercle bacilli in the expectoration, this cough will manifest itself and will not disappear completely under any ordinary treatment that does not recognize the necessity for out-door air and constitutional upbuilding. The so-called stomach cough is especially deceptive, since not infrequently the presence of tuberculosis in the system is manifested very early by a disturbance of the digestive function.

It is clear, then, that far from its being advisable to make little of a persistent cough, it is our duty to emphasize the necessity for finding out exactly what is the cause of it. Not infrequently it will be comparatively easy to find some other symptoms or physical signs that will add to the suspicion of tuberculosis in the case. Sometimes there will be no more than a tendency to rapid pulse on very little exertion, or a slight rise of temperature or a temperature normal in the afternoon, but distinctly subnormal in the morning. If any of these symptoms are present then the suspicion is more than confirmed, and until the cough can be relieved the question of tuberculosis must be allowed to remain open. At times such patients will say that they have cold hands and feet, with a tendency to perspire rather freely, either after slight exertion or after becoming thoroughly warmed in bed. Indeed, it is rather surprising how many important details can sometimes be brought out by careful questioning in what at first seemed to be "only an ordinary cold."

It is better to be frank with tuberculous patients rather than to follow the old policy of euphemistically glossing over conditions in order to save the patient a shock. For those who have not tuberculosis, frankness will have no bad effect, even if it should not be quite justified, and if it leads them to improve their physical condition so as to remove the suspicions that have been aroused, it will surely do good. Our best phthisiologists insist that this policy would save many lives every year, which is indeed a consummation to be devoutly wished.

THE DIAGNOSIS AND TREATMENT OF RENAL TUBERCULOSIS.

In these days of indiscriminate surgery, when the advent of asepsis allows and encourages the use of the knife by those who are not prepared to use it, the thinking internist is in danger of taking too conservative a view as to the necessity of operative procedures in certain classes of cases. Among the conditions which stand on debatable ground so far as operative indications are concerned, renal tuberculosis must be mentioned. There are many who believe that this condition is essentially a medical problem, and that operative treatment is to be resorted to only as a last chance, and this view is held even by genitourinary surgeons of note. In a paper before the recent Congress on Tuberculosis, Albarran,[1] who has certainly earned the right to speak authoritatively on this subject, discusses the problem in a very lucid manner. The decision as to whether a given condition is to be considered in the province of the physician or of the surgeon depends on a variety of circumstances. In dealing with tuberculosis in paired organs, like the kidneys, the problem is simplified by the fact that one can be removed with relative impunity provided that the other be intact. The main questions to be answered, then, are these: How frequently are the kidneys unilaterally affected in this condition? What is the usual outcome in cases treated expectantly on purely medical lines? How does the mortality under surgical treatment compare with that under medical?

These questions are taken up seriatim by Albarran, and are answered by quotations from his own statistics and from those of other observers of experience. Unilateral involvement in renal tuberculosis is the rule rather than the exception, it occurs in at least 85 per cent. of the cases, and in the majority there is no serious involvement of other organs, a point of great importance. It is true that in most cases there are symptoms which would lead the inexperienced to believe that the bladder also is infected, but the use of the cystoscope has shown conclusively that, at any rate early in the disease, the bladder lesion is of an irritative character, and is not a true cystitis. Even when signs of early lung involvement are present, a not unusual complication, experience has shown that operative intervention is rather of benefit than otherwise. The history of these cases under medical treatment is far from encouraging. Spontaneous healing is known, but is rare, and when it occurs is always due to the blocking of the ureter by the inflammatory process, a condition which throws the affected kidney out of function just as effectively as surgical removal, but is less satisfactory than the latter procedure on account of the length of time it consumes and the fact that it still leaves in the body a latent focus of disease which at any time, even years after the ureteral blocking, may again become active and cause the death of the patient. In most cases the progress under medical treatment is a slow but a steady downhill progression. Tuberculosis of the bladder, with its long-drawn agony, is followed by ascending infection of the sound kidney, or generalization of the disease, and the patient dies a lingering and painful death. In competent hands, the removal of the kidney is in itself an operation with slight mortality. Albarran lost but 3 per cent. of his cases, and the combined mortality of the six operators who have reported the largest series of cases totals 7 per cent. This is certainly a vast improvement over the mortality under medical treatment.

As in other conditions in which surgical intervention is of aid, its value often depends, in part at least, on the early recognition of the disease. This means that the general practitioner must learn to recognize, or at any rate to suspect, the presence of this condition at an early date. The specialist has at its command methods of diagnosis which, of necessity, are not available to the average physician. Catheterization of the ureters, of which the genitourinary surgeon speaks so glibly, is an operation requiring a good deal of skill, a large amount of experience, expensive instruments, and an amount of time which the ordinary physician does not possess. Yet it is the procedure *par excellence* in the diagnosis of early kidney tuberculosis. The practitioner must rely on other and more common methods of observation, and Albarran briefly sketches what he considers the more important of these. The history of vesical irritation, with more or less pain on urination, and the passage of a pale, slightly cloudy urine, is of importance. If a definite cystitis is present, its occurrence without definite cause, its aggravation under local treatment, and the absence of the ordinary micro-organisms from the urine are all suspicious circumstances. Attacks of spontaneous hematuria should be looked at askance, especially if they are not modified with rest, are painless, or are at most accompanied by vague painful sensations in the region of the kidneys. Naturally an examination of the urine for tubercle bacilli is called for, and it is to be remembered that the fresher the specimen the better the chance of finding the bacilli. The finer methods of diagnosis must often be left to the specialist. Early diagnosis is the key to success.

BALANTIDIUM COLI.

The infusorium, *Balantidium coli,* as the cause of human intestinal infection, was described first by Malmsten of Stockholm in 1857. Since then, something like 117 cases have been recorded, according to the recent summary by Strong,[1] and there seems all reason to believe that this parasite may give rise to diarrhea, sometimes serious and often persistent. It is an oval-shaped, ciliated organism, from .07 to 0.1 mm. in length by from .05 to .07 mm. wide, capable of motion and of some change in form; reproduction may take place in three ways, viz., by division, the most frequent; by budding, and by conjugation. It may undergo encystation.

---

[1] Presse Médicale, 1905, No. 80. Abstract in The Journal on page 1526.

[1] Bulletin of Government Laboratories, Manila, No. 26, Dec. 1904.

Balantidium coli occurs with great frequency in the colon and cecum of the hog, which is regarded as its proper host, and in which it appears to be a harmless commensal. It is not known how human infection takes place; water, in which the organism may live for a long time, may be the means and perhaps also uncooked sausage meat and other forms of food.

The majority of the reported human cases are from Russia (51); in proportion to the population, a relatively large number of cases have been described in Sweden (30) and Finland (13). Only one case[2] is credited to North America, and this occurred in a German farmer in Iowa, engaged in hog raising and sausage making; the diagnosis was made in Germany, the patient having returned home for treatment for fatigue, weakness, and pain in the abdomen to the left and below the navel. He had no diarrhea, but the feces contained undigested food. Strong and Musgrave have described a fatal case from Manila.

In the 117 cases collected by Musgrave, diarrhea or dysentery existed in all but 2, the feces often containing mucus and blood. Colic, tenesmus, abdominal swelling, nausea and vomiting may occur. Only two of the cases were in children. Twenty-five per cent of the patients gave a history that pointed to infection from the hog. When the intestinal lesions are not far advanced and the strength of the patient permits it, continued local treatment may drive away the parasites. Quinin and other substances have been used in enemas with success in the hands of some observers, while others report failure.

Of 111 patients 32 (29 per cent.) recovered, 30 per cent. died, and in a number of these other diseases were present. There have been 32 autopsies on patients known to harbor *Balantidium coli* and to suffer from diarrhea and other symptoms, and in 28 there were ulcerations of the large intestine, but the type of ulcer does not appear distinctive. Parasites were found postmortem in 21 cases, and histologic studies were made in only 7. In Strong and Musgrave's case living parasites were found in all parts of the large intestine and in the lower 4 or 5 cm. of the ileum, and in this case, as well in Solojew's case, the parasites had invaded the coats and vessels of the large intestine. Polynuclear eosinophiles were numerous about the parasites. In an outbreak of dysentery among the orang-outangs in the New York Zoological Garden, Harlow Brooks demonstrated balantidia in the feces, as well as in the coats of the large bowel, which presented the same changes as in the recently studied human cases. In order that the parasites may be recognized in the tissues it is necessary to secure early postmortems, as dead parasites disintegrate quickly, so that they can not be recognized in the sections.

There are many points in connection with the pathogenesis of balantidium infection that require further study. Thus the question whether the balantidium by itself can penetrate the normal mucous membrane is still an open one. Furthermore, the meaning of the presence of the infusoria in the blood vessels of the intestine, now noted in several cases, raises some interesting problems. Strong's summary gives a good basis for further work along these lines.

SUICIDE PREVENTION.

The enterprising mayor of Cleveland, who has achieved a national reputation by his advanced ideas on sociologic matters, has appointed, it is said, an anti-suicide commission, that is, a body of experts who shall devise ways and means of preventing the despondent and destitute from self-destruction. Suicide is increasing and is becoming more than ever a matter for concern to the well-wishers of the race. Many suicides can undoubtedly be accounted for by mental aberration, either actual insanity or temporary morbid impulse. With the increase of insanity suicide would also naturally increase. It seems doubtful, however, that we can properly attribute the very notable increase of self-destruction to these causes alone. The too prevalent pessimistic tendencies of the present time are probably still more responsible. To a despondent and suffering individual who can see no prospect of betterment, suicide often appears to be a rational—though not at all a heroic or praiseworthy—procedure, and the impulse may easily overcome both the natural instinct of self-preservation, and the inherent fear of consequences in a future life. Purely ethical considerations alone will not prevent it, though they have their influence. While the actual pathologic causal factors above mentioned mainly interest us as medical men, we can not altogether overlook the social disease that we believe is the main cause of the growing evil of to-day.

POLITICAL INFLUENCE.

In the organization of modern society the currents and counter-currents of interest and prejudice are not always easy of determination. The profession of medicine should present to society active evidence of absolute solidarity on all questions affecting the public health. Of course, we are at times unable to agree on a line of conduct on some particular topic, but one of the great benefits of organization is the opportunity afforded to thrash out debatable points among ourselves and then to present to the world the digested result. Frequently it becomes necessary for the professional units to make their influence felt on some particular problem. In many cases all that the organization need do is to disseminate the facts, leaving to the individual the decision as to the part he will play, while in others it is necessary for the profession openly to declare itself. In the elections this year, so far as known, there was no instance of medical societies acting officially, but there is reason to believe that in several states medical men had a share in bringing about the election of independent and reform candidates. In Philadelphia the medical men were in the front in the fight against the boodlers. In Ohio it is reported that professional sentiment was so strongly crystallized that five thousand physicians voted and worked against Governor Herrick, who was a candidate for re-election. The one chief reason for this unanimity of sentiment was the matter of the management of the Ohio Hospital for Epileptics, concerning which our readers were at the time kept fully informed. The governor gave aid and comfort to the politicians who wanted the "rake-offs" on contracts, even after the medical profession had in various ways urged him to an opposite course. The affront he put on the profession, however explained, could have but one result. As a sequence of this election it is hoped that all the charitable institutions of the state will receive a thorough investigation, following which better conditions seem assured. Probably also the unselfish counsel of the profession will not again be so lightly estimated. The result in Ohio should be an encouragement for physicians in other states to make every legitimate effort to bring about reforms, when necessary, in the conduct of state institutions.

---

[2] Reported by Mitter, Inaug. Diss., Kiel, 1891.

THE NOSTRUM EVIL.[1]

When the program of the Section on Practice of Medicine for the Portland session announced that a paper was to be read on nostrums, the manufacturers and exploiters of these preparations became anxious. It was an innovation for one of the largest and most important sections to take up such a subject as this. The Section on Pharmacology and Therapeutics on several occasions had discussed the matter in a kind of a semiofficial way; but this was different. What did it mean? Stenographers were engaged to find out and to report the paper in full, so that something might be done if it were possible and necessary. Pretty soon something was done. Evidently the paper hurt, for Dr. Billings and The Journal began to receive letters, some of them from lawyers, threatening all kinds of trouble if the paper should be published. Since the paper seemed to be so dangerous to the nostrum men, it was thought that it ought to have a larger circulation than it would if published in this journal only, and the state society journals were asked to aid in the publicity movement. This, too, came to the knowledge of those especially interested, and at least one of them sent an intimidating letter to the editors of the journals which it was believed might publish the paper. We rather think that few of the editors were sufficiently intimidated to prevent them from carrying out their original intention Consequently, the paper on the nostrum evil will have about as wide circulation as any paper ever had. In this connection we wish to thank those journals which have expressed such grave anxiety lest we get into trouble by printing matter that would in any way injure the nostrum manufacturers. We realize that it is an awful thing to do, but it's done.

THE YELLOW-FEVER CONTROVERSY.

"Whose fault was it?" This is the question New Orleans is endeavoring to answer. We have already referred to Dr. Joseph Holt's charges against the health officials. These have been followed by a most extraordinary occurrence. The Mississippi State Board of Health, it is reported, has adopted a resolution expressing its hope that Louisiana will retire the president of its State Board of Health and the health officer of New Orleans, Dr. Souchon and Dr. Kohnke, respectively. Dr. Kohnke has published a very full reply to Dr. Holt and to the Mississippi officials, in which he shows conclusively that there are two sides to the question, and that impartial decision will hardly be possible until there has been thorough, unprejudiced investigation of the facts. He makes the telling point that, while it since has seemed probable that yellow fever existed in New Orleans since April or May, there was nothing to arouse suspicion. The first case was reported on July 12, and inspection and fumigation were at once begun. The early cases were very mild and were not recognized as yellow fever by the attending physicians. It should not be overlooked that the early cases of an epidemic of any infectious disease are frequently so atypical and mild that even the expert diagnostician is misled; and hence that the first cases pass unrecognized, though no one can be held at fault. Those who hold the other view contend that the cases were recognized, but were concealed. Here is where nothing but knowledge of the facts can quiet the controversy or afford the outsider any opportunity for reaching conclusions. Until such knowledge is available, physicians will prefer to believe that mild unsuspected cases of yellow fever were unrecognized rather than that undoubted cases were deliberately concealed. Certainly, all will hope that such will prove to be the case. The chief count in the indictment against Dr. Souchon and Dr. Kohnke is that they gave no warning of the danger until after July 19, a date on which all the railroads ran cheap popular excursions into New Orleans from Mississippi, Louisiana, Alabama and Florida. It has been declared that this excursion was the chief factor in the wide simultaneous dissemination of the infection. At present one conclusion has emerged from the controversy—the old one that every city needs a stringently enforced and effective ordinance compelling physicians to report all infections. Without effective notification ordinances, heartily supported by professional opinion and action, similar calamities will from time to time recur.

The Profession's Future.—President Faunce of Brown University, addressing the Rhode Island Medical Society, said that the medical profession will advance in the next twenty-five years in toleration and breadth of horizon. "Not only intensively will the profession advance in mastery of its present instruments and methods, but extensively as well it must progress in fashioning new instruments, in recognizing new methods, and exercising genuine intellectual hospitality. A hospitable mind is the peculiar product of the scientific era. In the prescientific age, hospitality was a sign of weakness and source of danger. . . . We now see that intolerance is the child of uncertainty. The man who is not sure of his position is afraid to meet the men who differ from him; the man who is quite certain of his own established faith is glad to listen to voices that speak from any quarter of the horizon."

---

[1] The word "secret" in the title of Dr. Billings' paper—see first article in this issue—was marked to be omitted, but through an oversight this was not done.

pitals of Kansas City, Mo., have opened their doors to the students.——A free eye clinic has been opened by the college at the German Hospital, Kansas City, Mo.

Diphtheria.—The public school at Stone City has been closed on account of diphtheria.——During October, four deaths resulted from diphtheria and 60 cases were reported in Leavenworth.——The public schools in Abilene have been closed on account of diphtheria.——The public schools at Arkansas City have been closed indefinitely in the hope of preventing an epidemic of diphtheria.——More than 50 cases of diphtheria are under treatment at Moline.——The schools at Mound Valley have been closed on account of an epidemic of diphtheria.

MARYLAND.

Personal.—Dr. Richard C. Harley has resigned as health officer of Laurel.——Dr. John Mace, Cambridge, has been appointed lieutenant in the Maryland Naval Reserves and assigned to duty with the Cambridge division.——Dr. James M. Spear, Cumberland, has been appointed local surgeon for the Western Maryland Railroad.——Dr. Washington G. Tuck, Annapolis, has resigned the chairmanship of the Republican state central committee.——Dr. John E. Bolte, Harrisonville, resigned as sanitary physician for the second district of Baltimore County November 21, and Dr. Harry F. Shipley has been appointed in his place.——Dr. John W. Lacy, Lisbon, returned from Europe on the *Oceanic*, arriving in New York October 25.

Baltimore.

A Poor Response.—In answer to the appeal for $6,000 by the Maryland Association for the Prevention and Relief of Tuberculosis for a year's campaign against the "white death". $627 have been received to date.

Matriculants.—The number of matriculants in the University of Maryland School of Medicine for the present session is 331, not 99 as erroneously stated in The Journal last week. ——At the Johns Hopkins University there is a total enrollment of 293 in the medical department.

Died in Prison.—Mrs. Emma O. Lewis, who was sentenced on June 30 to three years' imprisonment in the state penitentiary for performing a criminal operation and for whose pardon a petition was being circulated, died in the penitentiary October 25 from the results of despondency.

Vital Statistics.—The number of deaths for the week ended November 25 was 220, a number larger than for the same period for several years, the annual death rate represented being 19.95 per 1,000. The chief causes of death were: Consumption, 30; pneumonia, 29; Bright's disease and organic heart disease, each 19; bronchitis, 9, and typhoid fever, 8. There were 2 deaths attributed to grippe and only 2 to cancer.

Home from Europe.—Dr. and Mrs. William Green have returned from Europe.——Dr. and Mrs. T. Caspar Gilchrist have returned after a summer in Europe.——Dr. William H. Welch, who spent the summer abroad, has returned.——Dr. William Whitridge has returned from Europe.——Dr. John M. T. Finney, surgeon general of the state, has returned after a summer in Europe.——Dr. and Mrs. Maurice Bloomfield have returned after a summer abroad.

Personal.—Health Commissioner Bosley has announced the following appointments: Medical inspectors of public schools (reappointed), Drs. Isham R. Page, J. Hal Pleasants, (new appointments), Drs. J. Howard Iglehart, A. Duvall Atkinson and W. H. Clendenin Teal. The appointments take effect December 1, the salaries being about $900 per annum.——Dr. Eugene F. Cordell read a paper by invitation before the historical section of the College of Physicians of Philadelphia, November 29, on "Joseph Roby, the Anatomist."——Dr. G. R. Holden has resigned as resident gynecologist at Johns Hopkins Hospital and Dr. Stephen Rushjore has been elected in his place. Dr. H. M. Little, resident obstetrician at the same institution, has resigned and Dr. F. C. Goldsborough has been elected his successor.——Dr. Fannie E. Hoopes sailed for Europe early this month.——Dr. Robert T. Wilson has been elected president of the Hospital Relief Association of Maryland.

Dr. Hemmeter Honored.—A number of prominent physicians met in the home of Dr. John C. Hemmeter, November 15, and presented him with a handsome oil painting of himself in commemoration of the twentieth anniversary of his doctorate. Supervising Surgeon-General Walter Wyman, United States Public Health and Marine-hospital Service, in behalf of the ninety-five subscribers, made the address of presentation, in which he stated that Dr. Hemmeter had demonstrated in his life the great truth that a man may be a great physician and yet eminent in other walks of life, cultivating to a high degree a love of the beautiful and good as well as the true, and that in appreciation of intellect and broad manhood alike, his friends had been prompted to present to him this testimonial. Drs. Thomas A. Ashby and Charles G. Hill also spoke in praise of Dr. Hemmeter and of his work. In Dr. Hemmeter's reply he made an appeal for idealism in medicine because of his conviction, as he expressed it, that:

> The sphere of action of the medical man is threatening to become too narrow and disregard for high ideals in medicine has led to the temptation of too narrow an exclusiveness for the applied feature of this art of science; a disregard for ideals can not fail to develop commercialism in medicine, a vice already strongly raising its head through the multiplicity of medical schools in this country.

Dr. Hemmeter further said:

> Scholars and practitioners in medicine have been keenly alive to law and knowledge and material fact, but they have been occasionally blind to art, to poetry, to emotion, to the philosophy of the classics and to the higher mental and spiritual environment which inspires and glorifies the realms of their magnificent science.
>
> One of my cherished wishes is for the reduction of the number of medical schools by consolidation of three of the leading institutions. Those of us who have the conduct of these schools as part of our duties should not be hopeless of attaining this end. for reason and the collective wisdom of our representative medical colleagues should soon find some effective means of bearing down those obstacles, which individual shortsightedness, selfishness and passion oppose to all improvements and by which the highest hopes are continually blighted and the fairest prospects marred.

After the presentation those present were entertained at a luncheon supper by Dr. and Mrs. Hemmeter.

NEW JERSEY.

Personal.—Dr. John P. Henry, Jersey City, has resigned as a member of the board of health.——Dr. Edward J. Ill, Newark, who was operated on November 12, is convalescing.

Medical Examinations Inaugurated.—The Atlantic City Medical Examining Board began its work in the public schools October 22, under the direction of the city health officer, Dr. Edward Guion.

Medical Library Association.—Physicians of Newark are putting into working shape the plans for the medical library association which was organized November 18. The librarian of the Newark Public Library announces that there will be no abridgment of the rights or privileges of the public, and that while the Medical Library Association will be a distinct organization, the books purchased by it will be free for the use of the general public. He states that so far as the library is concerned the new association will merely be a medical department of the institution. The association has adopted a constitution providing for an initiation fee of $3 and dues of $3 per year. Dr. Charles J. Kipp was elected president; Dr. Henry L. Coit, vice-president, and Dr. Frank W. Pinneo, secretary and treasurer.

NEW YORK.

Epidemic Diseases.—Scarlet fever is prevalent among the pupils at the Robinson street school, Binghamton.——The South street school, Utica, has been ordered closed on account of scarlet fever and diphtheria.

Utica Has New Hospital.—The new St. Luke's Hospital, Utica, the gift of Mr. and Mrs. Frederick F. Proctor, has been handed over to the board of trustees, paid for and completely furnished with modern medical and surgical appliances.

Personal.—Mayor-elect Adams has appointed Dr. Ernest Wende, who was for eight years health commissioner of Buffalo, health commissioner, to take effect Jan. 1, 1906. Dr. Francis E. Franczak was appointed assistant health commissioner.——Dr. and Mrs. Daniel B. Hardenbergh, Middletown, reached New York from Liverpool on the Baltic, Nov. 10.——Dr. Alfred Mercer, Syracuse, celebrated his eighty-fifth birthday anniversary Nov. 14.

Hospital News.—The German Hospital fair, at Buffalo, is believed to have netted about $15,000 for the institution.——Ellis Hospital, Schenectady, received $2,531.30 as the annual contribution from the churches of the city.——The Binghamton State Hospital asks for an appropriation for improvements amounting to $125,000. This includes the erection of a hospital building for acute cases.——The W. C. A. Hospital, Jamestown, has been bequeathed $1,000 by the will of the late Fred A. Bentley.——The dedicatory exercises of the Little Falls Hospital occurred Nov. 13 in the new hospital building.

Medical News

ILLINOIS.

Will Have Wisconsin Society for Guest.—The Winnebago County Medical Society at its meeting in Rockford, Jan. 9, 1906, will entertain the Central Wisconsin Medical Society. It is expected that more than fifty physicians from Wisconsin will be present.

Change in Classification.—The state civil service commission on November 22 rescinded its recent action dividing the classified service into seven branches and enacted a new rule embodying ten classes of employes. Under the medical service the following are included: Assistant physicians in insane hospitals, physicians, surgeons, pathologists, oculists, pharmacists, apothecaries and druggists.

Diphtheria.—A number of cases are reported in Moline.——The secretary of the State Board of Health has announced that promiscuous use of slate and lead pencils in public schools is responsible for the spread of contagious diseases, with especial reference to diphtheria.——Diphtheria is prevalent at Metcalf and the schools and outbuildings have been thoroughly disinfected.——There is said to be much diphtheria in Granville and Ladd, but the epidemic in Spring Valley is now declared to be under control.

Tent Colony to be Dedicated.—The Ottawa tent colony, which was established a little more than a year ago, to demonstrate the possibility of cure of tuberculosis in this climate, has been quite successful, as was anticipated. Extensive improvements have been made to meet the increased demand and to make the treatment more attractive. To increase the educational value of this colony the dedicatory exercises will be held at Ottawa December 12. The program will include short addresses by physicians and laymen. Excursion rates will be in force from all points in Illinois.

Per Capita Cost at State Institutions.—The report of the Illinois Commissioners of Public Charities for the quarter ended September 30 gives the following as the per capita cost of the various state institutions: Illinois Western Hospital for the Insane, Watertown, $26.21; Illinois Eastern Hospital for the Insane, Hospital, $30.05; Illinois Hospital for the Incurable Insane, South Bartonville, $30.32; Illinois Central Hospital for the Insane, Jacksonville, $31.27; Illinois Southern Hospital for the Insane, Anna, $35.13; Illinois and Northern Hospital for the Insane, Elgin, $38.67, and Illinois Asylum for Insane Criminals, Menard, $50.43.

Evanston Hospital.—At the annual meeting of the Evanston Hospital Association, November 14, the president began his report by quoting the notice which appears on the gate of the London Hospital: "The passport for admission is sickness or injury combined with poverty. No letters required." The records of the Evanston Hospital show that during the fiscal year 85 free patients were admitted, or more than 25 per cent. of the total number of patients received during the year. In the children's ward 22 patients were admitted, 14 of whom were free patients. The total number of days' service during the year was 7,561, or 622 days more than last year.

Society Indorses New Army Medical Bill.—The Adams County Medical Society, at its meeting November 13, adopted the following resolution, which concluded with an indorsement of the bill to increase the efficiency of the Medical Department of the United States Army as drawn up by the surgeon general of the Army and approved by the President:

> Whereas, Seven years have elapsed since the country was shocked by the disgraceful sanitary conditions which prevailed at Chickamauga, Jacksonville and Camp Alger during the Spanish War, and yet no successful effort has been made to remedy the inadequacy and faulty organization of the medical department of the United States Army to which this utter failure of military sanitation was chargeable, and,
>
> Whereas, The continuance of these discouraging conditions is depleting the army medical service of its best men by resignation, and deterring the brightest minds of the profession from seeking a future in so promising a field, therefore,
>
> *Resolved*, That in the judgment of this society the situation is so critical as to demand immediate measures for relief.

Chicago.

Personal.—Dr. Albert Goldspohn has donated $25,000 for the erection of a science hall at the Northwestern College, Naperville.

Hospital Permit.—A building permit was issued November 22 for the Chicago Policlinic to erect a six-story brick hospital at 319 to 331 La Salle Avenue.

Sale of Dangerous Drugs Prohibited.—The city council at its meeting November 20 passed the amendment to the ordinance prohibiting the sale of morphin and similar drugs, so that they can be obtained only on the prescriptions of physicians or dentists.

Hospital Dedicated.—The St. Bernard's Hotel Dieu in Englewood was dedicated with impressive ceremony November 21 by Archbishop Quigley. The building is five stories high, as nearly fireproof as modern science can make it, and will accommodate 280 patients.

Expenditures for the Poor.—At the forty-eighth annual meeting of the Chicago Relief and Aid Society, held November 13, the president reported that the society had spent $26,400 in the direct relief of the poor during the fiscal year. A new feature of the work was the fresh air station for sick babies and the visiting nurse association. The society now controls 160 hospital beds.

Secures One Dollar Verdict.—In Judge Gary's court November 17 a jury awarded Mrs. J. Jessen one dollar damages from Dr. Henry J. Burwash, whom she had sued, together with the Hospital of St. Mary of Nazareth, for $10,000 damages, alleging that an unnecessary operation had taken place resulting in the death of her son two years ago, and that the body of her son had been mutilated.

Deaths of the Week.—The total deaths from all causes for the week ended November 25 were 471, equivalent to an annual death rate of 12.34 per 1,000. The number of deaths is 39 less than for the preceding week, and 46 more than for the corresponding week of 1904. Pneumonia continues to lead the death causes with 73, followed by consumption, with 60; nephritis, with 49; heart diseases, with 42; violence, including suicide, with 30; acute intestinal diseases, with 25, and cancer, with 20.

IOWA.

Do Not Wish Names Mentioned.—At a recent meeting of the Scott County Medical Society resolutions were adopted to the effect that the editorial departments of the various papers be requested not to mention the names of physicians in connection with medical services, operations or accidents.

Hospital Notes.—St. Joseph's Mercy Hospital, Webster City, was dedicated and opened November 16.——Mrs. E. Tillotson, Highlands, N. J., has given $1,000 to the Ottumwa Hospital Association in memory of her father, the late Dr. William M. Murdock of Urbana, Ohio.——Dr. William H. Corrigan is about to open an emergency hospital in Rockwell.

Personal.—Dr. Frank W. Smith and family, Red Oak, returned October 29 from a trip to the Pacific Coast.——Dr. Cassius C. Cottle and family, Marshalltown, will spend the winter in southern California.——Dr. Thomas E. Livingston Bode expects to spend the winter in California.——Dr. E. R. Wallizer, Des Moines, has been committed to the Clarinda State Hospital.

Illegal Practitioner Found Guilty.—J. C. Wilhite, Fort Dodge, a so-called "doctor of neurology," was found guilty November 18 of the illegal practice of medicine. The defendant admitted that he did not attempt to treat diseases, but that he had advised patients how to treat themselves. Notice of appeal to the supreme court was filed. The heaviest penalty possible is a fine of $3,000.

Epidemic Diseases.—The Board of Health of Dubuque has ordered all the schools and churches of that city to be fumigated because of an epidemic of typhoid fever.——Since October 1 more than sixty homes in Sioux City have been placed in quarantine on account of diphtheria and scarlet fever.——A large number of cases of typhoid fever have developed in and around Ames in the last few weeks.——A mild epidemic of diphtheria and scarlet fever exists in Waterloo.——Typhoid fever has assumed alarming proportions in Estherville.——An epidemic of typhoid fever exists in the Iowa Institution for the Feeble-minded, Glenwood.

KANSAS.

Loss by Fire.—The office of Dr. Silas A. Boam, Topeka, was destroyed by fire, supposed to be of incendiary origin, October 23.

Personal.—Dr. Ambrose Weber has purchased the practice of Dr. D. H. Horner, Perth.——Dr. William C. Bower, Lebanon, has been appointed local surgeon for the Rock Island Railway system.

Kansas University.—The contract for the hospital building for the State University Medical School, Rosedale, has been let. The estimated expense of the building will be $100,000.——The clinical department of the school, located in Kansas City, Kan., is now in good working order and the hospitals of Kansas City, Mo., have opened their doors to the students.——A free eye clinic has been opened by the college at the German Hospital, Kansas City, Mo.

Diphtheria.—The public school at Stone City has been closed on account of diphtheria.——During October, four deaths resulted from diphtheria and 60 cases were reported in Leavenworth.——The public schools in Abilene have been closed on account of diphtheria.——The public schools at Arkansas City have been closed indefinitely in the hope of preventing an epidemic of diphtheria.——More than 50 cases of diphtheria are under treatment at Moline.——The schools at Mound Valley have been closed on account of an epidemic of diphtheria.

MARYLAND.

Personal.—Dr. Richard C. Harley has resigned as health officer of Laurel.——Dr. John Mace, Cambridge, has been appointed lieutenant in the Maryland Naval Reserves and assigned to duty with the Cambridge division.——Dr. James M. Spear, Cumberland, has been appointed local surgeon for the Western Maryland Railroad.——Dr. Washington G. Tuck, Annapolis, has resigned the chairmanship of the Republican state central committee.——Dr. John E. Bolte, Harrisonville, resigned as sanitary physician for the second district of Baltimore County November 21, and Dr. Harry F. Shipley has been appointed in his place.——Dr. John W. Lacy, Lisbon, returned from Europe on the *Oceanic,* arriving in New York October 25.

Baltimore.

A Poor Response.—In answer to the appeal for $6,000 by the Maryland Association for the Prevention and Relief of Tuberculosis for a year's campaign against the "white death", $627 have been received to date.

Matriculants.—The number of matriculants in the University of Maryland School of Medicine for the present session is 331, not 99 as erroneously stated in The Journal last week. ——At the Johns Hopkins University there is a total enrollment of 293 in the medical department.

Died in Prison.—Mrs. Emma O. Lewis, who was sentenced on June 30 to three years' imprisonment in the state penitentiary for performing a criminal operation and for whose pardon a petition was being circulated, died in the penitentiary October 25 from the results of despondency.

Vital Statistics.—The number of deaths for the week ended November 25 was 220, a number larger than for the same period for several years, the annual death rate represented being 19.95 per 1,000. The chief causes of death were: Consumption, 30; pneumonia, 29; Bright's disease and organic heart disease, each 19; bronchitis, 9, and typhoid fever, 8. There were 2 deaths attributed to grippe and only 2 to cancer.

Home from Europe.—Dr. and Mrs. William Green have returned from Europe.——Dr. and Mrs. T. Caspar Gilchrist have returned after a summer in Europe.——Dr. William H. Welch, who spent the summer abroad, has returned.——Dr. William Whitridge has returned from Europe.——Dr. John M. T. Finney, surgeon general of the state, has returned after a summer in Europe.——Dr. and Mrs. Maurice Bloomfield have returned after a summer abroad.

Personal.—Health Commissioner Bosley has announced the following appointments: Medical inspectors of public schools (reappointed), Drs. Isham R. Page, J. Hal Pleasants, (new appointments), Drs. J. Howard Iglehart, A. Duvall Atkinson and W. H. Clendenin Teal. The appointments take effect December 1, the salaries being about $900 per annum.——Dr. Eugene F. Cordell read a paper by invitation before the historical section of the College of Physicians of Philadelphia, November 29, on "Joseph Roby, the Anatomist."——Dr. G. R. Holden has resigned as resident gynecologist at Johns Hopkins Hospital and Dr. Stephen Rushjore has been elected in his place. Dr. H. M. Little, resident obstetrician at the same institution, has resigned and Dr. F. C. Goldsborough has been elected his successor.——Dr. Fannie E. Hoopes sailed for Europe early this month.——Dr. Robert T. Wilson has been elected president of the Hospital Relief Association of Maryland.

Dr. Hemmeter Honored.—A number of prominent physicians met in the home of Dr. John C. Hemmeter, November 15, and presented him with a handsome oil painting of himself in commemoration of the twentieth anniversary of his doctorate. Supervising Surgeon-General Walter Wyman, United States Public Health and Marine-hospital Service, in behalf of the ninety-five subscribers, made the address of presentation, in which he stated that Dr. Hemmeter had demonstrated in his life the great truth that a man may be a great physician and yet eminent in other walks of life, cultivating to a high degree a love of the beautiful and good as well as the true, and that in appreciation of intellect and broad manhood alike, his friends had been prompted to present to him this testimonial. Drs. Thomas A. Ashby and Charles G. Hill also spoke in praise of Dr. Hemmeter and of his work. In Dr. Hemmeter's reply he made an appeal for idealism in medicine because of his conviction, as he expressed it, that:

> The sphere of action of the medical man is threatening to become too narrow and disregard for high ideals in medicine has led to the temptation of too narrow an exclusiveness for the applied feature of this art of science; a disregard for ideals can not fail to develop commercialism in medicine, a vice already strongly raising its head through the multiplicity of medical schools in this country.

Dr. Hemmeter further said:

> Scholars and practitioners in medicine have been keenly alive to law and knowledge and material fact, but they have been occasionally blind to art, to poetry, to emotion, to the philosophy of the classics and to the higher mental and spiritual environment which inspires and glorifies the realms of their magnificent science.
>
> One of my cherished wishes is for the reduction of the number of medical schools by consolidation of three of the leading institutions. Those of us who have the conduct of these schools as part of our duties should not be hopeless of attaining this end, for reason and the collective wisdom of our representative medical colleagues should soon find some effective means of bearing down those obstacles, which individual shortsightedness, selfishness and passion oppose to all improvements and by which the highest hopes are continually blighted and the fairest prospects marred.

After the presentation those present were entertained at a luncheon supper by Dr. and Mrs. Hemmeter.

NEW JERSEY.

Personal.—Dr. John P. Henry, Jersey City, has resigned as a member of the board of health.——Dr. Edward J. Ill, Newark, who was operated on November 12, is convalescing.

Medical Examinations Inaugurated.—The Atlantic City Medical Examining Board began its work in the public schools October 22, under the direction of the city health officer, Dr. Edward Guion.

Medical Library Association.—Physicians of Newark are putting into working shape the plans for the medical library association which was organized November 18. The librarian of the Newark Public Library announces that there will be no abridgment of the rights or privileges of the public, and that while the Medical Library Association will be a distinct organization, the books purchased by it will be free for the use of the general public. He states that so far as the library is concerned the new association will merely be a medical department of the institution. The association has adopted a constitution providing for an initiation fee of $3 and dues of $3 per year. Dr. Charles J. Kipp was elected president; Dr. Henry L. Coit, vice-president, and Dr. Frank W. Pinneo, secretary and treasurer.

NEW YORK.

Epidemic Diseases.—Scarlet fever is prevalent among the pupils at the Robinson street school, Binghamton.——The South street school, Utica, has been ordered closed on account of scarlet fever and diphtheria.

Utica Has New Hospital.—The new St. Luke's Hospital, Utica, the gift of Mr. and Mrs. Frederick F. Proctor, has been handed over to the board of trustees, paid for and completely furnished with modern medical and surgical appliances.

Personal.—Mayor-elect Adams has appointed Dr. Ernest Wende, who was for eight years health commissioner of Buffalo, health commissioner, to take effect Jan. 1, 1906. Dr. Francis E. Franczak was appointed assistant health commissioner.——Dr. and Mrs. Daniel B. Hardenbergh, Middletown, reached New York from Liverpool on the Baltic, Nov. 10.——Dr. Alfred Mercer, Syracuse, celebrated his eighty-fifth birthday anniversary Nov. 14.

Hospital News.—The German Hospital fair, at Buffalo, is believed to have netted about $15,000 for the institution.——Ellis Hospital, Schenectady, received $2,531.30 as the annual contribution from the churches of the city.——The Binghamton State Hospital asks for an appropriation for improvements amounting to $125,000. This includes the erection of a hospital building for acute cases.——The W. C. A. Hospital, Jamestown, has been bequeathed $1,000 by the will of the late Fred A. Bentley.——The dedicatory exercises of the Little Falls Hospital occurred Nov. 13 in the new hospital building.

New York City.

Same Death-Rate.—The death-rate for the week ended November 18 was exactly the same as in the corresponding week of 1904, namely, 16.48 per 1,000. Cold weather increased the number of deaths from pneumonia.

Pure Food Legislation.—The New York section of the Council of Jewish Women held a mass meeting in support of pure food, December 2, at Mendelssohn Hall, at which United States Senators W. B. Heyburn and P. J. McCumber, Dr. Harvey W. Wiley, chief of the Bureau of Chemistry, Department of Agriculture, and others, delivered addresses.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 18, 419 cases of tuberculosis, with 174 deaths; 286 cases of diphtheria, with 17 deaths; 253 cases of measles, with 6 deaths; 132 cases of scarlet fever, with 4 deaths; 84 cases of typhoid fever, with 16 deaths; 10 cases of cerebrospinal meningitis, with 9 deaths, and 137 cases of varicella.

Personal.—A reception to Dr. Suzuki, surgeon-general of the Imperial Japanese navy, was given in the Farmington rooms of the New York Exchange for Women's Work, November 24.——Dr. E. C. Podvin has been elected a member of the staff of the new Philanthropic Hospital at Williamsbridge.——Dr. Robert F. McDonald has been elected a member of the Board of Coroners of the Bronx.——Dr. G. A. Hare has gone to Fresno, Cal.

For New Jewish Hospital.—A large fair for the benefit of this institution was opened on November 27. The entire cost of the hospital was $311,000, and there is still a shortage of $111,000. It will cost $100,000 a year to run the hospital at its full capacity of 175 beds. Six thousand dollars has already been contributed toward an endowment fund. During the past year there have been 20,767 persons treated at the dispensary connected with this hospital.

To Admit Non-Sectarians.—A resolution has been formulated by members of the Medical Society of the County of Kings looking to the admission of others than those connected with the so-called regular school. It considers the advisability of admitting to membership graduates of eclectic and homeopathic schools who agree to practice non-sectarian medicine. It is announced that a board of censors will see to it that any man admitted to the society shall be morally and medically fit.

OHIO.

District Society Meeting.—The second annual meeting of the First Councilor District Medical Society was held in Cincinnati November 17. Dr. John C. Larkin, Hillsboro, was elected president; Dr. Robert Carothers, Cincinnati, secretary, and Dr. Walter E. Murphy, Cincinnati, treasurer.

Hospital Dedicated.—The Memorial Hospital, Piqua, was formally dedicated November 30. Drs. Asa S. Ashton, Kesley W. Beauchamp, Francis M. Hunt, Ramsey L. Hyde, Robert L. Kunkle, Ada L. Malick, Levi E. Reck, Parker L. Snorf, Lloyd D. Trowbridge, William N. Unkefer and H. H. Gravitt made up the reception committee.

Personal.—Dr. Charles Biers, Painter Creek, has gone to Jacksonville, Fla., for his health.——Dr. Alexander M. Steinfeldt, Columbus, who is studying in Vienna, has been appointed voluntary assistant in the ambulatorium of Dr. Lorenz.——Dr. George H. Wilson has been appointed local surgeon of the Baltimore & Ohio Railroad at Painesville.——Dr. Orville A. Rhodes, Salem, has started for the Pacific Coast.

PENNSYLVANIA.

Married Many Years.—Dr. and Mrs. Philip S. P. Walter, Nazareth, celebrated their golden wedding anniversary November 6.

Epidemics.—Diphtheria is said to be epidemic at McKinley.——Four deaths have occurred from diphtheria in Hamburg.——Measles is reported to be epidemic in the Soho district of Pittsburg.

Practiced Without License.—Dr. H. O. Sampsel, Scottdale, convicted November 19 of practicing medicine without a license, was sentenced to pay a fine of $50 and costs. On account of the prisoner's inability to pay he was committed to jail.

The Vaccination Question.—The Department of Health dismissed 511 unvaccinated pupils from the public schools of Chambersburg November 1.——The Pottsville Board of Health has barred out 300 pupils from the public schools because of lack of vaccination.——At Selinsgrove 60 children were dismissed from the public schools November 13 on account of not having vaccination certificates.——Because she refused to allow her son to be vaccinated, according to the provision of the compulsory school law, Mrs. Victoria Moulton, East Lemon, has been twice imprisoned by order of court, the first time for two days and the second for five.

Personal.—Dr. Charles Rae, York, fractured one of the small bones of his foot while exercising at a gymnasium November 3.——Dr. George H. Halberstadt, Third Brigade, N. G. Pa., while returning from Philadelphia to his home in Pottsville, was struck on the head by a large stone which was thrown through the window of a car in which he was seated. He was rendered unconscious and a deep gash was inflicted.——Dr. William R. Brothers, Tamaqua, has been placed in charge of a new medical examiner's district of the Reading Railway System at Harrisburg.——Dr. Oliver L. Blachly, Wilkinsburg, and family, have gone to Pasadena, Cal.——Dr. Henry W. Saul, Kutztown, has been appointed physician to the Keystone State Normal School in that place.

Hospital News.—The medical staff of the Chester Hospital held a meeting November 11 and reorganized, re-electing Dr. Jonathan L. Forwood president of the staff and Dr. Leon Gottschalk, secretary. Dr. Forwood was also made chief of the surgical staff, which comprises Drs. F. Farwell Long, Samuel R. Crothers, Lewis H. Crothers and Leon Gottschalk. Dr. Daniel W. Jefferies was chosen chief of the medical staff, which includes Drs. Ellen E. Brown, Katherine W. Ulrich, Edward W. Bing and Frederick H. Evans.——The directors of the Chambersburg Hospital have elected the following staff: Dr. Charles F. Palmer, Henry X. Bonebrake, Robert W. Ramsey, David Maclay, W. Frank Skinner, Henry C. Devilbiss, John C. Greenewalt, P. Brough Montgomery, L. Federick Suesseprott, Johnston McLanahan and John P. Seibert.

Communicable Diseases Designated.—The state commissioner of health has sent a circular letter of instructions to every physician in the state, calling attention to the regulation of the department of health requiring a report of all contagious diseases to the secretary of the board of health of the city or borough in which the case occurs. The following is the list of diseases: Actinomycosis, anthrax, bubonic plague, cerebrospinal meningitis, chickenpox, cholera, diphtheria, epidemic dysentery, erysipelas, German measles, glanders, hydrophobia, leprosy, malarial fever, measles, pneumonia, puerperal fever, relapsing fever, scarlet fever, smallpox, tetanus, trachoma, trichiniasis, tuberculosis, typhoid fever, typhus fever, whooping cough and yellow fever. The so-called "membranous croup," "diphtheritic croup," or "putrid sore throat," is to be reported as diphtheria, and the so-called "scarlatina" and "the scarlet rash" as scarlet fever. The department of health will furnish blank notices for reporting contagious diseases, and the state pays for the postage on these notices.

Philadelphia.

Martin's Successor.—On November 27 Dr. William M. Late Coplin, professor of pathology and bacteriology, Jefferson Medical College, and director of the Jefferson Hospital laboratories, was appointed by Mayor Weaver, director of health and charities of Philadelphia, vice Dr. Edward Martin resigned. Dr. Coplin served as a member of the commission to organize the bureau of bacteriology, and later as a member of the Civil Service Commission. During the cholera epidemic in 1892 he was appointed an officer in the United States Marine-Hospital Service and acted as inspector of immigrants. At this time he established an emergency service in large industrial establishments where cases of communicable disease, heat stroke, etc., might be early diagnosed and promptly treated. He was bacteriologist to the State Board of Health, and is at present a member of the non-partisan commission to formulate laws to govern the disposal of tuberculous animals. He is a member of the American Medical Association, American Public Health Association, all the more important medical societies, and is president of the Philadelphia Pathological Society. He has served on the staffs of four hospitals and has held chairs in three medical colleges. His contributions to medical literature have been many and varied. His "Manual of Pathology" has reached a fourth edition, and a second edition of his "Manual of Practical Hygiene" is in process of preparation.

TENNESSEE.

College Opens.—The seventeenth annual session of the Tennessee Medical College, Knoxville, opened November 1. The Lincoln Memorial Hospital, in connection with the college, will be ready to receive patients early in December.

Commencement.—The commencement exercises of the Medical Department of the University of the South, Sewanee, were held October 26. Dr. Hampton L. Fancher, Orme, delivered the charge to the graduating class, which consisted of 27 members.

New College.—Drs. Heber Jones, J. C. Elliot, J. A. Crisler and Maximilian Goltman made applications for a charter November 15 for the College of Physicians and Surgeons of Memphis. The capital stock of the corporation is fixed at $40,000. The building is planned to cost not less than $60,000.

Middle Tennessee Physicians Meet.—The Middle Tennessee Medical Association held its annual session in Lebanon November 17-18, and elected the following officers: Dr. Charles N. Cowden, Fayetteville, president; Dr. Lynn B. Graddy, Nashville, vice-president, and Dr. William Litterer, Nashville, secretary and treasurer.

Personal.—Dr. Heber Jones, president of the Memphis Board of Health, has been presented with a purse of $10,000 in appreciation of his successful efforts in maintaining a prohibitive quarantine during the recent epidemic of yellow fever in the South.——Dr. Philander D. Sims, recently appointed city physician of Chattanooga, has selected as his assistant, Dr. John B. Steele.

TEXAS.

Personal.—Dr. Edmund B. Parsons, Palestine, has been made physician for the jail and county camps, and Dr. Henry R. Link for the county farm.

Colored Physicians Meet.—The Lone Star Medical Association convened November 15 in Houston and remained in session two days. The following officers were elected: President, Dr. Benjamin R. Bluitt, Dallas; vice-president, Dr. Gordon Phipps, Corsicana; secretary, Dr. Benjamin J. Covington, Houston, and treasurer, Dr. J. H. Wilkins, Victoria. The association will meet in Dallas next year.

Hospital News.—The All Saints' Hospital Association, Fort Worth, has opened its recently completed hospital building. ——A new hospital and sanatorium is being planned for San Angelo, to be conducted by Sisters of Charity.——The Charity Hospital endowment fund, Houston, has received $30,000 of the $40,000 required for the erection of the building. The site and $20,000 have been given by Mr. George Herman.

VIRGINIA.

Board of Health.—The thirty-third annual report shows that the total number of deaths for 1904 was 1,876; white, 858; colored, 1,018, a decrease over the previous year of 59 from all causes. The annual rate of mortality on the whole population was 18.76 per 1,000. The death rate of the white population was 13.76 per 1,000, and that of the colored 24.49 per 1,000.

Tuberculosis Sanitarium at Ironville.—At a recent meeting held in Richmond of the officers of the Virginia Sanitarium for Consumptives, it was decided if possible to consolidate this society with the organizations of the Associated Charities and of the Medical Society of Virginia. It was contended that there was little use for three societies working for the same ends, but along different lines. It is now the object to bring about co-operative effort and harmony in order that the legislature may be petitioned to take the matter in hand and erect a state sanitarium.

GENERAL.

American Tuberculosis Exhibition.—This exhibition is now being held in New York, as announced in The Journal last week.

Yellow Fever in Cuba.—The health department hopes to stamp out the yellow fever infection and is disinfecting all places where fever cases have occurred. The plague of mosquitoes which was present all summer continues.

N. S. Davis District Medical Association.—The Northeast Missouri Medical Association, which has been reorganized as the N. S. Davis District Medical Association in honor of the late Dr. N. S. Davis, held its second annual meeting in Keokuk, Iowa, November 14. The following officers were elected: President, Dr. Wiliam B. Sisson, Kahoka, Mo.; vice-presidents, Drs. Charles L. Russell, Keosauqua, Iowa, and Robert M. Lapsley, Keokuk, Iowa, and secretary and treasurer, Dr. John E. Parrish, Memphis, Mo.

Railway Surgeons Meet.—The Cincinnati, Hamilton & Dayton Railway Surgeons' Association held its annual meeting in Dayton, November 14. The question of merging the association with the Association of Surgeons of the Erie Railway was discussed, but no definite action was taken. The election of officers resulted as follows: President, Dr. Frederick D. Barker, Dayton, Ohio; vice-presidents, Drs. Frederick W. Robbins, Detroit, Mich.; Samuel E. Munson, Springfield, Ill., and William S. Hoy, Wellston, Ohio; secretary, Dr. Mark Millikin, Hamilton, Ohio; and treasurer, Dr. William A. Galloway, Xenia, Ohio.

The Edward N. Gibbs Memorial Prize.—The New York Academy of Medicine announces that the sum of $1,000 will be awarded to the author of the best essay on "The Etiology, Pathology, and Treatment of the Diseases of the Kidney." An essay must show originality in order to obtain the prize. The competition is open to the members of the regular medical profession of the United States. Essays must be received on or before January 1, 1907, by the recording secretary of the New York Academy of Medicine, at 17 West Forty-third street. The prize is awarded triennially. In 1902, two essays were received, but no prize was awarded, as, in the opinion of the trustees, neither of the essays was worthy of it.

Plague in Hawaii.—Passed Assistant Surgeon Hobdy, of the Public Health and Marine Hospital Service, reports two fatal cases of plague in Honolulu during the latter part of October. A Chinaman, admitted to the hospital with symptoms of plague, died, and the autopsy confirmed the diagnosis. The second patient was a woman who died after an illness of four days. The case was reported as suspicious by the attending physician, a Japanese, but unfortunately his suspicions did not develop till after the patient's death. Autopsy showed conclusively that the death was due to plague. In this case, Dr. Hobdy states that there were many contacts and he instituted outgoing quarantine. This action, he says, was necessary because of the large number of Japanese who were to leave for the coast two days later. Dr. Hobdy also reports other deaths which seemed suspicious, and some of which were proved by autopsy to have been due to plague.

Report of the Surgeon General of the Navy.—In his annual report for the year ending June 30, 1905, Surgeon-General Rixey states that the medical corps of the Navy is at a disadvantage in the mind of a prospective candidate because of the fact that the assistant surgeon of the Navy while on shore duty receives 15 per cent. less than his army colleague. Dr. Rixey believes that the removal of this apparent discrimination will be of service in successfully recruiting the corps. In reviewing the work of the service he mentions the development of the naval stations at Charleston, S. C., and at Guantanamo, Cuba, and invites attention to the fact that no provision has been made for a naval hospital at either place. The need for a hospital at Guantanamo, he states, is immediate and urgent from the fact that naval vessels are frequently at that place and there are no hospital facilities available. The report includes detailed statistics of the health of the navy and of the marine corps during 1904.

FOREIGN.

Prussian Convalescent Home for Army Officers' Wives and Daughters.—A convalescent home for the members of the family of underofficers in the Prussian army has just been inaugurated at Idstein in Taunus.

Correspondence of Frederick the Great With Physicians.—The Prussian Academy of Sciences has granted $200 to Dr. G. L. Mamlock to aid in the publication of the correspondence between Frederick the Great and various physicians.

Smallpox and Yellow Fever in Brazil.—Consul Ayme, at Para, reports that the epidemic of smallpox is assuming serious proportions and that there are about 20 new cases daily. He also states that there has been a great deal of yellow fever lately.

General Inspector of the Insane at Berlin.—Besides the three asylums for the insane or feeble-minded at Berlin, a large number of idiots and epileptics are boarded out in private establishments. A central office for the entire system has just been organized and given in charge to the director of the asylum at Lichtenberg, Dr. Moeli, who has been appointed general superintendent of the insane in the Berlin district.

Witchcraft Approved in the German Courts.—A woman was sentenced at Coburg to three months' imprisonment for obtaining money under false pretenses by alleged medical practices. During the appeal proceedings a large number of witnesses testified that there had been no deception, that the woman had unmistakably fulfilled her promises to conjure witches and cure sick cows by her words, and that the witnesses had not been defrauded in any way. The suit against the woman was therefore dismissed.

Three Years' Confinement for Drunkards in Great Britain.—It has been announced that greater stringency is to be observed in the working of the English inebriates act. It has been found that permanent good can not be effected by confining persons in an inebriates' home for one or two years, and the judges have been requested to suggest to the justices that all these individuals should be sent to homes for three years, because in almost every case in which the individual was confined in a home for three years success had been attained.

Physicians Protest Against High Price of Meat in Germany.—One of the official medical organizations of Munich has published a public protest against the present high price of meat. It calls the attention of the authorities to the inevitable injury to health, both for the present and the rising generation, from the prevailing high prices of the most important articles of food, especially meat. The protest asks for reduction in customs duties and abolition of measures restricting importation of canned and dried meats. As physicians and hygienists the subscribers urge that steps should be taken at once to prevent further deterioration of the health of the people of Bavaria.

The Royal Society Medals.—The Royal Society (Great Britain) has awarded medals to Prof. Charles Scott Sherrington, F.R.S., for his researches on the central nervous system in relation to reflex action; to Prof. John Henry Poynting, F.R.S., for his researches in physical science, especially in connection with the constant of gravitation and the theories of electrodynamics and radiation; the Copley medal to Prof. Mendeléef, of St. Petersburg, for his contributions to chemical and physical science; the Davy medal to Prof. Albert Ladenburg, of Breslau, for his researches in organic chemistry, especially in connection with the synthesis of natural alkaloids, and the Hughes medal to Prof. Augusto Righi, of Bologna, in recognition of his experimental researches in electric science.

Postgraduate Course in Professional Organization Matters and Contract Practice.—The *Leipziger Verband* has arranged for a series of lectures on these subjects to be delivered at Berlin to medical students and recent graduates under university auspices. The lectures are to be delivered Friday evenings, commencing in November. The first is to be by Kühler, on "The Physician and the Public"; the second, by A. Peyser, on "Organization of the Medical Profession"; the third by R. Lennhoff, on "The Physician and Sickness Insurance Societies"; the fourth, by H. Joachim, on "Demand and Supply of Medical Positions"; the fifth, by Davidsohn, on "Medical Benevolent Institutions"; the sixth, by Bensch, on "Medical Insurance," and the seventh by Hesselbarth on "Legal Protection of the Physician." It is proposed to follow this series with another on allied themes in the next semester, and to publish the addresses in pamphlet form to reach a wider audience.

Surgeon's Responsibility in Case of "Chloroform Death."—A French surgeon was sued for $10,000 on account of the death of a patient from syncope during the commencement of anesthesia. The court decided that the surgeon's technic was flawless, but that he had omitted to warn the patient and his family of the dangers of chloroform anesthesia in general, especially for persons more or less addicted to alcohol, as was the patient in the case. The judge stated: "As the operation was not undertaken for vital reasons, but merely for the reduction of a dislocated shoulder, the surgeon should have explicitly informed the patient and his family, and have obtained their consent before undertaking the administration of chloroform for an operation that was not strictly necessary. In case of vital necessity, the surgeon has only his science and his conscience to consult, but in the case in question this does not apply." The surgeon was sentenced to pay $1,600 and costs. The full text of the decision is given in the *Gaz. Med. Belge* for November 9.

British Physicians Honored.—King Edward, on the occasion of his birthday, knighted Dr. James Barr, physician to the Royal Infirmary, Liverpool, and lecturer on clinical medicine in University College, Liverpool; Mr. Arthur Chance, president of the Royal College of Surgeons in Ireland, surgeon to the Mater Misericordiæ Hospital, Dublin, formerly; Dr. Theodore Thomson, one of the medical inspectors of the local government board, has been made a companion of the Order of St. Michael and St. George, in recognition of services rendered in connection with sanitary matters to the foreign office and colonial office; he has represented Great Britain at international sanitary conferences. The same honor was conferred on Dr. Marc. Armand Ruffer, president of the Egyptian Sanitary Board, distinguished for his researches in bacteriology and pathology; and on Dr. Featherstone Cargill, first class resident in the Protectorate of Northern Nigeria. Sir Felix Semon, C.V.O., physician extraordinary to his majesty, has been advanced to be a Knight of the Royal Victorian Order.

Enteric Fever in the British Army.—Dr. H. E. Leigh Canney, an acknowledged authority on the subject, recently delivered an address on "The Toleration of Enteric Fever by the British Army." His address was a strong indictment of the lack of medical organization that prevailed in the army. He declared that the condition of the British army at Bloemfontein was precisely similar from the point of view of sanitary organization to that of the royalist and parliamentarian armies in 1642, when both sides being close together could not fight on account of disease. Figures were given showing that the incidence of typhoid fever in the British army represented in India and South Africa was extremely large when it was realized that the incidence of this disease in the army in Great Britain had been reduced to one-seventeenth of what it was between 1837 and 1846; at Gibraltar, to one-eighteenth, and at Malta to one-fortieth. The condition in India, he said, was comparable only, though considerably worse, with that of the army of England, long before sanitation was known, and the condition in South Africa was more serious still. Dr. Canney said that he is in favor of a "school of sanitation for officers" being established forthwith as well as a handbook of sanitation for the field and barrack being provided for officers.

To Prohibit Use of White Lead.—One of the Paris daily papers recently organized a public scientific meeting to agitate the question of the suppression of white lead. It was held Saturday evening in the Trocadero hall, and Dieulafoy presided, with Brouardel and other prominent physicians and hygienists on the platform. The principal address was made by Mosny, who stated that in his small service at the Saint Antoine hospital, with only 60 beds, he averages 23 cases of lead poisoning every year. He drew the picture of the slow poisoning from the use of white lead in paints, etc., and discussed the measures necessary to prevent it, and save a large class of citizens and their descendants from insidious physical injury. Whether official regulation, substitution of zinc for lead, or prohibition of the use of white lead would prove most effectual he did not venture to decide. Regulation has been tried, but met with such opposition on the part of the proprietors that the regulations were never successfully enforced. The substitution of zinc white for white lead was also officially decreed in France at one time, but the higher price of the zinc caused the surreptitious use of the lead to such an extent that the regulation became practically a dead letter. The complete prohibition of the use of white lead is opposed only by the manufacturers of the latter. A bill has been passed by the chamber of deputies and is now before the senate, forbidding the use of white lead completely, but giving the manufacturers four years in which to close up their establishments. Several of the speakers emphasized the importance of training the young in hygiene in regard to prevention of lead poisoning. Adults seldom realize its importance until too late.

Organization of the Profession in Bohemia.—The last *Prager med. Wochft.* devotes several pages to an urgent appeal for the formation in Bohemia of a society for mutual aid in resisting unjust exactions by the sickness insurance companies (Krankenkassen). It is to be modeled on the *Leipziger Verband* for promoting the economic interests of the physicians of Germany, the success of which has surpassed all expectations. It now numbers 17,000 members, who pay annual dues of about $5. It has, to date, aided in 318 affairs in which there was conflict between the Krankenkassen and their medical officers, and all but eight have terminated in favor of the physicians. The pecuniary results for the medical officers of the sickness insurance societies amount to a total of $500,000 a year, gained for the profession by the efforts of the *Leipziger Verband*. Besides this, fully three times as many affairs were settled in favor of the medical officers without the necessity of a conflict, the total pecuniary results amounting thus to fully $1,600,000 a year gained for the medical officers of the sickness insurance societies by the direct or indirect backing of the organized profession in the *Leipziger Verband*. In Bohemia it is proposed to organize a similar society in each district, and in time to combine them into a national organization. The district society must have the backing of at least half of the physicians, and stirring appeals call on them to organize and reap the benefit of such [illegible] The prestige of the whole profession is raised [illegible] tion now accorded the sickness insurance [illegible] as the results of organization, and the same is hoped for Bohemia. The application for membership contains a clause imposing a penalty of about $400 for action contrary to the aims of the society.

Epidemic Psychoses.—The *Russische Med. Rundschau* discusses the mutiny on the *Potemkin* of the Black Sea fleet, quoting an article by Jacoby, who takes the view that the mutiny was the result of an epidemic psychosis among the men. He regards the Paris commune of 1870 as an instance of the same kind of psychic commotion. The revolutionary movement at that time spread to other cities in France and into Italy and Spain. At Carthagena the crew of one of the naval vessels mutinied and bombarded the town. Jacoby met several of the members of the crew two years later and noticed that a number among them showed evidences of morbid minds, although their reasoning faculties were intact. In the present conditions in Russia, the editorial continues, instances of collective, induced psychoses are easily possible. One needs only to know the psychic condition of the Russian populace at the present time readily to understand it.

International Congress of Drops of Milk.—This fanciful name is given in Europe to the charity infant milk supply stations, combined with medical inspection of the infants and advice to mothers. An international conference of persons interested in the subject has just been held at Paris. The members of the congress visited the successful infant consultations in Paris and at Rouen and Fécamp, and decided to form an international union with headquarters at Brussels, where the next congress will be held in September, 1907. The official definition of the term *gouttes de lait* (drops of milk) was announced as "A work which fights against infantile mortality by every possible means; it gives advice to the mothers; encourages breast feeding, and supplies proper milk when the breast milk is insufficient or defective." The congress voted in favor of legislation for control of milk for the use of infants separate from the general milk supply. Ulecia, of Madrid, has founded a very successful infant consultation in his city and he remarked that to give milk to the mothers without medical advice at the same time, was high treason against motherhood (*lèse-maternité*). The charity milk supply stations in Great Britain are not under medical control, and there is no attempt at the "infant consultations" which have been developed to such perfection in France, as mentioned recently in these columns on page 1366. They have recently been introduced into Berlin, Vienna, Buda-Pesth and Buenos Ayres on the French models, and the Congress passed resolutions urging their still more general adoption. Four have been founded in St. Petersburg, but only one has survived to date. J. Bertillon proposed that infantile mortality should be classified by age, the first group including infants one to four days old; the second, five to nine; then ten to fourteen, fifteen to twenty-nine, one to three months, three to six months, and six to twelve months.

LONDON LETTER.

Increase of Inmates in the Asylums of Scotland.

The government report on lunacy in Scotland shows that the proportion of pauper insane resident in asylums per 100,000 of the population has steadily increased during the last twenty-five years. This does not appear to depend on increase of admissions, but on a diminution of the discharge rate. The reasons given for this are as follows: An increased unwillingness to retain insane persons in private life or to receive them back from asylums; the admission in large numbers of old and physically disabled persons who are unfit to be discharged; lessened activity on the part of parochial authorities in removal from the asylum of patients who could be cared for outside.

Death from a Wasp Sting.—The following remarkable case was investigated by the Sussex coroner. The wife of a workingman was drinking a glass of stout when she suddenly felt a pain in the throat as a result of some body which she had imbibed with the liquid. She coughed it out and found that it was a wasp. Beyond the natural fright and some discomfort in the throat, she seemed but little the worse for her experience, and for the next few days was comparatively well, so that medical advice was not sought. Then she felt faint and ill, but continued to pursue her ordinary vocation until the sixth day after the sting, when she called in a physician. He found little evidence of serious illness, but her symptoms rapidly increased and assumed a grave character. Cellulitis of the throat and nasal passages developed and death from septicemia followed in two days. This case differs from the ordinary cases in which dangerous symptoms follow wasp stings in that an interval elapsed between the sting and the onset of symptoms, and that these were due to cellulitis, and not to toxemia.

Pharmacology

The Square Deal in Pharmacy.

There are persons who are living more or less voluntarily in a fog, so far as concerns a real comprehension of the purpose of establishing the Council on Pharmacy and Chemistry. The issue is so plain that it should hardly need restating, but that further explanation is necessary is evident when we find the official journal of one state association joining hands with those who naturally are in opposition to the work of the reform.

Tersely stated, the object is to secure honesty in pharmacy. Apart from the creation of the false issues, the setting up of straw men, there are no two sides to the question. The profession is demanding nothing chimerical or difficult, but it should and must be recognized at once that the dishonest and fraudulent methods of those who are supplying physicians with medicinal articles must be stopped. The profession, the Association and the Council are desirous of bringing about this absolutely essential reform with as little friction and injury as possible. But in the past mild protests of a general character have failed to check the evil, so that the adoption of the present effective method became inevitable.

Nothing short of exposing fraud by giving specific examples will compel reform.

The profession needs attractive and reliable pharmaceuticals and welcomes the legitimate efforts of honest manufacturers. Those manufacturers who adopt the platform of the Council on Pharmacy and Chemistry—which is conservative and requires only honesty—are sure of the support of the profession. Common every-day honesty is all that is required, and those who are thereby now squealing so loudly are arousing questions as to their motives and methods.

There being not the least desire or need of punishing anyone for past offenses, it would seem to be an easy matter for the medical profession and the manufacturers to meet on the one common ground of square dealing and to arrange matters for the future so that harmony and honest methods may prevail. So long as there are fake preparations and misleading "literature" THE JOURNAL will continue to expose them, as a matter of duty to the medical profession and to the public. In the meantime, all who are ready to stand with us on the "square deal" platform will be welcomed.

Birds of a Feather. A Menace to the Public Health.

The list of the members of the Proprietary Association of America, which we published two weeks ago, is but another illustration of the general truth of the old adage that "Birds of a feather flock together." With the exception of a comparatively few firms, the concerns enumerated are engaged in a business that is neither honorable nor commendable. For the physician who is at all interested in the progress of his profession, or in the maintenance of the public welfare, this list should prove highly instructive, especially since the proprietary association is practically forcing the newspapers of the country to publish matter they supply to counteract the movement against the patent medicine fraud.

The preparations that are enumerated under the several firm names are important, as they constitute a goodly portion of the articles that are sold directly to the public. But it will be noticed that many of them were at one time considered "ethical," because they were advertised directly to, and were prescribed by, physicians. Many of them are composed of more or less active medicinal substances and thus are a direct menace to public health, when, as is now the case, they are used indiscriminately and without regard to their danger certain conditions. To-day their common use by the public is an indictment of the credulity or foolishness, or both, of a large number of medical practitioners. While even the most reckless users of nostrums would scorn to prescribe "Bradfield's Female Regulator," "Liquozone," "Peruna," or "Wine of Cardui," thousands of otherwise intelligent physicians are daily prescribing "ethical proprietaries" that are not one whit better. Many other "ethical proprietary" preparations are gradually, but surely, going, or have gone, to the patent medicine class by the aid of physicians. Such, for instance, as "Vin Mariani," "Tongaline," "Antikamnia," "Kutnow's Powder," "Gray's Glycerin Tonic Comp.," "Peacock's Bromides," "Chionia," "Cactina Pilletts," etc.

All of these and many more of the present-day "ethical" preparations that are "advertised only to the medical profession" may be found enumerated in the price lists of the larger cut-rate drug stores, and are daily sold to men, women and children, over the counter, at from 20 to 50 per cent. less than they are furnished on physicians' prescriptions.

The question naturally arises, Who is to take the blame for the ultimate consequences of the resulting haphazard self-medication? Who is to be held responsible for the overstimulation and subsequent collapse, the deranged metabolism and the frequently acquired dangerous, if not fatal, drug habits? Before we blame the public for the indiscriminate use of "patent medicines" it will be well for many of us to ask ourselves how far we are responsible for some of the "patent medicine" taking.

Medical Papers and Proprietary Medicines.

Our contemporary, THE JOURNAL of the American Medical Association, is not having by any means an easy task in its attempt to enlighten the physicians of the states on various points regarding the trade in proprietary articles. Many of the proprietors of much-advertised preparations regard the undertaking as a direct attack on their trade, and they are ready to use any weapon in self-defense. In particular, many of the less important medical papers, whose existence depends in great part on the returns from their advertisement columns, have published violent attacks on THE JOURNAL and on the personality of its editor. In some cases these attacks are little else than paraphrases of the matter to be found in the advertising columns of the same papers. How strong a hold some of these manufacturing druggists have over the medical press in America is shown in an amusing way by a letter to THE JOURNAL itself from the proprietors of a much-vaunted hematinic, many of whose advertisements are doubtless at present in our readers' waste-paper baskets. In an editorial article in our contemporary some months ago, the statement occurred that "the day of blind reliance on iron, quinin, and tonics in general in the treatment of anemic conditions in tropical countries is past, never to return." This seemingly innocent remark drew forth an indignant letter of remonstrance from the proprietors of the hematinic, who regard it as a direct "slap in the face," since it is alleged to cast a slight on their preparation, and they threaten in consequence to withdraw their advertisement. When an attempt is made to restrain such a paper as THE JOURNAL of the American Medical Association from free comment, one may judge the freedom permitted to less independent and less scrupulous journals.—*Medical Press and Circular*, London.

Multiple Neuritis Following the Use of Peruna.

In the report of a recent meeting of the Academy of Medicine of Cincinnati, as published in the *Lancet-Clinic*, Nov. 4, 1905, the following interesting case is reported by Dr. George E. Malsbray:

"In September, 1904, I was called to see a woman just past the meridian of life, whom I found suffering from multiple neuritis. The nerves of the lower extremities, and some of the nerves of the head were successively involved. There was no history nor evidence of exposure to cold, rheumatism, nor exhaustion to act as etiologic factors. Finally, after ruling out other causes of the disease, it became evident that the patient must have been taking alcohol in some form, notwithstanding the fact that she was a refined lady and an earnest advocate of temperance, who would not knowingly indulge in any form of alcoholic beverage. I asked her what she had been drinking. She was shocked; she disclaimed being a tippler either in public or private. I asked her what medicine she had been taking. She stated that she had not been under the care of a physician. Further examination into the history of the case revealed the fact that the patient had been using 'peruna' for a long time, taking the nostrum under all sorts of pretexts. After explaining the case to the patient, she readily consented to stop the 'peruna' cocktails. As stated, first one nerve, then another, was attacked. Finally, after about three months' treatment with the usual remedies for multiple neuritis, the patient apparently recovered. . . . The patient has since relapsed, as is common in this disease, showing that the recovery was not complete."

Apothecaries and Patent Medicines.

To show what may be done by an apothecary who sees in the patent medicine he sells something beside the profit he reaps therefrom, we quote from a letter recently received from a Canadian druggist. He refers to a move of the patent medicine manufacturers to prevent price cutting, and incidentally to suppress what they denominate substitution:

> At first sight the proposition was a perfectly equitable one, but on close examination I found that anyone who signed it would be under the necessity of passing out any nostrum asked for without comment. Now, when anyone comes in and asks me for a bottle of these swindles, I always give them what they ask for, but usually with my opinion of the fraud thrown in. In certain cases it is useless to do this, as it has no effect. I am thankful to say, however, that I have been instrumental in killing the sale of some hundreds of bottle of these frauds. Another vile swindle I am "down on" is the advertised tuberculosis cure. I believe that this one county contributes $10,000 a year to the maintenance of those two harpies, —— and ——. I keep a small stock of the —— "remedies," and dispense them under protest. ——'s literature is so infernally offensive to the medical profession, that both my competitor and I have blacklisted the goods, and will have none of them.

This sentiment from a druggist is unusual, and hence the more commendable. That the apothecary has the legal right ta sell his customers that for which they ask can not be denied; his opportunity for enlightening the public in regard to nostrums is not so thoroughly appreciated.—*American Medicine.*

Chicago Medical Society Indorses the Movement.

The Council of the Chicago Medical Society, at its last meeting, adopted the following resolutions:

> *Resolved,* That the Chicago Medical Society expresses its hearty approval of the action of the American Medical Association i[illegible]l on Pharmacy and Chemistry to [illegible] drugs and medicinal preparations. [illegible] an investigation is necessary to sift out the numerous and rapidly increasing number of worthless and harmful preparations that are being exploited among the physicians of this country. It has confidence in this Council and wishes to support the Trustees of the American Medical Association in carrying on the work already instituted by this body.
>
> The Chicago Medical Society also approves the action of THE JOURNAL of the American Medical Association in its campaign of educating the medical profession concerning the evils of secret nostrums and urges it to continue in the good work. FRANK X. WALLS, Secretary.

Work of the Council Indorsed.

We are officially informed that at a meeting of the Aux Plaines Branch of the Chicago Medical Society, held in the Phoenix Hospital, Maywood, November 24, a vote of thanks was unanimously tendered THE JOURNAL of the American Medical Association for the excellent work of its Council on Pharmacy and Chemistry with reference to the proprietary remedy evil.

Miscellany

Obstetrical Binders.—Povey, in the *Dominion Medical Monthly,* gives the following uses of the obstetrical binders as determined by his own personal experience. He advocates its use in practically all cases. The binder itself consists merely of a piece of unbleached muslin long enough to surround the abdomen and broad enough to extend from the pubes to the sternum; two pieces of the same material, three inches wide and eighteen inches long, are securely sewed to the posterior border (to avoid the use of safety pins, on which the patient would have to lie), so that when the binder is applied they hold it down in position, and, being pinned anteriorly above the pubes, hold the vulvar pads in position. Several of these simple binders should be on hand, so that as one becomes soiled another may be applied. A good sized pad of absorbent cotton or other suitable material should be placed on the abdomen just back of the uterus after that organ has been lifted forward. This pad is held firmly in this position while the previously arranged binder is pinned snugly by the nurse, beginning at the sternal end and pinning downward. The hand is gradually removed as the binder is pinned, so that the pad is held in place. The binder is pinned tighter above than below. The vulvar pad is placed in position and the two posterior straps are drawn up and pinned anteriorly, thus holding the binder down and the vulvar pad in position. Sometimes two additional straps can easily be adjusted. The binder may be tightened as the uterus contracts, and by the tenth day, when the uterus is within the pelvis, the pad may be entirely removed and the binder applied firmly throughout its entire length. The advantages of the binder thus applied are: 1. The patient is thus made comfortable. After the uterus has been delivered of its burden the patient necessarily feels a tremendous relief from weight, pressure and distension. 2. It permits the patient to be moved and turned in bed without the fear that something terrible is going to happen. For a patient to be turned from one side to the other, her position being changed when she becomes wearied, is of very great advantage in guarding against retroversion, descent and prolapse of the uterus. 4. It has a decidedly beneficial effect on the mental state, for the patient believes that her maidenly contour will be restored. Thus her mind is placed at ease, and this is no small factor in the establishment of an uneventful convalescence. He states that he has seen just as many cases of "after pains" when the binder was not applied as when it was, and in some cases in which he has removed the binder the pains continued. He is of the opinion that when not properly applied it causes retroversion, descent or prolapsus of the uterus, but when applied as he directs, thus allowing the patient to be turned and not requiring her to remain on her back, it possesses advantages far above the objection raised, and even is a great factor in preventing the mentioned sequela. The patient is of the opinion that it actually helps to restore the maidenly contour. All in all, it seems to Povey that the obstetrical binder is a rational, feasible and simple device, and when in the hands of a judicious obstetrician a decided help, comfort and blessing to womankind.

Preparations for Confinement.—De Forest, in the *Medical News*, gives the following list of articles which should be prepared and that should be within the reach of all save the very poor, and which does not include non-essentials:

For Use of the Mother.—Six towels, freshly laundered; three sheets, freshly laundered; one rubber sheet; one labor pad, made of newspapers and clean muslin, or quilted mattress protector: thirty-six lochial guards, preferably of gauze and paper wool, or of cotton waste, or of cotton and gauze sterilized: three binders, abdominal, 18 inches wide and circumference of hips; two binders, breast, made from pattern; twenty-four safety pins, Clinton, large No. 3; forty-eight medium No. 2; thirty-six small No. 1; two washbowls, earthern or agate; one water pitcher, earthen or agate; one slop jar; ten yards absorbent gauze for wash cloths, etc.; one fountain syringe (one gallon); one glass douche tip, for syringe; one glass drinking tube; one douche pan, white enamel or agate ware; two hand brushes; one hundred antiseptic tablets, 7½ grains, bichlorid, blue; eight fluid ounces of lysol; one tube of vaselin; four fluid ounces Squibbs chloroform.

This list is printed on a card six inches square. On the front of the card a space is left for the name, address and telephone number of physician, patient and nurse. On the back page, after it has been folded vertically, is the special direction:

"Urine: Send half a pint of morning urine to doctor's office every two weeks after the sixth month."

At the time of labor the room should be cleared of all needless articles and ornaments. The carpet should be protected with a layer of newspapers, with a sheet tacked over them. The bureau mantel and table tops should be cleared and protected with paper and covered with clean towels for the instruments, etc. There should be plenty of hot and cold water and ice in readiness. These supplies should be at hand, in good order and easily accessible.

Means to Correct the Dispensary Abuse.—Imhofer of Prague discusses, in the *Prag. med. Wochft.* for October 5, the best means to combat the dispensary abuse, which has assumed large proportions there. He suggests as the measures best adapted for local conditions that all applicants to the dispensary should have to pass first through a room where an inspector demands a certificate testifying to the bearer's lack of means or a line from a physician indorsing his application. A card is then given the applicant and he can then proceed to the dispensary proper, or to the clinic or ward. No one is admitted to the dispensary or clinic without presentation of a numbered card of this kind. The inspector is always at liberty to pass an applicant directly into the dispensary or clinic when circumstances demand the avoidance of red tape delay, and an applicant accompanied by his physician should also have free right of way. By some such sifting process the dispensaries and hospitals could be kept free for the poor, while those able to pay for medical attendance would be excluded from them.

Marriages

John L. Sweeney, M.D., to Miss Elsie F. Weeks, both of Chicago, November 15.

Howard E. Wooden, M.D., to Miss Edith Marie Collier, both of Baltimore, November 8.

Wade Hampton Nash, M.D., to Miss Julia A. Pesold, both of St. Louis, November 14.

Roger Griswold Perkins, M.D., to Miss Edna Brush, both of Cleveland, November 14.

Orrin Sage Wightman, M.D., to Miss Purl Parker, both of New York City, November 9.

Joseph N. Roy, M.D., Webster, Mass., to Miss Eva Lambert of Pascoag, R. I., October 31.

Robert W. Williams, M.D., to Miss Emma Kees, both of Cleveland, Ohio, November 14.

George E. Saunders, M.D., to Miss Helen Rogers, both of Des Moines, Iowa, November 15.

J. Samuel Price, M.D., to Miss Maybel Hasbrouck, both of Beaumont, Texas, November 12.

John Wesley Phillips, M.D., to Miss Laura Van Dyne, both of Troy, Pa., November 15.

William S. Jackson, M.D., to Miss Blanche Hambitzer, both of Houghton, Mich., November 15.

William A. Selman, M.D., Atlanta, Ga., to Miss Elizabeth Crouch of Gay, Ga., November 15.

A. F. Johnson, M.D., Petersburg, Neb., to Miss Florence Hall of Exeter, Neb., November 22.

W. Price Zimmerman, M.D., Batesburg, S. C., to Miss Mary Swygert of Peale, S. C., November 9.

Guy Stone, M.D., Keswick, Iowa, to Miss Agnes Kay Chubb of Michigan City, Ind., November 15.

Adelbert D. Head, M.D., to Miss Sarah Elizabeth Roberts, both of Syracuse, N. Y., November 21.

James A. Young, M.D., Pearl, Idaho, to Miss Anne Llewellyn Walter of Boise, Idaho, November 15.

Leander B. Dean, M.D., Blaine, Ky., to Miss Mollie Hutchinson of Fallsburg, Ky., November 16.

Warren J. Karterman, M.D., Hepler, Pa., to Miss Minnie M. Kehler of Kehler, Pa., November 8.

Browning G. Pitts, M.D., Lydia, S. C., to Miss Belle Watson of Ridge Spring, S. C., October 19.

Joseph C. Rauth, M.D., Upper Sandusky, Ohio, to Miss Lillian Ley of Tiffin, Ohio, November 22.

Charles H. North, M.D., Dannemora, N. Y., to Miss Luella B. Robinson of Clyde, N. Y., November 15.

Wilbert E. Fordyce, M.D., to Miss Nellie Elizabeth Humphrey, both of Oelwein, Iowa, November 16.

Edward Marshall Sandidge, M.D., Clifford, Va., to Miss Lottie Walker of Salem, Va., November 15.

John Walker, M.D., Lynchburg, Va., to Miss Laura May Stebbins of South Boston, Va., November 29.

Samuel Warren Hobbs, M.D., Aurelia, Iowa, to Miss Harriet D. Peters of Clinton, Iowa, November 11.

Elwin W. Capen, M.D., Monson, Mass., to Miss Fannie Louise Barnes of Westfield, Mass., November 8.

Hugh O. Morgan, M.D., to Miss Olga U. Von Hagen, both of Elkton, S. D., at Brookyngs, S. D., November 3.

Lewis N. Foote, M.D., Brooklyn, N. Y., to Miss Mabel Shull Ackler of Ilion, N. Y., at Utica, N. Y., November 15.

Robert Lawrence Corbell, M.D., Norfolk, Va., to Miss Nancy Alberta Webb, at Vienna, Md., November 21.

Clarence Fontaine Maury Leidy, M.D., Philadelphia, to Miss Margaret Howard Ridgely, at Baltimore, November 25.

Harry E. Sutton, M.D., Cold Springs, Minn., to Miss Rosemund M. Garner of Spokane, Wash., in Watertown, S. D., November 16.

Robert E. Noble, M.D., first lieutenant and assistant surgeon, United States Army, to Miss Ella Lupton of Auburn, Ala., November 23.

Walter C. Chidester, M.D., lieutenant and assistant surgeon, United States Army, to Miss Marie Bull of San Francisco, November 22.

Levy M. Hathaway, M.D., lieutenant and assistant surgeon, United States Army, to Miss Mary Frances Weir of Owensboro, Ky., November 27.

Deaths

De Villo White Harrington, M.D. University of Buffalo (N. Y.) Medical Department, 1871; a member of the American Medical Association, New York State Medical Association, Erie County Medical Society, Buffalo Academy of Medicine, and Cavalry Society of the United States Army; a veteran of the Civil War; professor of genitourinary and venereal diseases in the University of Buffalo Medical Department; consulting physician to the Buffalo General Hospital and Buffalo City Hospital; from 1876 to 1885 attending surgeon at the Sisters' Hospital; one of the best-known physicians of western New York, died at his home in Buffalo, November 20, from heart disease, after a long illness, aged 61.

Andrew Martin Pierce, M.D. College of Physicians and Surgeons in the City of New York, 1873; a member of the American Medical Association; member and once vice-president of the Massachusetts Medical Society; member and many times an officer of the South Bristol Medical Society; once president of the New Bedford Medical Society; for years physician to the poor department of New Bedford, and for twenty years a member of the staff of St. Luke's Hospital, died at his home in New Bedford, November 6, after an illness of about one year, aged 53.

Augustus Choate Hamlin, M.D. Harvard University Medical School, Boston, 1855; assistant surgeon of the Second Maine Volunteer Infantry; brigade surgeon and finally lieutenant-colonel in the Army during the Civil War; made chevalier of St. Ann by the Czar of Russia in 1878; commissioner from Maine at the Yorktown centennial in 1881; surgeon-general of Maine from 1882 to 1886; twice mayor of Bangor; widely known as an author, artist and as an authority on tourmalines, died at his home in Bangor, November 20, aged 76.

Benjamin Myers, M.D. Jefferson Medical College, Philadelphia, 1869; formerly state representative and probate judge of Ashland County, Ohio; a veteran of the Civil War; for three years a member of the board of trustees of the Ohio Central Insane Asylum, Celina; in 1884 mayor of Ashland, died at his home in Ashland, November 21, from pneumonia, after an illness of four days, aged 63.

William A. Burns, M.D. Medical Department of Western Reserve University, Cleveland, Ohio, 1898; a prominent colored physician of Dayton, Ohio; a member of the Dayton Academy of Medicine, died at his home in Dayton, November 19, from typhoid fever, after an illness of three weeks. At a special meeting of the Academy of Medicine, it was voted to attend the funeral in a body, and resolutions of sorrow and respect were adopted.

Charles M. Zeh, M.D. Castleton (Vt.) Medical College, 1848, one of the oldest physicians of Newark, N. J.; a member of the board of health and health officer for many years; a member of the Medical Society of the State of New Jersey and the Essex County Medical Society; consulting physician to St. Michael's Hospital, died suddenly at his home, November 13, from cerebral hemorrhage, aged 78.

Robert Edwin Coy, M.D. Chicago Medical College, 1891; a member of the American Medical Association, Illinois State Medical Society, and Winnebago County Medical Society; a member of the attending staff of the Rockford City Hospital, died at his home in Rockford, Ill., November 21, from pneumonia, after an illness of about one week, aged 57.

Henry A. Tingley, M.D. University of Buffalo (N. Y.) Medical Department, 1848; one of the oldest practitioners of Susquehanna County, Pa.; president of the school-board of Susquehanna; a surgeon in the Army during the Civil War, and president of the first soldiers' election board, died at his home in Susquehana, October 28, aged 85.

Andrew Thustin Pearsall, M.D. College of Physicians and Surgeons in the City of New York, 1861; assistant surgeon and late brigade surgeon in the Confederate service during the Civil War; local surgeon for the D., L. & W. Railway, died at his home in Owego, N. Y., from diabetes, after a long illness, November 17, aged 66.

Daniel H. Tarbell, M.D. (Philadelphia Med. and Surg. Reg.), 1880; a veteran of the Civil War; twice coroner of the northern district of Rensselaer County, N. Y.; president of Schagticoke, N. Y., for five terms, and health officer for twenty-eight years, died at his home in that village, November 10, after a long illness, aged 63.

John I. French, M.D. Tufts College Medical School, Boston, Mass., 1896: a member of the American Medical Association and Massachusetts Medical Society; instructor in materia medica and therapeutics in the Tufts College Medical School; police surgeon and member of the Board of Health of Winchester, Mass., died at his home in that city, November 18, from nephritis, aged 44.

William A. McCord, M.D. Vanderbilt University Medical Department, Nashville, Tenn, 1883; a member of the American Medical Association; one of the most prominent practitioners of Marshall County, Tenn., died at his home in Lewisburg, November 15, after a prolonged illness from disease of the stomach, aged 47.

Zaccheus Test, M.D. Department of Medicine of the University of Pennsylvania, 1855, but since 1859 not a practitioner owing to ill-health; one of the best-known educators of Indiana, died at his home in Richmond, November 3, from cerebral hemorrhage due to a fall downstairs two days before, aged 77.

William M. Mahoney, M.D. College of Physicians and Surgeons in the City of New York, 1891; an employe of the New York Department of Health; surgeon to the Metropolitan Throat and Nose Hospital, died at his home in New York City, November 16, from pulmonary hemorrhage, aged 47.

Ira Smith, M.D. Kansas City (Mo.) Medical College, 1879; a member of the American Medical Association; widely known in Cass and Bates counties, Missouri, where he had practiced for twenty-six years, was burned to death in a fire which destroyed his drug store at Austin, Mo., November 1.

James Carter, M.D. Chicago Medical College, 1880; a member of the American Medical Association; formerly of Rawlins, Wyo., and president of the Wyoming Medical Association, died at Robertsdale, Ala., where he had gone for his health nine months ago, November 17, aged 54.

James S. Trotter, M.D. University of Buffalo (N. Y.) Medical Department, 1891, of Buffalo; a member of the Erie County Medical Society and of the Buffalo Academy of Medicine, died on his farm at Waterford, Ont., November 11, after an illness of several months.

William F. Tait, M.D. Cincinnati, Ohio, 1866, of Galesburg, Ill.; a veteran of the Civil War; for several years assistant surgeon of the Soldiers' Home, Quincy, died at a hospital in St. Louis, November 8, from malignant disease of the face, aged 69.

Clarence Bartow, M.D. College of Physicians and Surgeons in the City of New York, 1905, ambulance surgeon of Roosevelt Hospital, New York City, was instantly killed by a collision of his ambulance with an automobile truck, November 25, aged 27.

William M. Woodworth, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1853; coroner of Crawford, Mich., and for many years county physician, died suddenly at his home in Grayling, November 1, aged 76.

William A. Bickers, M.D. University of Virginia Medical Department, Charlottesville, 1856, of Crooked Run, Va., died suddenly in his room at the Astor House, New York City, from cerebral hemorrhage, November 20, aged 69.

Julius A. Ruge, M.D. Humboldt Medical College, St. Louis, 1861; assistant surgeon of the Thirty-first Missouri Volunteer Infantry in the Civil War, died at his home in St. Louis, November 14, from heart disease, aged 69.

Whitcomb Phelps, M.D. Medical College of Ohio, Cincinnati, for many years a practitioner of Fort Wayne, Ind., died at the home of his sister in Troy, Pa., from disease of the stomach of long standing, November 12, aged 75.

Michael E. Scannell, M.D. Harvard University Medical School, Boston, 1891, of Worcester, Mass., died in the City Hospital, Worcester, November 16, from heart disease, after an illness of one week, aged 41.

Frank Fennell, M.D. Keokuk Medical College, College of Physicians and Surgeons, Keokuk, 1905, committed suicide by taking morphin at his office in Readlyn, Iowa, while despondent, November 2, aged 25.

Henry Noss, M.D. Long Island College Hospital, Brooklyn, N. Y., 1891, of Brooklyn, died at Verbeck, N. Y., November 18, from cerebral hemorrhage, after an illness of five years with spinal disease, aged 50.

Percy C. Smith, M.D. Medical College of Indiana, Indianapolis, 1898, formerly a practitioner of Swanton, Neb., died at his home in Los Angeles, Cal., November 3, after an illness of four weeks, aged 36.

William Finlaw, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1863, a surgeon in the Army during the Civil War, died at his home in Santa Rosa, Cal., November 17, after a short illness.

George Royal Shafer, M.D. Chicago, 1881, formerly a member of the Illinois State Board of Health, died at his home in Peoria, November 4 ,from rheumatic endocarditis, after a long illness, aged 47.

Norman L. Jones, M.D. Rush Medical College, Chicago, 1882, died at his home in Norton, Kan., November 17, from intestinal obstruction, for which an operation was made a few hours before.

Walter William Robison, M.D. College of Physicians and Surgeons, Chicago, 1897, died at his home in Edelstern, Ill., November 3, from the effects of an overdose of morphin, aged 35.

Willis J. White, M.D. Omaha (Neb.) Medical College, 1891, of Sioux City, Iowa, died at St. Joseph's Hospital in that city, November 13, from pneumonia, after an illness of five days, aged 40.

Thomas L. Painter, M.D. Medical College of Virginia, Richmond, 1868, of Knob, Va., died at the home of his son in Tazewell, Va., November 9, from nephritis, after a long illness, aged 64.

Patrick H. Gallagher, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1864, the oldest physician in the copper country, died at his home in Hancock, Mich., November 21, aged 74.

Mordecai C. Mendenhall, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878, died at his home in Vermilion Grove, Ill., November 15, after an illness of two weeks, aged 70.

Irwin A. Cofer, M.D. Southern Medical College, Atlanta, Ga., 1880, died suddenly from pulmonary hemorrhage, at the home of his nephew in Atlanta, Ga., November 17, aged 43.

Frank H. Russell, M.D. Rush Medical College, Chicago, 1899, died at his home in Kewanee, Ill., November 2, from tuberculosis, after an illness of more than a year, aged 35.

Zachary T. Magill, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876, of Winters, Cal., died suddenly in Berkeley, Cal., November 9, from heart disease.

William B. Dunkle, M.D. Rush Medical College, Chicago, 1863, died at his home in Gelinan, Iowa, November 14, aged 70.

George H. Gilson, M.D. St. Louis Medical College, 1876, died at his home in Raymond, Ill., November 18, aged 56.

Frank M. Harry, M.D. Pennsylvania, 1878; formerly a burgess of Mount Joy, Pa., died at his home in that place, November 20, after a short illness, aged 57.

Arthur O. Bowman, M.D. Bellevue Hospital Medical College, New York City, 1891, died at his home in Roweaville, S. C., November 15, from diphtheria, aged 36.

James Vaughn Tabor, M.D. Harvard University Medical School, 1867, a veteran of the Civil War, died at his home in Hodgdon, Maine, October 24, aged 85.

Thomas Sullivan, M.D. Trinity Medical College, Toronto, Ont., 1881, died suddenly at his office in Springfield, Minn., from heart disease, November 10.

Frank A. Winne, M.D. Pennsylvania, 1878, died suddenly at his home in Brockport, N. Y., November 12, from cerebral hemorrhage, aged 55.

Jason P. Safford, M.D. Detroit (Mich.) Medical College, 1884, of Detroit, Mich., died in Plymouth, Mich., November 12, after a long illness.

Sarah J. Coe, M.D. Michigan, 1878, died at her home in Wilkesbarre, Pa., November 4, from paralysis, after an illness of three years.

John R. Manley, M.D. Cincinnati, 1895, died suddenly at his home in Buckhannon, W. Va., November 16, from heart disease, aged 45.

James F. Meeks, M.D. (Examination, Ohio), a surgeon in the Civil War, died at his home in Hoytville, Ohio, November 11, aged 71.

Joseph Watson, M.D. Ohio, 1853, of Cardington, Ohio, died suddenly in Detroit, Mich., from heart disease, November 2, aged 81.

John E. Gemmel, M.D. Manitoba Medical College, Winnipeg, 1888, died at his home in Rush City, Minn., November 11, aged 45.

Harriet Jackson Ravold, M.D. Illinois, 1894, died at her home in St. Joseph, Mo., November 17, after an illness of three years.

Robert B. Armstrong, M.D. Omaha (Neb.) Medical College, 1893, died recently at his home in Polk City, Iowa.

Francis A. Benham, M.D. Illinois, 1862, died at his home in Elkhart, Ind., November 19, aged 84.

Book Notices

The Physicians' Visiting List for 1906. Fifty-fifth year of its publication. Leather cover, with flap, pencil and pocket. Price, $1.00. Philadelphia: P. Blakiston's Son & Co., 1905.

The fifty-fifth edition of this visiting list is furnished in four different weekly sizes, allowing for 25, 50, 75 and 100 patients respectively per week; in a perpetual edition with spaces for 1,300 and 2,600 names respectively, and in a monthly edition. The system used is different from that of Dr. Taylor's book, which we reviewed last week, in which each patient's account is by itself. This book is more of a day-book; each patient has a line, each day a column, and the entries are made in accordance with a table of signs, which includes all possible contingencies. Following the visiting list proper there are special pages for memoranda, addresses of patients, addresses of nurses, bills presented, vaccination engagements, obstetric engagements, births, deaths, and cash account.

A Text-Book of the Practice of Medicine. By J. M. Anders, M.D., Ph.D., LL.D. Illustrated. Seventh Edition. Cloth. Pp. 1297. Price, $5.50 net. Philadelphia: W. B. Saunders & Co., 1905.

In this seventh edition of Anders' text-book the original plan has been retained and the details of treatment of diseases have been given their proper prominence. Among the new subjects now treated more fully are: the Rocky Mountain spotted fever, splanchnoptosis, myasthenia gravis, pseudotuberculosis, benign cirrhosis of the stomach, intestinal lithiasis and calculi, emulsion-albuminuria, the sequelæ of valvular lesions, the Adams-Stokes syndrome, examination of patients for diagnosis of diseases of the stomach, and Cammidge's tests for glycerose in the urine. The sections on paratyphoid fever, beriberi and trypanosomiasis have been rewritten and the entire volume has been brought up to date. Important additions have been made to the sections dealing with those tropical and subtropical diseases which are being observed with increasing frequency in the temperate zone.

Queries and Minor Notes

TUBERCULOSIS ORGANIZATIONS.

Stanford University, Cal., Nov. 8, 1905.

To the Editor:—Can you furnish a list of tuberculosis leagues and societies in the U. S., also any suggestion concerning a way of getting at the progress of these leagues. I am anxious to secure a bibliography on the subject. James Rosenfeld.

Answer.—The following are the principal organizations working against tuberculosis in the United States:

1. The National Association for the Study and Prevention of Tuberculosis (organized June 6, 1904). President, Dr. Herman M. Biggs, New York; secretary, Dr. Henry Barton Jacobs, Baltimore; executive secretary, Professor Livingston Farrand. Office, 105 East 22d Street, New York City. The objects of the association are, the study of all forms of tuberculosis; the dissemination of knowledge concerning the disease; and the encouragement of its prevention and scientific treatment. The association aims to bring into co-operation all the various agencies working against the disease in America. It has aided in the organization of state and local work in many parts of the country, and by various means is spreading a knowledge of the subject and of its importance, among the people at large. One of the most important of these efforts is the Tuberculosis Exposition, which is to be held in New York, beginning November 28. (See The Journal, Nov. 25, p. 1664..)

2. The Tuberculosis Committee of the Charity Organization Society of New York (organized in June, 1902). Secretary, Mr. Paul Kennaday, 105 East 22d Street, New York City. In addition to much educational, scientific and legislative work, the committee has published a very complete and valuable "Handbook on the Prevention of Tuberculosis," in which every branch of the subject is fully and authoritatively treated.

3. The Committee on the Prevention of Tuberculosis of the Visiting Nurse Association of Chicago (established in June, 1903). Medical Director, Dr. Arnold C. Klebs. Central office, 1414 Unity Building, Chicago. This committee has provided medical and nursing care and instruction for over 1,000 poor consumptives. It has a staff of district physicians and nurses, with offices in the different quarters of the city, by whom patients are attended to, as well as instructed about their disease, its prevention and cure. Special attention is given to the compilation of statistics and to educational work, especially by means of lectures. It also maintains a library and bibliography on tuberculosis. The central office of the committee is also used by the Illinois State Association for the Prevention of Tuberculosis.

4. The Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis (founded February, 1903). Dr. Lawrence F. Flick, medical director, 238 Pine Street, Philadelphia, Pa. This is one of the most completely equipped and most efficient establishments connected with the movement. The institute maintains a hospital for advanced cases, a free clinic, and a laboratory. It also arranges lectures and does other educational work. The results of its first year's work have been published in a report, containing statistics from about 2,000 cases treated.

5. The Boston Association for the Relief and Control of Tuberculosis (organized in 1903). Alexander M. Wilson, general secretary; 8 Beacon Street, Boston. This committee carries on educational and statistical work, promotes the establishment of sanatoria and hospitals, and has done much to arouse interest in the subject among trades unions.

There are similar societies or committees carrying on this work in the following cities: Hartford and New Haven, Conn.; Washington, D. C.; Lexington, Ky.; Peoria, Streator, Jacksonville and Moline, Ill.; Cambridge, Mass.; Minneapolis; St. Louis; Binghampton, Buffalo and Rochester, N. Y.; Cleveland, Toledo and Youngstown, Ohio; Scranton, Pa.; Newport, R. I.

Among the most important state organizations are the following:

The Pennsylvania Society for the Prevention of Tuberculosis (organized in 1892). The first state society of its kind in America. It has done much educational and legislative work, and has agitated for better sanitary conditions.

The Tuberculosis Commission of Maryland has made an extensive study of tuberculosis in Maryland, embodying the results in a report to the governor of the state, published in 1904. It also held a tuberculosis exposition in Baltimore, in January, 1904, which greatly increased interest in and knowledge of the subject.

The Illinois State Association for the Prevention of Tuberculosis (organized in January, 1905), has prepared and distributed literature, and has organized the work against tuberculosis in a number of towns. The association has also conducted a vigorous campaign for the establishment of a state sanatorium.

There are also state associations, committees or commissions in the following states: California, Georgia, Indiana, Iowa, Kentucky, Minnesota, New Hampshire, New Jersey, Ohio, Vermont and Wisconsin.

Among the more valuable works on the subject are these: "A Directory of Institutions and Societies Dealing with Tuberculosis." Charity Organization Society, New York, 1904. "A Handbook on the Prevention of Tuberculosis," Tuberculosis Committee of Charity Organization Society, N. Y., 1904. "First Annual Report of the Henry Phipps Institute." Philadelphia, 1905.

A complete list of all organizations, hospitals, dispensaries, etc., for tuberculosis was given in The Journal, Feb. 11, 1905, page 455.

State Boards of Registration

COMING EXAMINATIONS.

Wyoming Board of Medical Examiners, Cheyenne, December 6. Secretary, S. B. Miller, Laramie.

Examining Board representing the President and Fellows of the Medical Society of Delaware at Dover, and the Homeopathic Board, Wilmington, December 12. Secretary, P. W. Tomlinson, Wilmington.

Ohio State Board of Medical Registration and Examination, Columbus, December 12-14. Secretary, F. Winders, Columbus.

Medical Examining Board of Virginia, Richmond, December 12-15. Secretary, R. S. Martin, Stuart.

Board of Medical Examiners of Maryland, Baltimore, December 13-16. Secretary, J. McScott, Hagerstown.

State Board of Health of Missouri, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

Board of Medical Examiners State of California, San Francisco, December 20. Secretary, Charles L. Tisdale, San Francisco.

Colorado March, July and October Reports.—Dr. S. D. Van Meter, secretary of the Colorado State Board of Medical Examiners, reports the oral and written examinations held at Denver, March, July and October, 1905.

At the March examination the number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 70. At the July and October examinations the number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 70.

At the March examination the total number of candidates examined was 3, of whom 2 passed and 1 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Physio-Medico College, Chicago	(1900)	70
College of Medicine and Surgery, Chicago	(1904)	78

FAILED.

College.	Year. Grad.	Per Cent.
Little Rock and Dallas, Texas, Med. Coll		31.9

At the July examination the total number of candidates was 4, including one osteopath. Two passed, 1 failed, and 1 failed to appear for examination.

PASSED.

College.	Year. Grad.	Per Cent.
Barnes Med. Coll., St. Louis	(1905)	70

FAILED.

Kansas Med. Coll. (1895)*
California Med. Coll. (1904)**

* Candidate took the oral and clinical examination, but refused to take the written one.

** Candidate failed to appear for examination. License refused.

At the October examination one candidate, a graduate of Starling Medical College (1855), took the oral and clinical examination, but refused to take the written one, and a license, therefore, was refused. A graduate of the College of Medicine and Surgery, Indianapolis (1894), applied for license but refused to appear for examination; in this case also the license was refused. A license was refused to one candidate on account of his moral character.

From April 20 to October 1 there were thirty applicants, not included in refused list, who have not been granted licenses, owing to the fact that after filing their preliminary papers they either failed to complete their applications or withdrew them. Some of these candidates failed to appear for legitimate reasons, such as changing their minds, etc., but the majority did so because they concluded after further investigation that they would be refused licenses. This explains why the percentage of refused applicants and written examinations is so low.

Iowa Requirements.—At the semi-annual meeting, November 1, the Iowa State Board of Medical Examiners ruled that, after July 1, 1906, they will consider no medical college in good standing which does not require as a condition for graduation not less than four courses of lectures of not less than seven months each, no two of which shall begin or end in the same calendar year; or which grants any advanced standing because of the possession of a literary or scientific degree. Graduates of colleges which do not fulfill the requirements will not be examined.

Idaho October Report.—Dr. J. L. Conant, Jr., secretary of the Idaho State Board of Medical Examiners, reports the written examination held at Boise, Oct. 3-4, 1905. The number of subjects examined in was 13; total number of questions asked, 110; percentage required to pass, 75. The number of candidates examined was 31, of whom 27 passed and 4 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Rush Med. Coll.,	(1880) 83.8; (1890) 82.8; (1902) 75; (1905)	93.3
Washington University. St. Louis	(1905)	84.8
	(1904) 83.1; (1905) 78.4,	81.8
Jefferson Med. Coll.	(1887)	77.9
University of Minnesota	(1901)	79.5
Hahnemann Med. Coll., Chicago	(1903)	80.9
University Med. Coll., Kansas City	(1904)	86.3
Kansas City Med. Coll.	(1904)	84.5
University of Michigan	(1905)	81.5
Central Med. Coll.	(1897)	77.5
University of Iowa, Homeo. Dept.	(1905)	80.3
Northwestern University	(1904) 80; (1905)	83.2
University of Colorado	(1905)	85.9
Kansas Med. Coll.	(1904)	78.4
University of the South, Sewanee	(1904)	87
Herring Med. Coll., Chicago	(1903)	75
University of Nebraska	(1892)	79.3
Kentucky School of Medicine	(1905)	88
University of Toronto	(1904) 81.2, 87.3	88.2
Denver & Gross Coll. of Med.		

FAILED.

College.	Year. Grad.	Per Cent.
Ft. Wayne Med. Coll.	(1892)	73.6
University of Michigan	(1901)	72.3
University of Louisville	(1883)	38
Bennett Med. Coll., Chicago	(1900)	68.2

Oregon April Report.—Dr. B. E. Miller, secretary of the Board of Medical Examiners of the state of Oregon, reports the written examination held at Portland, April 20, 1905. The number of subjects examined in was 15; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 54, of whom 28 passed and 26 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
University of Oregon	(1905) 75.3, 79, 79.40, 79.8, 79.8, 80.8, 81, 81, 81, 81.5, 82.9, 84, 86.6,	86.7.
Willamette University	(1905) 78.6, 79,4, 79.4, 81.3,	83.4
College of P. and S., San Francisco	(1904)	84.6
Rush Med. Coll	(1895) 81.8; (1897)	80.8
Woman's Med. Coll., Pennsylvania	(1904)	88.4
University of Nashville	(1896)	76.6
University of Baltimore	(1899)	82.2
University of Michigan	(1885)	87.2
College of Med. and Sur., Minn	(1901)	81.8

FAILED.

College.	Year. Grad.	Per Cent.
Medico-Chirurgical College, Missouri	(1905)	69
Marion-Sims-Beaumont Coll., Missouri	(1904)	71
Marion-Sims Med. Coll.	(1891)	69
Illinois Med. Coll.	(1892)	71.8
Rush Med. Coll.	(1892)	71.8
American Coll. of Med. and Surg., Illinois	(1904)	51.6
California Med. Coll.	(1902)	71
Dallas Med. Coll., Texas	(1904)	31.5
Hahnemann Med. Coll. Hosp., California	(1897)	30.9
University of Oregon	(1905) 71, 74, 74, 74, 74, 74.8, 74.8, 74.4, 74.5, 71.2, 71, 71,	71.
Willamette University	(1905) 74.7, 72.4,	73
Nongraduates	71,	56.2

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending November 25:

Hoff, John Van R[illegible]al, ordered to report in person to the chief [illegible] duty in his office.

DeWitt, Wallace, a[illegible]bsence extended ten days.

Frick, Euclid B., [illegible] accompany troops G and H, Third Cavalry, f[illegible]nn., to San Francisco.

Collins, C. C., ass[illegible], granted thirty days' leave of absence, with permission to apply for thirty days' extension.

Lippitt, Wm. F., surgeon, granted four months' leave of absence.

Rockhill, E. P., asst.-surgeon, ordered to report to Lieut.-Col. Geo. H. Torney, deputy surgeon general, president, examining board, General Hospital, Presidio of San Francisco, for examination to determine his fitness for advancement, on December 29.

Metcalfe, R. F., asst.-surgeon, ordered, on arrival at San Francisco, to proceed to Fort Leavenworth, Kan., for temporary duty. On return of Asst.-Surgeon Buck to that post, Asst.-Surgeon Metcalfe will proceed to Columbus Barracks, Ohio, for station.

Lippitt, Wm. F., surgeon, granted leave of absence from December 19, 1905, to January 5, 1906.

Owen, Wm. O., surgeon, having been found by an army retiring board incapacitated for active service on account of disability incidental thereto, his retirement from active service by the President, November 23, is announced.

Koerper, C. E., asst.-surgeon, in addition to his present duties will report at Washington Barracks, D. C., for temporary duty.

Havard, Valery, asst.-surgeon general, left Governor's Island, N. Y., with department commander on inspection tour.

Raymond, Henry I., surgeon, left Columbus Barracks, Ohio, with recruits to Vancouver Barracks, Washington.

Farrow, Edgar J., contract surgeon, ordered to sail for Manila, P. I., November 25, for duty in the Philippines Division.

Hereford, John R., contract surgeon, granted an extension of one month to his leave of absence.

Wing, Franklin F., dental surgeon left Fort Des Moines, Iowa, and arrived at Jefferson Barracks, Mo., for duty.

Carpenter, Alden, dental surgeon, left Boise Barracks, Idaho, for Vancouver Barracks, Washington, his proper station.

Daywalt, George W., contract surgeon, left Fort St. Philip, La., on leave of absence for one month, twelve days.

Mason, George L., dental surgeon, ordered from Fort McPherson, Ga., to Fort Fremont, S. C., for two weeks' duty; to go thence to Fort Moultrie, S. C., for one month.

Wolven, F. Homer, dental surgeon, granted leave of absence for fifteen days.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending November 25:

Guthrie, J. A., surgeon, orders of November 8, modified; granted sick leave for three months.

Ledbetter, R. E., P. A. surgeon, detached from the Navy Yard, Norfolk, Va., and ordered to the *Glacier*.

Traynor, J. P., asst.-surgeon, ordered to the Naval Hospital, Boston.

Miller, J., asst.-surgeon, detached from the *Lawton* and ordered to duty at Midway Islands.

Hart, G. G., acting asst. surgeon, detached from the *Glacier* and ordered to the naval recruiting station, Buffalo, N. Y.

Tyree, F. W., acting asst-surgeon, detached from duty at Midway Islands and ordered to duty at the naval training station, San Francisco.

Evans, S. G., surgeon, ordered to the naval recruiting rendezvous, Denver, December 1.

Miller, J. T., acting asst.-surgeon, detached from the naval hospital, Sitka, Alaska, and ordered home to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 22:

Vaughan, George T., assistant surgeon-general, granted leave of absence for four days from November 15.

Bailhache, P. H., surgeon, granted leave of absence for ten days from November 20.

Sawtelle, H. W., surgeon, granted extension leave of absence for twenty days, from November 23.

McIntosh, W. P., surgeon, twenty-one days leave of absence granted from November 15, amended to read twenty-one days from November 18.

Rosenau, M. J., P. A. surgeon, granted leave of absence for fourteen days from November 22.

Parker, H. B., P. A. surgeon, granted leave of absence for twenty days from December 15.

Anderson, J. F., P. A. surgeon, leave of absence granted for one month from November 1, amended to read eighteen days from November 1.

Corput, G. M., P. A. surgeon, directed to proceed to Pascagoula, Miss., for special temporary duty.

Berry, T. D., P. A. surgeon, leave of absence temporarily revoked and directed to proceed to Biloxi, Miss., for special temporary duty.

Warren, B. S., P. A. surgeon, granted extension leave of absence for one month from December 3.

Bahrenburg, L. P. H., Burkhalter, J. T., and Boggess, J. S., asst.-surgeons, to report to chairman of board of examiners at Washington, D. C., December 4, for examination to determine their fitness for promotion to the grade of passed assistant surgeon; on completion of this duty to rejoin station.

Jackson, J. M., acting asst.-surgeon, granted six days' leave of absence, from November 5.

Mohr, H. B., acting asst.-surgeon, granted leave of absence for thirty days, from December 1.

Small, E. M., acting asst.-surgeon, granted leave of absence for fourteen days beginning December 7.

Frick, John, acting asst.-surgeon, granted leave of absence for thirty days, from December 1.

Kennard, Karl S., acting asst surgeon, granted leave of absence for fourteen days, from November 27.

Stearns, H. H., acting asst.-surgeon, granted leave of absence for twenty-one days from Dec. 11, 1905.

Tarbell, B. S., acting asst.-surgeon, granted leave of absence for ten days from November 21.

Richardson, S. W., pharmacist, granted leave of absence for twenty-three days from November 23.

BOARD CONVENED.

Board to meet at Washington, D. C., December 4, for the examination of assistant surgeons. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman: Assistant Surgeon-General J. M. Eager; P. A. Surgeon John F. Anderson, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the surgeon general, Public Health and Marine-Hospital Service during the week ended November 20.

SMALLPOX—UNITED STATES.

[illegible]cisco, Oct. 29-Nov. 11, 7 cases.
[illegible] Nov. 4-11, 1 case.
[illegible]: New Orleans, Nov. 4-11, 2 cases.
Michigan: [illegible] Nov. 4-11, 4 cases.
O[illegible] Nov. 11-18, 5 cases.
P[illegible] Nov. 11-18, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Aug. 1-31, 28 deaths.

Brazil: Bahia, Oct. 1-21, 117 cases, 3 deaths; Pernambuco, Sept. 17-30, 208 deaths; Rio de Janeiro, Oct. 8-15, 6 cases, 6 deaths.

Canada, Toronto, Nov. 4-11, 5 cases.

England, Leeds, Oct. 29-Nov. 4, 1 case; Nottingham, Oct. 14-21, 1 case.

France: Paris, Oct. 21-28, 8 cases.

Gibraltar: Oct. 29-Nov. 4, 4 cases.

India: Bombay, Oct. 10-17, 2 deaths.

Italy: Catania, Oct. 28-Nov. 2, 2 cases; Genzano, 2 cases; Magliano Dei Marti, 1 case; Messina, Oct. 21-28, 1 death; Troina, Oct. 28-Nov. 2, 2 cases; Vallelonga, 2 cases.

Russia: Moscow, Sept. 23-Oct. 14, 16 cases, 10 deaths; Odessa, Oct. 14-21, 9 cases; St. Petersburg, Oct. 1-21, 5 cases.

Spain: Barcelona, Oct. 21-31, 3 deaths.

Turkey: Constantinople, Oct. 22-29, 2 deaths.

YELLOW FEVER—UNITED STATES.

Florida: Pensacola, Nov. 9-16, 1 case, 1 death.

Louisiana: New Orleans, Nov. 4-11, 2 cases, 1 death.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Oct. 8-15, 2 deaths.

Honduras: Choloma, Nov. 15, present; Puerto Cortez, 2 cases; San Pedro, 3 cases.

Mexico: Vera Cruz, Oct. 29-Nov. 4, 2 cases, 1 death.

CHOLERA—FOREIGN.

Germany: Kurzebrack, Sept. 3-9, 4 cases, 2 deaths; Adolfsdorf, Sept. 1-Oct. 14, 12 cases, 2 deaths; Czarnikkau, to Sept. 2, 2 cases, 2 deaths; Dratzig, Sept. 3-9, 3 cases, 3 deaths; Grandenz, to Sept. 9, 8 cases, 2 deaths; Gnesen, Sept. 3 9, 3 cases; Rastenburg, 1 case; Sommerau, 1 case, 1 death; Steinfurth, Sept. 1-7, 1 case; Warnikeim, Sept. 10-16, 1 case, 1 death; Stolpe, Oct. 1-21, 19 cases, 1 death; Strasburg, Oct. 15-21, 1 case.

India: Calcutta, Sept. 23-Oct. 14, 127 cases.

Russia: Vistula Territory, Oct. 11-18, 26 cases, 14 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 1-31, 7 deaths.

PLAGUE—FOREIGN.

Australia: Sydney, Aug. 1-31, 1 death.

Brazil: Rio de Janeiro, Oct. 8-15, 5 deaths.

India: General, Oct. 7-14, 4,294 cases, 3,395 deaths; Bengal, 88 cases, 65 deaths; Bombay, Oct. 10-17, 14 deaths; Calcutta, Sept. 23-Oct. 14, 26 deaths; Karachi, Oct. 10-17, 10 cases, 8 deaths.

Japan: Kobe, Oct. 14-21, 2 cases, 2 deaths.

Peru; Lima, Oct. 11-20, 7 cases, 4 deaths; Sept. 21-30, 4 cases, 2 deaths; Payta, Oct. 11-20, 1 case, 1 death, Sept. 21-30, 3 cases, 2 deaths; Mausiche, 3 cases.

Medical Organization

California.

Alameda County Medical Association.—Dr. J. N. McCormack, organizer for the American Medical Association, delivered an address before the Alameda County Medical Association, October 18, in which he urged the benefits of organization.

Long Beach Medical Society.—The medical fraternity of Long Beach assembled, October 27, to meet Dr. J. N. McCormack, organizer of the American Medical Association, and Dr. Philip Mills Jones, San Francisco, secretary of the State Board of Health, with the object of effecting a local organization. After addresses by the visitors, an organization was formed, with Dr. Homer O. Bate, president, and Dr. Joseph M. Holden, secretary.

Northern California Medical Association.—This association completed its organization at Redding, October 23, by electing the following officers: Dr. Clarence E. Reed, Redding, president; Dr. Thomas J. Edgecomb, Shasta, vice-president; Dr. Robert F. Wallace, Redding, secretary and treasurer; Drs. Sherman T. White, Redding, Robert T. Legge, Siskiyou, and Lucian A. Bauter, Redding, executive committee, and Drs. Ferdinand Stabel, Redding, and George E. Flora, Igo, finance committee.

Georgia.

Elbert County Medical Society.—The physicians of Elbert County met at Elberton, November 15, to discuss the organization of a county medical society.

Georgia Medical—Chatham County Medical Society.—At a joint meeting of the Georgia Medical Society and the Chatham County Medical Society, held in Savannah, October 27, preliminary measures were taken to amalgamate the two societies, in conformity with a resolution passed at the last annual meeting of the state medical association, providing for one society in each county. The meeting was called by Dr. John S. Howkins, Savannah, councilor of the First District, who presided, and Dr. Martin J. Cooley, Savannah, acted as temporary secretary. A constitution and by-laws were adopted as prescribed by the American Medical Association.

Meriwether County Medical Society.—The physicians of this county met in Greenville, October 18, and organized a county medical organization, with the following officers: Dr. Edward B. Terrell, Greenville, president; Dr. Jesse S. Snead, St. Marks, vice-president; Dr. Pryor W. Fitts, Greenville, secretary and treasurer, and Drs. John W. Pinkston, Greenville, F. H. Letson, Lone Oak, and Charles E. Stipe, Odessadale, *censors.*

South Georgia Medical Association.—This association was organized at Cordele, November 1, under the auspices of the Georgia Medical Association, with the aid of Dr. R. E. Lee Barnum, Richland, councilor for the third congressional district, with 15 charter members. The following officers were elected: President, Dr. J. T. Gammage, Pine View; vice-president, Dr. Archie Griffin, Luke; secretary and treasurer, Dr. Thomas J. McArthur, Cordele, and Drs. Virgie O. Harvard, Arabi, James A. Ward, Cordele, and L. A. Williams, Abbeville, censors.

Ware County Medical Association.—This association was re-organized at Waycross, October 20, on the standard plan. Dr. Jefferson D. Herrman, Eastman, councilor for the eleventh district, was present. Dr. Robert P. Izlar, Waycross, was elected president; Dr. James C. Rippard, Waycross, vice-president; Dr. H. M. Johnson, Waresboro, secretary, and Dr. F. C. Folks, delegate to the state association.

Pennsylvania.

Lawrence County Medical Society.—At its meeting, October 5, the standard constitution and by-laws was put in effect by this society.

Luzerne County Medical Society.—At a meeting of this society, October 5, Dr. Fell reported on the recent meeting of the state medical society in Scranton and gave a draft of the proposed new by-laws, which provide that any reputable physician, regardless of his school of medicine, is eligible for membership in the state and county societies, provided he carry on his work as a general practitioner and agree to practice nonsectarian medicine.

Dr. McCormack's Tour.

The Texas meetings have proved to be very successful, some of them the largest ever held in Texas. At many of the meetings there were present, in addition to the physicians, a good representation of teachers, lawyers, legislators, preachers and druggists.

Some of his meetings were as follows: Galveston, November 6; Houston, November 7; Waco, November 8; Fort Worth, November 10; Dallas, November 13; Tyler, November 15; Paris, November 17; Bonham, November 20, and Gainesville, November 23.

As the strongest arguments for organization Dr. McCormack detailed the benefits to the profession and to the laity that would be sure to follow. He compared the general pleasant relations among lawyers with traditional discord among doctors. The lawyers are on good terms because they are frequently closely associated in court and become well acquainted in the ordinary course of their professional work. Physicians work in isolation and must create for themselves the needed opportunity for mingling—the county medical society. Mutual acquaintance paves the way for the co-operation that is essential to the profession if it is to accomplish the great things for which its knowledge fits it. Postgraduate study was urged on every physician as indispensable to real success. Physicians and laity should support the anti-nostrum crusade so well begun by prominent lay journals. [In this connection Dr. McCormack writes that a surprisingly large number of country papers are republishing the *Collier's* exposures and delaring their independence of the now notorious "red clause."]

From Dallas, Texas, there comes news that Dr. McCormack's appeals have already borne fruit. It is announced that joint meetings will be held of the physicians with, first, the lawyers (to discuss legislation and medical testimony), and second, with the clergy, for the purpose of arranging for co-operation in efforts to improve social conditions.

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

BOSTON MEDICAL LIBRARY MEETING.

Regular Meeting, held Nov. 15, 1905.

Dr. Richard C. Cabot in the Chair.

The purpose of the meeting was to demonstrate the practical usefulness of "moving pictures" in teaching students or illustrating medical subjects.

Dr. Walter B. Chase of Brookline told of the rapid developments of this work during the past few years and of his own application of it. He demonstrated the special camera needed, the films, etc., and explained how they are prepared. He has taken in this way about 37,000 pictures, of which 22,000 are of epileptic seizures, including all classes of cases, even the "status epilepticus." They were taken at the Craig Epileptic Colony at Sonyea, N. Y. Other pictures shown by the biograph were athetosis, rhythmic idiots, nystagmus and a variety of gaits. He believes that soon it will be possible to show the heart beating, and the pupil of the eye dilating and contracting.

Dr. W. B. Cannon demonstrated, also by the biograph, the movements of the stomach and intestines. These pictures were obtained by the *x*-ray fluoroscope, the food having been impregnated with bismuth subnitrate. Outline pictures were traced successively and photographed on the biograph film. The results as thrown on the screen clearly showed the waves of motion near the pylorus of the stomach and the quiet at the cardiac end. The latter suggests an opportunity for the salivary digestion. In the small intestine he showed that peristalsis is less frequent than "rhythmic segmentation." In the upper part of the large intestine, close to the ileocecal valve, a distinct anti-peristalsis was demonstrated—the last effort of the digestive tract to separate nutriment from the food.

Dr. R. C. Cabot demonstrated five pictures of pyopneumothorax. The camera was located directly over the cadaver, and photographs were taken as the autopsy progressed while the organs were *in situ*, the photographs being colored to accord with the actual specimens. One unique fact thus made prominent was that in left-sided effusion the entire mediastinum is pushed to the right, the relative position of the heart being maintained.

SOUTHWESTERN TRI-STATE MEDICAL ASSOCIATION OF TEXAS, OKLAHOMA AND INDIAN TERRITORY.

Sixth Annual Session, held in Oklahoma City, Nov. 8-9, 1905.

The President, Dr. W. R. Blailock, Dallas, Tex., in the Chair.

Welcome.

The address of welcome on behalf of Oklahoma City was delivered by the Hon. B. M. Dilly, in place of Mayor Messenbaugh, who was unable to be present. Dr. Vene P. Armstrong, Dallas, Texas, responded. Dr. William T. Salmon, Oklahoma City, welcomed the visitors in behalf of the medical profession, and to this address Dr. James C. Loggins, Ennis, responded. President T. D. Turner, of the Chamber of Commerce, then welcomed the association in the name of that body and extended an invitation for a car ride.

Treatment of Insane.

Dr. John S. Turner, Terrell, Texas, in a paper entitled "Therapeutics Employed in the Treatment of the Insane," referred to the false economy of commonwealths in the profession for the insane and especially in the way of cottage treatment. He urged the great need of the proper transfer of nervous patients to reliable and reputable sanatoria for skilled treatment and proper feeding. He strongly commended care in feeding insane patients and urged the advantage of natural sleep over that induced by narcotics. He declared it often to be absolutely necessary that friends and relatives be kept away from patients.

Mental Responsibility.

Hon. B. F. Burwell, Oklahoma City, in his address on this subject, urged that physicians and surgeons make a special study of insanity in order that when they are called into court to offer expert testimony they may be qualified so to act. The problem of whether or not an individual committing a crime is mentally responsible is one of the greatest importance in the trial of criminal cases, as insanity is so often made the defense. The speaker urged physicians so to prepare themselves that they might be able to determine whether or not in any given case the defendant was insane and, if necessary, the extent of the mental alienation.

Division of the Fee.

A warm discussion arose during the discussion on the division of fees. It was found to be the consensus of opinion of those present that there should be no secret in such cases, and that the honorable course is to present separately the bill of the specialist and that of the physician who brings the patient to him. Such a course would remove from the patient any suspicion of unfair dealing.

Banquet.

The banquet held at the Threadgill was attended by 110 members, and Dr. A. De Bord Young, Oklahoma City, acted as toastmaster.

Election of Officers.

The following officers were elected: President, Dr. George W. West, Eufaula, I. T.; vice-presidents, Drs. Edward H. Troy, South McAlester, I. T.; Richard T. Edwards, Oklahoma City, Okla., and George H. Moody, San Antonio, Texas; secretary and treasurer, Dr. Rufus J. Crabill, Allen, I. T.; chairman of section on surgery, Dr. Charles M. Rosser, Dallas, Texas; materia medica and therapeutics, Dr. Mahlon A. Kelso, Enid, Okla.; eye, ear, nose and throat, Dr. L. Haynes Buxton, Oklahoma City, Okla.; state, medical and public hygiene, Dr. Arthur L. Anderson, Wilburton, I. T.; practice of medicine, Dr. Warren F. West, Waxahachie, Texas; diseases of children, Dr. U. A. D. Callamo, Coalgate, I. T., and obstetrics and gynecology, Dr. William B. Pigg, South McAlester.

South McAlester was selected as the next place of meeting, on Oct. 16 and 17, 1906.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Colic.

In making a diagnosis of colic, several things which may cause pain should be considered. According to Hutchison, whenever an infant screams almost constantly the possibility of colic should be thought of. Other causes for such outbursts may cause a mistake in the diagnosis. One of these is earache, another is teething, and there are still others, such as renal colic, phimosis, and tenderness of bones, as in scurvy. One of the signs, also, of defective cerebral development in young infants is screaming without any apparent cause. Colic, however, is commoner than all the other causes put together. The important signs of colic are hardness of the abdomen, the tendency to draw up the legs, and perhaps convulsions. When there is passage of flatus there is a cessation of screaming for a time, and this latter is the most positive symptom of colic.

In the treatment of an attack of colic, the first thing to be done, according to Hutchison, is to apply warmth to the abdomen. This can be done by means of friction with warm oil, by warm fomentations or by poultices of linseed or mustard; in extreme cases the mustard bath may be used. In addition to the external application of warmth, it can be applied internally by means of enemas of warm water. Two or three ounces of water should be injected as hot as the child can bear it; an effort should be made to reach as much of the large intestine as possible.

Carminatives should be given by the mouth in order to aid in the expulsion of flatus. Peppermint water and dill water are both suitable for this purpose. Ten drops (.65) of spiritus etheris nitrosi (sweet spirits of nitre) is also recommended and preferred by some authorities. Such measures as the foregoing, according to Hutchison, are usually effective in cutting short an attack of colic.

The next question to consider is how to prevent the recurrence of the attack. The author divides the cases into two groups: Infants that are breastfed and those which are bottlefed. Inquiry will usually show that the breastfed infant is nursed too frequently and often at irregular intervals. In such cases the simple regulation of nursing suffices. The time between the feedings should usually be lengthened. The mother is inclined to overfeed the child, because of the temporary relief afforded by the warm milk in the child's stomach, which, however, is frequently followed by a severe attack of colic, and in this way a vicious circle is formed. The clock should be brought into use in such cases to correct the irregular intervals between feedings. The presence of too much casein is responsible for the attacks in a great many cases. When such is the case, the administration of a few teaspoonfuls of lime water before each feeding is of advantage; it should be sweetened slightly to make it more palatable for the child. If the infant is constipated, as is so often the case in breast-fed children, this condition should by all means be corrected. On the other hand, bottle-fed infants are troubled with diarrhea, which must be corrected.

In the treatment of the constipation, a drastic cathartic, such as a large dose of castor oil at irregular intervals, should never be given. Massage should be applied to the abdominal muscles over the course of the colon, twice a day, morning and evening, for five or ten minutes at a time.

In the use of medicines to correct constipation, only those should be selected which have a tonic action on the coats of the intestine. To meet these indications, the following combination is recommended by the author:

℞.	Tinct. aloes	gtt. iii-v		20-.30
	Syrupi sennæ	gtt. xx	1	30
	Tinct. belladonnæ	gtt. ii		12
	Tinct. nucis vomicæ	gtt. ss		03
	Infusi gentianæ co. q. s. ad	ʒi	4	

M. Sig.: To be taken at one dose as a laxative.

The size of the dose should depend on the age of the child. The author recommends the addition of dill water, cinnamon water or peppermint water to the foregoing, if necessary to modify the taste and as a carminative.. In mild cases it may be necessary to give only one dose of the foregoing at night; in other cases it may be necessary to give it at regular intervals two or three times a day until the action of the bowels takes place at regular intervals, after which the medicine should be gradually discontinued.

If for any reason the foregoing combination does not meet the requirements of the case, or if vomiting is produced on account of the bitter taste, the confection of sulphur is recommended, giving half a teaspoonful (200) at night, or both morning and night, as infants will take it very readily. If, after correcting constipation, the colic persists and the child is losing weight, the question of changing the food should be considered.

In the prevention of colic in bottle-fed infants, cleanliness in preparing the milk is frequently wanting, in addition to the conditions already mentioned.

In all cases of colic, carminatives administered between the feedings are recommended by Hutchison. The carminative should contain certain definite ingredients and should be alkaline in reaction. For this purpose he recommends the following combination:

℞.	Sodii bicarb.	gr. iiss		15
	Spts. ammon. arom., āā	gtt. iiss		15
	Glycerini	m. ii		12
	Aq. menthæ piperitæ q. s. ad	ʒi	4	

M. Sig.: To be given to the infant at one dose, and repeated as necessary between the feedings.

The glycerin is preferred to syrup to render the taste pleasant on account of the liability of the latter to ferment. In addition to keeping the child warm, if it gains weight, one is perhaps not justified in producing too great an alteration in the food. Under such circumstances, opium in some form is recommended. The best preparation, according to this author, is codein given in doses of grain 1/40 to 1/30 (.0015-.0020), combined with glycerin and peppermint water. [While Hutchison recommends this dosage, it should be remembered that children are susceptible to opiates, and that it might be advisable to start with a smaller dose.] A combination similar to the following is recommended by some authors to relieve the colic of infants:

℞.	Spts. etheris comp.			
	Aq. camphoræ, āā	ʒii	8	
	Aq. menthæ viridis	ʒiv	15	
	Aq. dest.	ʒiii	12	

M. Sig.: One teaspoonful every two or three hours, to a child 2 or 3 years of age. Or:

℞.	Tincture opii camph.	gtt. xl	2	65
	Essentiæ feniculi	m. iv		15
	Syrupi zinziberis q. s. ad	℥ii	60	

M. Sig.: Fifteen to thirty drops in water every two hours to children under one year of age.

Psoriasis.

As an internal remedy in the treatment of psoriasis, the following combination is recommended by *Merck's Archives*:

℞.	Sulphuris precipitatæ	gr. iii		20
	Salol	gr. ii		12
	Olei gaultheriæ	m. ss		03
	Acidi arsenosi	gr. 1/30		002

M. Ft. capsula No. i. Sig.: One such capsule three times a day for an adult.

Sulphur in the Treatment of Chronic Nasal Catarrhs.

Kolipinski, in *Med. News*, states that sulphur is valuable in the treatment of simple chronic rhinitis, in the hypertrophic stage. Intumescent rhinitis is relieved by this preparation, but its effects in atrophic rhinitis are not so effective as during the earlier stages. In phlegmonous rhinitis the disease is often aborted by it. Scrofulous rhinitis, he says, can also be improved by its application. The immediate effects of sulphur are to check the purulent irritating discharge, to heal the excoriations, to improve the patient's pale and languid appearance and to stop the sniffling, sneezing, crust formation and odor. In epistaxis from any cause this is regarded by the author as one of the best preparations, but should be reinforced for twenty-four hours with a gauze tampon. It is a splendid postoperative dressing in surgery of the nasal cavities. The best preparation is the official sulphur precipitatum, United States Pharmacopeia. In the treatment of rhinitis, applications of sulphur should be made to the nares two or three times a week for one month, and then less frequently. It should be insufflated into the nares by means of an ordinary powder blower.

Treatment of Roentgen Ray Burns.

Engman, in an article in the *Ther. Gazette*, recommends, in the treatment of burns from the Roentgen ray, that the exposures be discontinued and lanolin applied for twenty-four hours, after which the following combination is recommended:

℞.	Acidi borici	℥iss	45
	Zinci oxidi		
	Bismuthi subnit.		
	Pulv. amyli, āā	℥i	30
	Olei olivæ		
	Aquæ calcis		
	Lanolini, āā	℥iii	90
	Aquæ rosæ	℥iss	45

M. Ft. unguentum. Sig.: Apply localy to the affected areas.

Satterlee, in the same periodical, recommends the following combination in the treatment of this condition:

℞.	Acidi carbolici	ʒiv	15
	Aquæ rosæ	℥iv	120

M. Ft. solutio. Sig.: Apply locally.

Tuberculous Glands.

The following combination is recommended by Thornton, in Denver *Medical Times*, in the treatment of tuberculous glands:

℞.	Syr. ferri iodidi	m. v		30
	Olei morrhuæ	m. xx	1	30
	Ext. pancreati	gr. i		06

M. Ft. cap. No. i. Sig.: One or two such capsules two hours after each meal.

E. P. Davis recommends, in addition to tonics, the following combination as an ointment:

℞.	Ichthyol	gr. x		65
	Ung. zinci oxidi			
	Lanolini, āā	ʒii	8	

M. Ft. unguentum. Sig.: Apply locally night and morning.

Suprarenal Extract in Asthma.

Dr. G. W. Kirby, Millersburg, Ind., calls attention to the marked opportunity before the physician to fulfill his high aim of relieving suffering and of prolonging life by relieving the intense suffering produced by a severe asthmatic attack. He declares that more rapid relief can not be obtained in any condition than that secured in the use of the blood-raising principle from the suprarenal gland. He injects subcutaneously from 8 to 15 drops of adrenalin, which has been diluted with an equal amount of sterile water. This affords the patient almost instant relief. Aside from a throbbing sensation in the head and a weakness of the limbs due to the stimulation of the heart, no bad results follow. To my knowledge, he continues, this drug has not been advertised to be used in this condition, nor have I known of its general use in practice. It gives some relief in every case, but its chief use can be considered specific in the treatment of the spasmodic form of asthma, where so much morphia is given.

Medicolegal

To Prevent the Buying and Selling of Infant Children.

No. 154 of the Laws of Pennsylvania of 1905 provides that if any person or persons shall, within that state, trade, barter, buy, sell, or deal in humanity, by trading, bartering, buying, selling, or dealing in infant children, he, she, or they shall be guilty of a misdemeanor, and on conviction thereof shall be sentenced to pay a fine not exceeding $1,000, or undergo an imprisonment not exceeding five years, or both, at the discretion of the court.

Use of Preservatives in Food Products.

No. 7 of the Public Acts of Michigan of 1905 provides that no person, firm or corporation shall manufacture, sell, offer for sale, expose for sale, or have in his possession with intent to sell, any food product containing benzoic acid or benzoate of sodium, or any other harmless preservative, unless each and every package containing the same shall, in the condition in which it is exposed for sale, be distinctly, conspicuously and legibly branded, labeled or marked, in plain English letters, with the words "prepared with" followed by the proper English name of the preservative used; provided, that nothing in this act shall be construed to prohibit or regulate, by branding or otherwise, the use as a preservative of common salt, syrup, sugar, saltpetre, spices, alcohol, vinegar or wood smoke; and provided, further, that the provisions of this act shall not apply to dairy products.

New Grounds for Revoking Certificate.

No. 161 of the Public Acts of Michigan of 1905 amends the sixth division of section 3 of the medical practice act as amended in 1903 providing that the State Board of Registration in Medicine may revoke the certificate of registration, after due notice and hearing, of any registered practitioner for certain causes by adding thereto: "Or who for the purpose of procuring patients employs any solicitor, capper or drummer; or who shall subsidize any hotel or boarding house; or pay or present to any person money or other valuable gift for bringing patients to him."

No. 207 of the public acts of 1905 amends section 7 of said practice act by making the penalty for practicing medicine or surgery without a certificate of registration a fine of not more than $200, or imprisonment in the county jail for a period of not more than six months, or such fine and imprisonment, for each offense.

Restriction on Marriage.

Chapter 136 of the Public Acts of Michigan of 1905, in addition to retaining the prior provision that no insane person, idiot, or person who has been afflicted with syphilis or gonorrhea and has not been cured of same, shall be capable of contracting marriage, provides that no person who has been confined in any public institution or asylum as an epileptic, feeble-minded, imbecile or insane patient, shall be capable of contracting marriage without, before the issuance by the county clerk of the license to marry, filing in the office of the said county clerk a verified certificate from two regularly licensed physicians of the state that such person has been completely cured of such insanity, epilepsy, imbecility, or feeble-mindedness, and that there is no probability that such person will transmit any of such defects or disabilities to the issue of such marriage. Any person of sound mind who shall intermarry with such insane person or idiot or person who has been so confined as an epileptic, feeble-minded, imbecile or insane patient in any public institution or asylum, except on the filing of certificate as herein provided, with knowledge of the disability of such person, or who shall advise, aid, abet, cause, procure or assist in procuring any such marriage contrary to the provisions of this section, shall be deemed guilty of a felony and on conviction thereof shall be punished by a fine of not more than $1,000 or by imprisonment not less than one year nor more than five years, or by both such fine and imprisonment in the discretion of the court.

Provides for Sanatorium for Treatment of Tuberculosis.

No. 254 of the Public Acts of Michigan of 1905, an act to establish a state sanatorium in some suitable locality in Michigan, for the care and treatment of persons having tuberculosis, provides for a board of six trustees, four of whom shall be legally registered physicians, to be appointed by the governor. The trustees shall appoint a medical superintendent, not a member of the board, who shall be a legally qualified physician, of at least six years' experience in the practice of his profession, and who shall be chosen with a special view to his professional and executive ability. The medical superintendent, with the consent of the board of trustees, shall appoint such other officers, assistants and employes in and for the sanatorium as may be necessary, provided that all medical officers shall be well educated physicians. The medical superintendent shall be chief executive officer of the sanatorium. He or his representative shall daily ascertain the condition of each and all the patients, and prescribe or direct their treatment. There shall be received into the sanatorium such persons as shall be proved by proper bacteriologic or clinical examination to be suffering from tuberculosis. Such patients shall be of two classes, namely, first, persons resident of the state who on account of their poverty are unable to pay the necessary expenses for residence at the sanatorium; and, second, residents of the state who are able to pay such fees as shall be fixed by the board of trustees.

Provisions for Psychopathic Research.

No. 140 of the Public Acts of Michigan of 1905 provides that the joint board of trustees of the asylums for the insane of the state, in conjunction with the board of regents of the State University, shall select and employ from time to time an experienced investigator in clinical psychiatry, who shall be placed in charge of the psychopathic ward on the hospital grounds of the State University, and whose duty it shall be to conduct the clinical and pathologic investigations therein, to direct the treatment of such patients as are inmates of the psychopathic ward, to guide and direct the work of clinical and pathologic research in the several asylums of the state, and to instruct the students of the medical department of the university in diseases of the mind. In the conduct of this work he shall be allowed such graduate assistants as may be necessary and as the said board may approve. The said pathologist shall establish and maintain in said psychopathic ward a clinical laboratory of research in which investigations shall be continuously carried on with a view of determining the nature and causes of insanity and of perfecting the means of prevention and cure of diseases of this nature. Said pathologist shall make an annual report to the governor of the state on or before the first day of July of each year, of the medical work carried on at the psychopathic ward and in the clinical laboratory of research, and copies of such report shall be sent to the several boards of trustees of the various state asylums and to the board of regents of the State University. It shall be the privilege of the trustees of each public asylum of the state to have at any and all times at least one member of the medical staff of said asylum in the psychopathic laboratory of clinical research for special study, instruction and research.

To Secure Pure Foods.

Chapter 33 of the Laws of Wisconsin of 1905 makes it unlawful to manufacture, sell, ship, consign, offer for sale, expose for sale or have in possession with intent to sell for use or consumption within the state any article of food within the meaning of section 4600 of the statutes of 1898 and laws amendatory thereof (which would seem to make the term food include all articles used for food or drink), which contains formaldehyd, sulphurous acid or sulphites, boric acid or borates, salicylic acid or salicylates, saccharin, dulcin, glucin, beta naphthol, abrastol, asaprol, fluorids, fluoborates, fluosilicates or other fluorin compounds, or any other preservatives injurious to health; provided, however, that nothing contained in this section shall prohibit the use of common salt, saltpetre, wood smoke, sugar, vinegar and condimental preservatives, such as turmeric, mustard, pepper and other spices. Nor shall any article of food be manufactured, etc., containing an added substance, article or ingredient possessing a preservative character or action other than the articles named in the proviso of this act, unless the presence, name and proportionate amount of said added substance, article or ingredient shall be plainly disclosed to the purchaser.

Chapter 104 of the Laws of Wisconsin of 1905 amends section 4601a of the statutes of 1898 so as to make it unlawful to pack, can or preserve within the state, for use or consumption therein, fruits, vegetables, meats, fish or shellfish, or to sell, etc., for such use such canned articles containing saccharin, formaldehyd, sulphurous acid or sulphites, salicylic acid, or salicylates or any substance, article or ingredient other than sugar, salt, vinegar or spices, possessing a preservative character or action, or any copper compound or other artificial coloring, or any bleaching compound, or any article injurious to health.

Chapter 138 of the Laws of Wisconsin of 1905 prohibits the sale or delivery of adulterated milk or cream. Chapter 151 forbids the selling for maple sugar or maple syrup anything but the pure, unadulterated article. Chapter 152 is an act relating to the sale of syrups, molasses and glucose mixtures. Chapter 228 relates to the manufacture or sale of lemon extract and vanilla extract. Chapter 229 prohibits the sale of adulterated honey. Chapter 247 provides a standard for condensed milk and for evaporated cream.

6 Case of Anthrax—Probably Due to Inoculation—Without a Visible Initial Lesion. J. D. Jones, Utica, N. Y.

1. **Treatment of Advanced Cases of Pulmonary Tuberculosis.**—Knopf regards as advanced those cases of pulmonary tuberculosis that can no longer be classified as incipient or early. The advanced cases are divided into ambulant and bed cases. The former are those patients who are most of the time without fever, and in whom the systemic disturbances are only a little more aggravated than in the early stage. These cases may be treated as incipient, with the one exception, that if there is not a satisfactory gain in weight the patients should be put at rest in bed or on the reclining chair, constantly exposed to the open air. The ambulant patients are the most frequent sources of infection, and the greatest care must be taken to train them to dispose of their sputum properly. Several plans for accomplishing this are described. The bed cases are subdivided into four classes, namely, sanatorium patients, hospital patients, home patients—well-to-do, living either in cities or country—and the consumptive poor, living in villages or in city tenements. It is a matter of great difficulty to find proper accommodations for such patients, as sanatoria are usually unwilling to receive cases that do not offer a favorable prognosis. Knopf outlines the essentials for the institutional treatment of such patients, and then describes a great number of plans for applying the fresh-air principle in home treatment. One of the most serviceable of these, especially in dealing with the poor in cities, is a device invented by Knopf and known as the window tent. The patient lies on a cot, with his head beside the open window, to which is attached a sort of internal awning. This is arranged so that it shuts off the patient's head from the interior of the room, and permits the latter to be kept warm, while the effect is the same as if the patient were entirely out of doors. Other devices that are recommended are Bull's aërarium and Kellogg's *porte d'air*. These are intended to serve the same purpose of permitting the patient to remain indoors, while at the same time he is enabled to receive fresh air as freely as if he were not in the house.

2. **Primary Cryptogenetic Pneumococcus Cerebrospinal Meningitis.**—Cupler reports three cases of cerebrospinal meningitis in which pneumococci were found in the cerebrospinal fluid removed by lumbar puncture. One patient recovered after an illness of five weeks; the other two died at the end of thirty-six and forty-eight hours, respectively. Cupler has found caffein citrate excellent in combating the paralysis of respiration, and recommends lingual traction if stupor is deep and cessation of breathing imminent. Of lumbar puncture he says that it relieves the intracranial pressure, lessens the severity of the symptoms, assists in diagnosis, and meets the requirements of a rational principle in treatment.

3. **Penetrating Gunshot Wound of Abdomen.**—Iden's patient, aged 28 years, was accidentally shot in the abdomen in the region of McBurney's point, with a 32-caliber revolver. About four hours later, the abdomen was opened in the median line and was found full of blood. Nineteen perforations of the small intestine were discovered, as well as several wounds of the mesentery. At one place there were five perforations in four inches of gut, necessitating resection. End-to-end anastomosis was done, using the Cushing suture, and the other perforations were closed with purse-string sutures. The intestines were cleaned with gauze, wet with hot salt solution, and the wound closed without drainage. The operation consumed two and one-half hours, and at its close the pulse was imperceptible at the radial, facial, and temporal arteries, and the heart beats were from 170 to 180 a minute. In spite of the grave condition of shock, the patient rallied very quickly, and the wound healed by primary intention, the man returning to his work, perfectly well, fifty-one days after the operation.

4. **Typhoid with Triple Intussusceptions.**—Bryant and Bragg report this case. The patient was a man, aged 23, who, thirty-eight days after the first symptoms of his typhoid infection, which up to then had run an uneventful course, was suddenly seized with pain in the right iliac region, rise of temperature, and symptoms of shock. A perforation was suspected and the abdomen opened. It was found filled with clear serum, and, on drawing out the small intestine, a short distance from the ileocecal juncture an intussusception was found about eight inches long, invaginated both ways. A short distance further on a second intussusception was found about five inches in length, also invaginated both ways; and, drawing out more gut, there was a third intussusception about three inches long, invaginated from the right. Beyond this the gut appeared normal in color, excepting the infiltrated patches and lymph nodes due to the typhoid infection. Reduction of the invaginations was easily accomplished, but the patient died in shock five hours later.

5. **Unusual Dose of Antitoxin.**—Streett describes a case of scarlet fever, complicated by diphtheria, in which only after 67,000 units of antitoxin had been administered was there any response to treatment. The fresh product of two reliable firms was used. Streett says that the experience teaches the propriety and necessity of continuing the use of antitoxin even when the patient does not seem to respond to it, and the further necessity of increasing the dose administered until such time as results are obtained.

11 Mental and Moral Effects of the Removal of Adenoids. E. A. Huntington, Philadelphia.

7. **Clinical Experiences with Certain Drugs in Heart Disease.**—Satterthwaite regards suprarenal gland as the most powerful heart stimulant known. As to the dangers from the nitrites and nitrates, he finds that their effects are always evanescent. Ordinarily in angina, in hypertension and in arteriosclerosis they are useful, but if they produce violent pulsation in an arteriosclerotic patient they should be suspended.

He says that iodin in some form or other should be the main reliance. Strychnin is a reliable heart stimulant, but should be used with discretion and in moderate doses. Larger doses produce nervousness and insomnia. It should never be continued more than a week or two at a time. Cactus is a good heart regulator, and strophanthus is excellent if prompt action is needed. Digitalis acts best when the arteries are flaccid, and just enough is given to restore normal tension. If the drug produces too much tension, the work of the heart is unnecessarily increased. In acute endocarditis, the fat heart, fatty degeneration, advanced arteriosclerosis, aortic diseases and in cardiac neuroses, digitalis may do serious harm. In deficient or failing compensation, digitalis is useful up to the point of producing normal arterial tension, after which its action is harmful, except in so far as it may increase diuresis. Circulatory depressants, such as antimony, veratrum, pulsatilla and hellebore are out of date, he states, in the treatment of cardiac diseases; but aconite is useful in cardiac neuroses. Satterthwaite places great reliance on camphor. In small doses it is a diffusible stimulant, improving the circulation and relieving arterial pressure, but it is also an antispasmodic and sedative. In threatened heart failure, if the nitrites fail, ammonium carbonate or oxygen, hypodermics of camphor in sterilized oil, may properly be used. Three-hundredths gram (½ gr.) to .13 gm. (2 gr.) may be dissolved in sterilized olive oil and injected hypodermically in divided doses.

8. **Area of Endemic Goiter in Philippines.**—Duncan reports goiter as being very prevalent in the municipality of Macabebe, which is but a few feet above sea level, on the northeast shore of Manila Bay. He ascribes the disease to the lack of potable water and to consanguinity and heredity which favor the continuance of the affection. Duncan estimates that in 1904 there were at least 20 cases per 1,000 of population and that the proportion is probably much greater.

9. **Retroverted Uterus.**—Stoner asserts that in many cases of recent dislocation in which the pelvic floor is intact the uterus may be replaced and retained without the use of instrumentation or operative procedure. A few such patients are permanently cured by prolonged rest, faradism, hot douches, and tamponment with gauze saturated with a preparation of ichthyol and glycerin. The tampon should be changed daily and snugly packed in front of the cervix, in order to prevent it from rotating forward. It thus aids in supporting the uterosacral ligaments. Nearly all supports act largely by their pressure on the uterosacral ligaments, which, in being rendered tense by the posterior upright bar of the pessary, the cervix is swung upward and backward. When, however, the pessary is withdrawn, the ligaments relax and the cervix drops downward and forward.

10. **Struggle Against Tuberculosis in Pennsylvania.**—Wainwright says that local boards of health take no cognizance of tuberculosis except in Philadelphia and in Erie. In Scranton and Pittsburg sputum is examined. In both state prisons efficient measures are being taken to prevent the spread of infection. Five societies have been formed to combat tuberculosis. They are in Philadelphia (state society), Pittsburg, Harrisburg and Scranton. An obstacle to progress in this work is the very general failure to make an early diagnosis and indifference to preventive measures when it has been made. Another serious menace is the general medical dispensary. In one dispensary in Philadelphia, last year nearly 900 people of the poorer classes were treated and in none of them was tuberculosis diagnosed. Wainwright recommends: 1. A state commission on tuberculosis should be appointed to frame legislation governing health boards and to determine the best system for sanatoriums. 2. Compulsory divisions for diseases of the lungs should be enforced in all dispensaries receiving state aid directly or indirectly through the hospitals or schools to which they belong. 3. The State Society for the Prevention of Tuberculosis should be put on a state basis with annual meetings at the same time and place as the state medical society; this society to collect material for an exhibit to be given together with public lectures in each city in which it meets. In this way, each large city in the state would be reached in a few years. The state society should do missionary work and should establish local societies in communities now without them.

13. **Immunity Against Cancer.**—Clowes and Baeslack present the results of studies made by them on cancer immunity. About 1,600 mice have been employed in these experiments relating to the transplantation and development of the Jensen tumors. Thirty mice which had recovered spontaneously of genuine tumors or had been cured of their tumors by serum injection were reinoculated, and of this number 10 were inoculated for the third time. In no case did a tumor develop as a result of inoculation on a mouse which had previously recovered from a true tumor. By mixing cancer materials previous to inoculation with the serum of such spontaneously recovered mice and comparing its effect with that of cancer materials from the same source mixed with serum from normal mice, it was found that the former exerted an inhibiting effect, and that the percentage of tumors is much smaller and the percentage of mice surviving the treatment is larger in the immune than in the normal series. The author feels justified in announcing that all evidence thus far obtained in this field of research is distinctly in favor of the hypothesis that an immune body is present in mice which have recovered spontaneously from malignant tumors.

14. **Female Type of Hand.**—Kingman attempts to establish a characteristic difference in the male and female hand when in a position of extension under normal conditions, believing that further study and observation may show the absence of the sigmoid type in the female and its presence in the male to be of some diagnostic value in conditions of disease. It appears that males who live and work and think on a plane of continued high tension often exhibit the feminine form of hand. The position assumed by the normal female hand is designated by Kingman as the sigmoid carpus. By this is meant a double or S-shaped curve of the wrist and hand involving the portion of the upper extremity from the tips of the fingers to, and including, the lower ends of the radius and ulna. This S curve is made up of two parts, one being formed by flexion at the wrist where the carpus articulates with the ulna and radius, and the other by overexertion at one or more of the three finger joints (the first and second phalangeal and the metacarpophalangeal or knuckles). Viewed from above, the proximal arc of the S is convex and located at the wrist joint, while the distal arc is concave and located at one, two or three of the phalangeal articulations. From below, the reverse, of course, presents a proximal concave joined to a distal convex arc. The sigmoid carpus may best be observed in profile from the ulnar aspect of the hand, the characteristic appearance being somewhat obscured on the radial border by the thumb.

15. ***Diplococci and Pneumococci.***—Palier emphasizes the fact that the only reliable method of diagnosing pneumonia bacteriologically is to obtain cultures from the blood of patients suspected to have this disease. Furthermore, the cultures so obtained must be virulent to mice. Smear preparations or cultures from the sputum are valueless.

22. **Diagnosis of Gall Bladder Disease.**—Graham bases this paper on 135 cases seen by him and followed by operation. He

calls attention to the difficulties met with in diagnosticating disease of the gall bladder, especially when it simulates gastric ulcer, pleurisy, disease of the kidney, pancreatitis, and appendicitis. Particularly difficult of diagnosis are those cases in which the gall bladder contains but one large stone or, at most, a few large ones, and is shrunken down on its contents. In Graham's series there were 13 patients with few stones in the gall bladder; seven had but one, two had two stones, two others had three, and one had six. Of this number, two cases were duodenal ulcer, six had duodenum and stomach given first place, with gallstones or cholecystitis a poor second, five were typical enough to be little questioned as to the real trouble. In the whole series, four cases were diagnosticated duodenal ulcer, five ulcer and gallstones (twice both found), six ulcer of the stomach or perhaps gallstones, twelve were variously called stomach or duodenal ulcer, or appendicitis, too frequently failing to hint at cholecystitis or gallstones. One hundred and six cases were diagnosed without question as gall bladder trouble and the operation proved its truthfulness. In the two remaining cases stones were found when operating for pelvic tumors. One patient had a fibroid uterus, and a stone was found in the common duct with no history elicited. The second gave a history of ovarian tumor with twisted pedicle, but it was not found twisted at the operation and the gall bladder was filled with stones. Twenty-five patients were jaundiced when they presented themselves for examination and one gave a history of jaundice at the first attack. Graham says that this is too large a percentage of jaundice. The diagnosis and operation should be made while still an uncomplicated case of gallstones, when the mortality is extremely small (2.47 per cent.). If we wait for jaundice a complication has arisen which usually greatly increases morbidity and mortality (10.40 per cent.).
